CHAMBERS'S ENCYCLOPÆDIA

A DICTIONARY OF UNIVERSAL KNOWLEDGE

B**eaugency**, an ancient town of France, in the department of Loiret, on the right bank of the Loire, 16 miles SW. of Orleans by rail. It was successively in the hands of the Huns, Saxons, Normans, and English; and it sustained great damage during the religious wars of the 16th century. Here the French army under General Chanzy was severely defeated in a series of desperate struggles, December 7-10, 1870, by the German force under the Grand-duke of Mecklenburg. Pop. 3660.

Beauharnais, ALEXANDRE, VICOMTE DE, born in 1760 of an ancient French family in the island of Martinique; served, under Rochambeau, in the American War of Independence; and in 1789 eagerly embraced the French Revolution, voting, on the night of 4th August, for the abolition of privileges and the political equality of all citizens. As a reward for his constancy to the cause of liberty, he was named Secretary of the National Assembly and subsequently member of the military committee, but largely forfeited his popularity by venturing to praise and defend the conduct of General Bouillé in his sanguinary suppression of the insurrection at Nancy. The illipant manner in which he received the news of the flight of Louis XVI. was eminently characteristic of the man. He merely rose and said to the Assembly: 'Gentlemen, the king has just gone off; let us pass to the order of the day.' In 1793 he declined the office of Minister of War, and tendered his resignation as general of the Army of the Rhine, because it had been determined to exclude the nobility from the service. During the Reign of Terror, his enemies revived the report that he had participated in the surrender of Mainz, because he had remained idle with his troops for 15 days. In consequence of this accusation, he was brought to Paris, tried and sentenced to death by the revolutionary tribunal. He submitted to his fate with firmness,

and died on the scaffold, July 23, 1794. In 1779 he had married Josephine, afterwards wife of the great Napoleon, and his daughter Hortense in 1802 married Napoleon's brother Louis; so that Beauharnais was thus the grandfather of Napoleon III.

Beauharnais, EUGÈNE DE, son of the preceding, was born in 1781, and after his mother Josephine's marriage (1796) with Napoleon, accompanied him to Italy and Egypt. He rapidly rose to the highest military rank; and in 1805 was made a prince of France and viceroy of Italy. In 1806 he married the Princess Amelia Augusta of Bavaria, and not long afterwards was created Prince of Venice, and declared by Napoleon his adopted son, and heir of the kingdom of Italy. Although his political power was much limited, he conducted himself in Italy with great prudence, energy, and moderation, and throughout his life maintained an honourable and virtuous character. His military talents were great, and were displayed particularly in the Italian campaigns, in the wars against Austria, and in the retreat from Moscow, in which he divided with Ney the honour of saving the French army from total destruction. The victory of Lützen was decided by his conduct in that battle. Napoleon sent him from Dresden to Italy, which he ably defended, even after Austria had joined the coalition, and Murat had deserted the cause of the French Empire. In the Hundred Days he took no part; and in the Treaty of Fontainebleau and Congress of Vienna he was allowed to retain his possessions in the March of Ancona; and large sums were granted to him in compensation for his other Italian possessions, with which he purchased the landgraviate of Leuchtenberg and principality of Eichstadt, as Duke of Leuchtenberg taking his place among the nobles of Bavaria. He died at Munich on the 21st February 1824. See the *Lives* by Aubriet (1825) and Baudoncourt (1827), and his *Mémoires et Correspondance*, by Du Casse (10 vols. 1858-60).—His second son, MAX EUGÈNE JOSEPH NAPOLEON

(1817-52), who in 1835 succeeded his elder brother as Duke of Leuchtenberg, married a daughter of the Emperor Nicholas of Russia; and since 1852 his descendants have borne the name of Romanowski, and ranked among the members of the Russian imperial family.

Beaujolais, a subdivision of the old province of Lyonnais, France, which now forms the northern part of the department of Rhône, and a small part of Loire. Its fine vineyards yield the wine called Beaujolais, of which large quantities are exported. Beaujeu was the capital. It formed at first a separate barony; came into the hands of the Bourbons in 1400, was afterwards united to the crown by Francis I., and next passed into the hands of a nephew of the Constable de Bourbon. It came by marriage to the House of Orleans in 1626, with whom it remained until the Revolution.

Beaulieu (pronounced *Bewley*), a village of Hampshire, at the head of a creek, on the verge of the New Forest, 6 miles NE. of Lymington. A Cistercian abbey was founded here by King John in 1204.

Beaully (pronounced *Bewley*), a village, 10 miles W. of Inverness, with remains of a priory founded in 1232. Beaully Firth (7 by 2 miles) is the upper basin of the Moray Firth, and receives the river Beaully, winding 10 miles north-eastward.

Beaumarchais, DE, the name assumed by PIERRE AUGUSTIN CARON, next to Molière, the greatest French comic dramatist. Born in Paris, January 24, 1732, and the son of a watchmaker, he was brought up to his father's trade, and at twenty-one invented a new escapement for watches, which was pirated by a rival. The vigour with which he assailed him soon brought himself into notice at court, where his handsome figure and fine address quickly procured him advancement. He was engaged to teach the harp to the daughters of Louis XV., and ere long the wealthy widow of a court official married him, whereupon he assumed the title by which he was known thenceforward. Duverney, a rich banker of Paris, also befriended him substantially and helped him to some business speculations which realised a handsome fortune, ere long largely increased by another prudent marriage with a wealthy widow. His first plays, *Eugénie* (1767) and *Les Deux Amis* (1770), had but a moderate success. The death of his benefactor Duverney in 1770 now involved the versatile but hitherto unpoplar upstart in a long lawsuit with his heir, Count Lablache, in the course of which he became the idol of the populace, as the supposed champion of public rights against the corrupt tribunals of the old regime. In the first trial Beaumarchais gained his cause, but an appeal to the *parlement* formed by the chancellor Maupeou was decided against him, principally through the exertions of Goetzman, one of its members. Beaumarchais carried his appeal to the public by publishing his famous *Mémoires du Sieur Beaumarchais par lui-même* (1774-78; new ed. by Sainte-Beuve, 1873), a work which united the bitterest satire with the sharpest logic, and gained for him a reputation that made even Voltaire uneasy, who could not bear a rival in his own department. It fitted in with the popular feeling of dissatisfaction with existing institutions, and did much to help on the Revolution. The same brilliant satire burns in two famous comedies, *Le Barbier de Séville*, ou *la Précaution Inutile* (1775), and *La Folle Journée, ou le Mariage de Figaro* (1784). The latter had a most unprecedented success, and indeed for brilliant wit it may almost be put beside the masterpieces of Molière. Figaro was a permanently enduring creation worthy to be compared with the hardly

more famous Tartuffe. These plays are still popular acting plays in France, but in England are chiefly known through the adaptation of them in the grand operas of Mozart and Rossini. The later works of Beaumarchais are hardly worthy of his genius. Further speculations added to his wealth, but his expensive edition of Voltaire's works proved a financial failure. Two later lawsuits cost him his popularity, and in the troubles of the Revolution the shifty but not over-scrupulous author lost his fortune, and, suspected of an attempt to sell arms in Holland to the enemies of the republic, had even to flee from Paris for his life. In *Mes Six Époques* (1793) he has given us an account of his sufferings during that period. In his last years he became quite deaf; he died May 19, 1799. His *Théâtre* has been edited by Saint-Marc Girardin (1861) and by De Heylli and Marescot (1868-72), his *Œuvres Complètes* by Moland (1874) and Fournier (1875). See Lives by Loménie (1873), Lintilhac (1888), and Gudin (1888).

Beaumaris, a seaport and chief town of Anglesey, North Wales, is situated on the west side of the picturesque bay of Beaumaris, near the north entrance to the Menai Strait, 3 miles N. of Bangor, and 239 miles NW. of London. It has the ivy-covered remains of a castle erected by Edward I., and a free grammar-school, and is a favourite sea-bathing resort. The bay is a safe anchorage in stormy weather. Up till 1885, Beaumaris united with Amlwch, Holyhead, and Llangefni in sending one member to parliament. The trade is inconsiderable, but there are some exports of copper and other ores, slates, marble, &c. Pop. (1871) 2291; (1891) 2202.

Beaumont and Fletcher, a pair of the greater dramatists of the Elizabethan age, whose joint work is the result of the most famous of literary partnerships. Francis Beaumont was the younger of the two by about five years, but he died nine years earlier than his friend. He was the third son of Sir Francis Beaumont, one of the justices of the Common Pleas, and was born at Gracedieu, in Leicestershire, in 1584. He was admitted in 1597 as a gentleman-commoner to Broadgate Hall, Oxford (now Pembroke College), and in 1600 to the Inner Temple. Two years thereafter he published *Salvnacis and Hermaphroditus*, an expansion of Ovid's version of the story. Ere long he became an intimate friend of Ben Jonson and the other men of genius who assembled at the Mermaid Tavern, and here no doubt he met the poet with whom he was to form so memorable a friendship. John Fletcher was born at Rye in Sussex, in December 1579. His father was that Dean of Peterborough who disturbed the last moments of Mary Stuart with his ill-timed exhortation, and afterwards as Bishop of London, died either of chagrin at the queen's displeasure on account of his second marriage, or of the immoderate use of tobacco. The boy entered Bene't (now Corpus) College, Cambridge, at twelve, and found himself at seventeen in poverty on his father's death. We know nothing of him until 1607, when he produced the *Woman Hater*. The intimacy which now commenced was one of singular warmth, even for that age when friendships were of a more romantic cast than at present. The two lived in the same house, and had clothes and cloak and everything in common. Aubrey ascribes the 'dearncesse of friendship between them' to a 'wonderfull consimilitude of phansy.' Beaumont married in 1613, but died 6th March 1616. Fletcher wrote on until his death, in his last four years producing no less than eleven new plays. He died in August 1625.

The works of Beaumont and Fletcher comprise

in all fifty-two plays, a masque, and several minor poems; but it is difficult to allocate, in any satisfactory manner, the authorship of these. Professor Ward cannot trace any essential difference between the plays ascribed to both and those attributed to Fletcher alone, while he detects two styles in the plays written by Fletcher along with another than Beaumont. It used to be asserted that Fletcher contributed the vivacity and Beaumont the judgment, and that the latter chastened the exuberant fancies of the former. There seems, however, to be no foundation for this opinion, except the tradition and the fact that Beaumont's own verses are more severe and regular in form than those of the elder poet. Dyce thus assigns the authorship of the plays, with very varying degrees of certainty: By Beaumont and Fletcher, *Four Plays in One, Wit at Several Weapons, Thierry and Theodoret, Maid's Tragedy, Philaster, King and no King, Cupid's Revenge, Little French Lawyer, Coxcomb, Laws of Candy, The Knight of the Burning Pestle, and The Scornful Lady*; by Beaumont alone, the *Masque*; by Fletcher and Massinger, *False One, Very Woman, The Lover's Progress*; by Fletcher and Rowley, *Queen of Corinth, Maid of the Mill, Bloody Brother*; by Fletcher and Shirley, *Noble Gentleman, Night Walker, Love's Pilgrimage*; by Fletcher and Shakespeare, *The Two Noble Kinsmen*; the remaining plays by Fletcher alone. Fletcher's collaborateur in some of the later plays is, however, entirely uncertain. His own versification has many peculiar features which make his verse distinguishable from that of his contemporary dramatists. The chief of these is the frequency of double or feminine endings, in which he may be safely said to exceed any other writer of our old drama. According to Mr Fleay, the average of such endings in the plays as to all of which he and Dyce agree in considering Fletcher the sole author is 177; that in the plays of Massinger, the dramatist next to Fletcher most given to the practice, 1059. Again, in the plays known to have been written by Fletcher alone, rhyme is used very sparingly, and prose is eschewed altogether. Professor Ward observes that the double-endings, particularly as used by Fletcher in combination with the practice of stopping the sense at the end of the verse, give so peculiar a cadence to the lines, and constitute a manner of versification from which when once adopted a poet is so unlikely incidentally to diverge, that their frequent employment in scenes of joint plays and their sparse employment in other scenes, may be fairly regarded as favouring the antecedent supposition of the presence or absence of Fletcher's hand. At the same time, too much may well be made of such mechanical tests, and it may be permitted to leave a problem that so acute a critic as the late Mr W. B. Donne regarded as insoluble in the pious uncertainty of the stationer's address to the courteous reader in the first folio edition of 1647 (the earliest, though that of 1679 was the first complete edition): 'It was once in my thoughts to have printed Mr Fletcher's works by themselves, because single and alone he would make a just volume; but since never parted while they lived, I conceived it not equitable to separate their ashes.' Fletcher undoubtedly had a share in Shakespeare's *Henry VIII.* The touch of Shakespeare is felt with considerable certainty in *The Two Noble Kinsmen*. There is a tone of music and a tread of thunder in some of the passages, to which no parallel can be found in any of the companion dramas. Only three plays were, during Fletcher's lifetime, published as joint productions. Two of these—*Philaster* and *The Maid's Tragedy*—are, with the exception of the great passages in *The Two Noble*

Kinsmen, the glory of the collection. The question has been often discussed, why these plays are called by the name of Beaumont and Fletcher, thus giving precedence to the younger and less voluminous writer. Mr Dyce's opinion is that of the three plays published as joint productions during Fletcher's life, Beaumont either had the greater share, or that, through feelings of natural courtesy, Fletcher placed the name of his deceased associate before his own, and that future editors naturally followed the arrangement which they found to their hand. From all that can be gathered, it would appear that Beaumont possessed the deeper and more thoughtful genius; Fletcher the gayer and more idyllic. There is a strength as of granite rock in *The Maid's Tragedy*; there is a glad exuberant music, and a May-morning light and freshness in *The Faithful Shepherdess*, which Milton did not disdain to accept as a model in the lyrical portions of *Comus*, and of which the *Endymion* of Keats is but an echo. The plays of Beaumont and Fletcher never sound the deep sea of passion; they disport themselves, dolphin-like, on its surface. They are poets first and dramatists after; and indeed display but little power of serious and consistent characterisation, while they are much too fond of unnatural and violent situations. Morally, little can be said in their praise. Even that most delightful pastoral *The Faithful Shepherdess* is marred by deformities that interfere with its harmonious beauty. 'A spot,' says Charles Lamb, 'is on the face of this Diana. Nothing short of infatuation could have driven Fletcher upon mixing with this "blessedness" such an ugly deformity as Cloe, the wanton shepherdess!' The best edition is that of Dyce (11 vols. 1843-46), which superseded its chief predecessor, that of Weber (1812). See A. W. Ward's *History of English Dramatic Literature* (2 vols. 1875); Fleay's *Shakespeare Manual*; G. C. Macaulay's *Francis Beaumont, a Critical Study* (1883); and the bibliography by A. C. Potter in *Bibliographical Contributions of Harvard University* (1891).

Beaumont. EON DE. See EON DE BEAUMONT.

Beaumont, JEAN BAPTISTE ÉLIE DE, born in 1798 at Canon, in Calvados, taught geology in the École des Mines and Collège de France, was elected to the Academy in 1835, and became in 1856 its perpetual secretary. He died 22d September 1874. With Dufrenoy he prepared a great geological map of France (1840; 2d ed. 1855); and see MOUNTAINS, Vol. VII. p. 334.

Beaumont, SIR GEORGE HOWLAND, landscape painter and patron of art and artists, was born at Stonehall, Dunmow, Essex, 6th November 1753, and studied at Eton and New College, Oxford. He was an intimate friend of Sir Joshua Reynolds, entertained Wordsworth at his house of Coleorton, in Leicestershire, where Scott, Rogers, and Byron met, befriended Coleridge and the painters Wilkie, Haydon, and Landseer, and presented his valuable collection of pictures to the National Gallery. He died 7th February 1827. See *Knight's Memorials of Coleorton* (1887).

Beaumontague is a composition of iron borings, brimstone, pitch, sal-ammoniac, rosin, and beeswax, which is used to fill up cracks and flaws in an iron casting, to give an appearance of solidity.

Beaune, a well-built town in the French department Côte d'Or, 23 miles SSW. of Dijon by rail, with a fine parish church, Notre Dame (13th century); a splendid hospital, founded in 1443 by Nicholas Rollin; and a bronze statue (1849) of Monge the mathematician. It manufactures serges, woollen cloth, and cutlery, and is a chief seat of the Burgundy wine trade, Beaune giving name to

one of the best Burgundies. During the Franco-German war in 1870, the town was several times occupied by the Germans. Pop. 11,755.

Beaune. FLORIMOND DE, a mathematician and friend of Descartes, born in 1601 at Blois, in France, served as a soldier, and died at his native place in 1652. His labours and discoveries contributed greatly to the improvement of the modern analytical geometry first introduced by Descartes. He is well known through 'Beaune's Problem,' solved with the help of the integral calculus by Jean Bernoulli in 1693, which turns on the determination of the nature of a curved line from a property of its tangent.

Beauregard. PIERRE GUSTAVE TOUTANT, Confederate general, was born in 1818, near New Orleans, graduated at West Point in 1838, served with distinction in the Mexican War, and after its close superintended the engineering works on the Lower Mississippi and the Gulf of Mexico. He joined the secession with his native state, and was appointed by the Confederate government to the command at Charleston, S.C., where, April 12, 1861, he commenced the war by the bombardment of Fort Sumter. He was virtually in command at the first battle of Bull Run, July 21, 1861; and sent to the west in the spring of 1862 as second to General A. S. Johnston, he succeeded to the command when the latter was killed in the first day's battle of Shiloh or Pittsburg Landing. Defeated on the second day's fighting, he retreated to Corinth, Miss., where he reorganised his division; but on the approach of the Union troops he evacuated the place, and was superseded by General Bragg. After a period of inactivity he was placed (1864) in command of the military division of the west, but failed to check Sherman's march to the sea. After the war, he was president of a railway, and manager of the Louisiana State Lottery. He died 21st February 1893.

Beausobre. ISAAC DE, Huguenot preacher and writer, was born at Niort, in Poitou, in 1659, studied theology at Saumur, and after his ordination had charge of a church at Châtillon-sur-Indre. The revocation of the Edict of Nantes, in 1685, obliged him to flee to Holland. In 1694 he went to Berlin, became chaplain of a French Protestant church there, and councillor of the royal consistory. Among his works were an *Essai critique de l'Histoire de Maniché et du Manichéisme* (1734-9), which Gibbon characterises as a rich treasury of facts and opinions; and along with M. Lefant, a translation of the New Testament, with notes. He was a chief contributor to the voluminous *Bibliothèque Allemande*. He died at Berlin in 1738.

Beauty. See *ÆSTHETICS*, ART.

Beauvais, a town of France, capital of the department Oise, situated in the valley of the Thérain, 55 miles NNW. of Paris. Among several fine buildings the most noteworthy is the unfinished cathedral, begun in 1225, the choir of which, 153 feet high, is the loftiest as well as one of the finest specimens of Gothic in France. The industries of Beauvais include the weaving of Gobelin tapestries (since 1664), and the manufacture of cotton, woollen cloths, shawls, and carpets. Pop. (1891) 19,275. Beauvais was known by the Romans as *Cesaro-magus*, afterwards as *Belloracum*. In 1472 it was besieged by Charles the Bold of Burgundy, with an army of 80,000 men, when the women of Beauvais, under the leadership of the heroine Jeanne Hachette, displayed remarkable valour. The standard which the Burgundians had planted on the wall was torn down by Jeanne, and borne off by her in triumph. The banner is borne every year by young girls in a procession, and a statue of Jeanne was erected in 1851.

Beaver (*Castor*), a familiar rodent mammal, allied to squirrels and marmots, and represented by a single widely distributed species (*Castor fiber* or *canadensis*). It is widely known for its aquatic habit, its sagacious architectural devices, its glossy fur, and its fatty castoreum glands.

Form and Structure.—The beaver is usually about 2½ feet in length, and is thus hardly surpassed by any other rodent except the Capybara (q.v.). It stands rather under a foot in height, and the broad, flat, scaly tail is about 10 inches long. The body is plump, the back arched, the neck thick, the hind-feet webbed, and all the digits clawed. The strong wrist has an accessory bone. The fur varies considerably in colour, but is usually reddish-brown above, and lighter or grayish below. The short head runs out into a naked muzzle; the external ears are short and scaly, and admit of being folded, so as almost to shut the opening; the eyes are small; and the nostrils closable. The skull is massive, with marked ridges for fixing the muscles which work the jaws, and both size and ridges increase throughout life. The two front teeth on either jaw are like those of other rodents, wearing away more rapidly behind so as to leave a sharp enamelled chisel edge. They have a bright orange colour. They grow as usual from persisting pulps, so that what is worn away in gnawing is continually being replaced at the root. The four grinding teeth on each side of each jaw are nearly equal to one another, and exhibit two or three infoldings of the enamel coating. The stomach has near its commencement a peculiar glandular structure; the external relations of anal and urinogenital apertures resemble those of marsupials; and the male bears on its groin a pair of glands which secrete a substance known as *Castoreum*.

Distribution.—The beaver, though represented only by a single species, is widely distributed in the northern parts of both eastern and western hemispheres. It is rapidly disappearing from countries where it previously flourished, being now, for instance, extinct in Britain, and apparently also in Scandinavia. An attempt has been made to reintroduce it in Bute. Isolated colonies of beavers are still to be seen where they have been protected from molestation on the Elbe and a few other rivers in Germany and Austria; but they can hardly be said to be really at home in Europe except in Russia and Poland, and 'especially on the streams of the Ural Mountains, and those emptying into the Caspian Sea.' They are also abundant in Siberia. The American beaver, which is probably only a variety, and not a distinct species, is found to the west of the Mississippi, between Alaska and Mexico, and more sparsely to the east of the same river, to the south of the Great Lakes, in the Maine and Adirondack wildernesses, and yet more sparsely southward to Alabama and Mississippi. They are also frequent in some parts of Virginia and Pennsylvania (see Heilprin, *Distribution of Animals*, International Science Series). Several extinct species of beaver have been dug up from Miocene and Pliocene strata. *Castoroides ohioensis* was an allied giant rodent about as big as a black bear. Another large extinct rodent, which Owen described under the title 'Trogontherium,' is regarded by some as a giant beaver.

Habits.—Beavers are well known to be aquatic animals, and are never found far away from river or lake. Their webbed hind-feet make them capital swimmers. They also dive well though noisily, and can remain two minutes under water. They feed mainly on the bark of trees, such as willows, magnolias, poplars, and birches, but also on the roots of the water-lily and other plants, and

on their inland excursions during the warm season on fruits, corn, and the like. They often sit on their hind-feet and tail, eating with their fore-paws like squirrels. They are, however, pre-eminently bark-eaters, and large quantities of wood are stored up in the autumn for winter use. When the streams are frozen, they may remain for as long as a fortnight comfortably provided with supplies within their burrows. Most of the beavers' active life is during the night, except when floods force them to abandon their homes. They may be readily tamed, but cannot of course be kept in wooden houses. They may be seen in the London Zoological Gardens, and occasionally in aquariums.

Family-life.—Beavers are social animals; a family of about half a dozen is frequently found within a single house, and where food is abundant and the locality secluded, a large number of families occur congregated in a community. The young beavers leave the parent house in the summer of their third year, find mates for themselves, and establish new homesteads. When increase of population brings about difficulties of subsistence, a migration takes place, some going up and others down the stream. The old houses are never left vacant, however, but are simply transferred by the emigrants to some related new couple. Isolated males or terriers, apparently expelled from a colony for laziness or misbehaviour, are often found living alone.

Homes.—The simplest beaver home is merely a burrow, and when their tenure seems insecure, as in populous countries, the beavers may remain contented with this mode of life. These burrows open outwards under the water, and are thus effectively concealed. Mr L. H. Morgan, in his work on the American beaver, regards the burrow as the primitive and normal residence from which 'in the progress of experience, by a process of natural suggestion,' the more elaborate homes have been gradually evolved. Beaver architecture, as well as human, has had its history. Above the burrow a surface-pile of sticks is often found, perhaps to keep the snow loose enough overhead to admit air, and from these ventilating piles 'it is but a step to a lodge with its chamber above ground, and the previous burrow as an entrance from the water.' 'A burrow accidentally broken through at its upper end, and repaired with a covering of sticks and earth, would lead to a lodge above ground, and thus inaugurate a beaver-lodge out of a broken burrow.'

The Lodge.—However it may have arisen, the so-called beaver-lodge is a marvellous structure. Three distinct kinds can be distinguished in adaptation to different localities. The island-lodge is constructed on a small island in the pond or dam. It consists of a central chamber, with its floor a little above the level of the water, and with two entrances. One of these—the 'wood entrance'—is a straight incline rising from the water, and opening neatly into the floor of the hut. Up this the pieces of wood used for winter food are passed. The other approach—the 'beaver entrance'—is more abrupt in its descent to the water, and often tortuous in its course. Both approaches, which are often many feet in length, are neatly lined and finished off, especially where they open into the central chamber. The lodge itself is an oven-shaped house of sticks, grass, and moss, woven together and plastered with mud, increasing gradually in size with year after year of repair and elaboration. They are not only comfortable, but efficiently protective against beasts of prey. The room inside may measure 8 feet in diameter, and 2 or 3 feet in height. The floor is very comfortably carpeted with bark, grass, and wood-chips, and

there are sometimes special store-rooms adjoining. The entrances open into a specially deep moat surrounding the home, and as this is too deep to freeze readily, the inmates are not apt to be imprisoned even by very keen frost. Another kind

Beavers and Beaver-lodge.

of lodge is built on the bank of a stream or pond, either a short way back from the edge, or partly hanging over, with its front wall built up from the bottom of the pond. A third type—the so-called 'lake-lodges'—are built on the shelving shores of lakes, with a large part of the hut built out upon the water. The various forms of house, all apparently modifications of the primitive burrow, are of much interest, as illustrating the beaver's power of adapting its constructive powers to different local conditions. Mr Morgan also directs attention to the 'beaver-slides' or cuttings seen on the Upper Missouri, where the banks are too vertical to admit of the ordinary construction without some previous surface-work. In certain localities—for instance, in California—the animals have either relapsed from their ordinary architectural labours, or have never fully developed the constructive habit. Hunters often break into the lodges so as to drive the beavers into the holes or burrows.

Wood-cutting.—Some of the most interesting habits of beavers are connected with the way in which they procure and store their food-material. That they are bark-eaters has been already noticed, and it is an equally familiar fact that in order to procure this they cut down trees by gnawing a ring round the base. This they cut all round, but more towards the side nearest the water, so that the tree may fall as conveniently as possible. They can cut down a tree 10 inches or so in diameter. The smaller branches with more palatable bark are cut off in the same way, and cut into lengths convenient for transport and storage. The heavier pieces are ingeniously rolled along, often for a considerable distance, to the water-edge. Sometimes the tree is near enough to fall at once into the water, and is simply left till required, but such a convenient supply is soon exhausted. When a block has been rolled to the water-edge it is floated out to the lodge, and either anchored by means of brushwood stuck into the bottom of the pond, or sunk to the mouth of the 'wood entrance,' and conveyed up into the lodge. Barked branches from which the nutritive portion has been eaten away, may be further used, as already indicated, for building the lodges.

Beaver-dams.—Yet more marvellous are the dams

by which beavers widen the area and increase the depth of water round about their homes. These vary in structure according to the nature of the locality. They are either made of sticks and poles, with a slight embankment of earth, not enough to prevent the surplus water flowing freely through, or they are constructed more firmly and solidly of mud, brushwood, and stones, with a special outlet on the ridge for the discharge of the overflow. Though beavers do not hammer in poles, nor use their tails as trowels, they exhibit marvellous ingenuity in the construction of their dams. The stones and mud are cleverly carried by the fore-paws, the burden being pressed against the chest; the curvature of the dam is adjusted to the direction of the current; a constant level of water is secured by modification of the outlet sluice; the wear is continually remedied by fresh building; auxiliary dams are constructed to all appearance simply for the purpose of breaking the flow of water in the main dam, and so on. Some of these dams have prodigious dimensions. Mr Morgan describes one structure '1530 feet in length, of which 530 feet in two sections is artificial, and the remainder natural bank, but worked here and there where depressions on the ground required raising by artificial means.'

Canals.—Mr Morgan has also discovered and described the construction of waterways or canals, which the beavers dig between their ponds and the sources of timber-supply. When the trees near the water are exhausted, and when the uneven character of the ground makes the rolling of the logs a difficult task, canals are cut for convenience of transport. In certain cases the construction of a big dam may bring the water-edge quite near enough the trees, but this is not always so. The construction of canals becomes as necessary as it is marvellous. They may be hundreds of feet long, increasing in length as the trees are gradually cut away, and are usually about a yard or more in breadth, and 3 feet or so deep. Sometimes, however, the ground rises suddenly at a certain distance from the pond, so that a continuous canal becomes impossible. In such a case an engineer constructing a canal would make a 'lock.' This is exactly the solution of the difficulty which has been arrived at by beavers. Mr Morgan describes a case where three water-collecting crescent-shaped dams have been made, at three successive sudden ascents of the ground, and the principle of locks ingeniously combined with that of collecting reservoirs. In another case the canal bifurcates at the foot of the woodland slope, and thus presents a maximum water-edge. Or again, these acute engineers have been observed to make a short-cut waterway across the ground inclosed in a loop of the river, so as to lessen considerably the distance of transport.

Geological Interest.—All this work of burrowing, timber-felling, dam-building, canal-cutting, carried on continuously by generation after generation of beavers, must in no inconsiderable way have affected the minuter features of a landscape. Agassiz has estimated the age of one of these beaver dams at a thousand years. As the result of beaver work, large tracts once covered with trees have become bare, and what was once dry meadow has been flooded with water. Acres of what once was forest land are represented now by peaty clearings, and still remain as 'beaver meadows' in countries from which the busy foresters have long since disappeared.

Practical Uses.—The beaver has for long been hunted for the sake of its fur, from which both hats and gloves were made. Chancer speaks of a 'Flandrish beaver hat' about 1386, and we have 'brown beaver gloves' in Dickens' *Sketches by Boz* (1836). An act of the English parliament, in

1638, prohibiting the use of any other material for hat-making, contributed to the rapid diminution of the number of beavers in the parts of North America from which their skins were then obtained (see HAT). During a great part of the 18th and the earlier part of the 19th century, the number of beaver skins annually exported from America appears to have been not less than 200,000. It is now greatly diminished, but is still large. From very ancient times the secretion of the gland, on the groin of male beavers, has been valued on account of its curative properties. So far as the beavers are concerned, the strong-smelling substance is apparently subsidiary to sexual attraction. Hunters are said to utilise it as bait for their traps. The so-called castoreum contains oily and resinous substances, along with a crystallisable component known as castorine, once largely employed in medicine as a nervous stimulant. Mythical stories are told of the way in which beavers throw themselves on their backs when pursued by hunters, so as to expose the wished-for glands, with a hint that their lives might be spared; according to the credulous they may even bite off the glands and leave them as a ransom. The oily flesh is said also to be esteemed by the trappers. The fat tail is a special delicacy, and the animal being popularly regarded as a fish, may be eaten during Lent.

Intelligence.—Enough has been said to show that the habits and labours of beavers exhibit more marks of sagacity than can possibly be the result of hereditary habit. They do much more than follow a hard and fast path of orderly and purposeful action—they can adapt their actions to varying conditions in a manner which can only be described as rationally intelligent. The Indians go further, and invest the beaver with immortality. The reader should consult Lewis H. Morgan on *The American Beaver and his Works* (1868), or Romanes on *Animal Intelligence* (1886), and on *Mental Evolution in Animals* (1886), and Horace T. Martin's *Castorologia* (1892).

Beaver Dam, a city at the outlet of Beaver Lake, Wisconsin, U.S., 61 miles NW. of Milwaukee, on the Chicago, Milwaukee, and St Paul Railway. It is the centre of a fertile district, and has a university, various factories, and flour-mills. Pop. (1880) 3441; (1890) 4222.

Beaver Falls, a village of Pennsylvania, U.S., near the junction of the Beaver River with the Ohio, 34 miles NW. of Pittsburg. The 'Harmony' Society of Economy controls most of the manufacturing here. Pop. (1880) 5104; (1890) 9735.

Beaver Wood. See MAGNOLIA.

Bebeerine, or BEBERINE, is an alkaloid obtained from the greenheart bark or *bebeeru* of British Guiana, first separated and described in 1843 by Sir Douglas MacLagan of Edinburgh. Recent investigations seem to show that this alkaloid is identical with *Buxine*, which is obtained from the bark and leaves of the common box, and it is probable that it is also present in some other plants. It was hoped that bebeerine, in the form of sulphate, would become a substitute for quinine; but it is not so powerful in its action as a tonic and febrifuge, and has not therefore come into popular use. Bebeerine is always prescribed in the form of sulphate, a dark amorphous substance, obtained in thin translucent laminae by spreading the sirup solution on sheets of glass, and allowing it to dry. See GREENHEART.

Bebek, a lovely bay on the European side of the Bosphorus, with a palace of the sultan, known as the *Hunayunabad*, and built in 1725. Here also are the establishments for baking biscuits for the fleet, an American school, and a college of the French order of Lazarists.

Bebel, FERDINAND AUGUST, social democrat, born at Cologne in 1840, in 1860 came to Leipzig, where four years later he established himself as a master turner. Since 1862 engaging fanatically in the labour movement, he was elected in 1867 to the North German Diet, in 1871 to the Reichstag. In 1872 he was sentenced to two years' imprisonment. Among his writings are *Der Deutsche Bauernkrieg* (1876), and a work on the status of women (1883).

Bec Abbey, the ruins of which are at Bee-Hellonin, Normandy, 23 miles from Brionne, was at the height of its fame as a great Benedictine monastery in the middle of the 11th century, when the famous Lanfranc was prior. His fame as a scholar had made it one of the most renowned seats of learning in Western Europe, students flocked thither from all parts, and gifts were bestowed upon it by the great men of Normandy. The great Anselm, entering it in 1060, was abbot from 1078 to 1093, when he succeeded Lanfranc in the see of Canterbury.

Beccafico (*Sylvia hortensis*, of *Curruca hortensis*), a little bird of the family of the Sylviadæ, or Warblers (q.v.), sometimes called the Petty-chaps, and sometimes the Garden Warbler, rather rare in Britain, but abundant in some of the more southern parts of Europe, and in great demand for the table in Italy, its flesh being regarded as of peculiar delicacy. It is a mere summer bird of passage, however, not only in Britain, but even in the south of Europe. The upper parts are mostly of a brown colour, the lower parts whitish. It is a bird of very pleasing song. Beccafico is an Italian name signifying 'fly-pecker,' and is sometimes extended to other birds of the same family used for the table.

Beccamoschino (Ital., 'fly-catcher'; *Sylvia cisticola*), a little bird of the family of Warblers, found in Italy. It is remarkable for its nest, which resembles that of the tailor-birds, and is usually placed in a bush with long leaves, which are neatly sewed together with some kind of vegetable fibre so as to form roof and floor.

Beccaria, CENSARE, MARCHESE DE BECCARIA-BONESANA, a political and philanthropic writer, was born at Milan, March 15, 1735 (or in 1738). His opinions were formed by study of the French encyclopædists and Montesquieu. His chief work was his *Dei Delitti e delle Pene* ('On Crimes and Punishments'), first published anonymously at Monaca in 1764, in which he argues against the severities and abuses of criminal law, especially capital punishment and torture. The work became extremely popular, and was translated into all the European languages. It was hailed with enthusiasm by the French school, and commentaries were published by Voltaire and Diderot. A translation of it, with a life of Beccaria, was published by J. A. Farren in 1880. It is marked by eloquence, sensibility, and lively power of imagination. Kant unfairly accuses the author of an affected humanity, though it must be admitted that the German philosopher has exposed the invalidity of some of the arguments brought forward. On the whole, however, the work of Beccaria is acknowledged to have done great good, and the subsequent reforms in the penal code of European nations have generally taken the direction he has pointed out. He was among the first to advocate the beneficial influence of education in lessening crime. Both his arguments and his popularity made him many enemies, but their malice was frustrated by the efforts of Count Firmian, the Austrian governor of Lombardy, a man of liberal and enlightened sentiments. In 1768 Beccaria was appointed professor of Political

Philosophy at Milan, and achieved great success as a lecturer. In 1791 he was made a member of the board for the reform of the judicial code, and had the triumph of seeing several of his abused suggestions adopted. He died of apoplexy, November 28, 1794.—GIACOMO BATTISTA BECCARIA (1716-81) from 1748 was professor of Physics at Turin, and did much to forward the science of electricity, though himself he made no important discovery.

Beebles, a Suffolk market-town, on the Waveney, 8 miles W. of Lowestoft. It has a fine church with a detached belfry, a good grammar-school, and large printing-works. Pop. (1891) 6669.

Bec-fin, the common French name for different species of birds of the family Sylviadæ, or Warblers (q.v.).

Bêche de Mer. See TREPANG.

Becher, JOHANN JOACHIM, chemist, was born at Spire in 1635. He acquired an extensive knowledge of medicine, physics, and chemistry, and became professor at Mainz. He subsequently lived at Vienna, Munich, Würzburg, Haarlem, and finally London, where he died in 1682. He was accused of charlatanism, but unquestionably he rendered important services to chemistry. His *Physica Subterranea* (1669) was the first attempt made to bring physics and chemistry into close relation. He began to construct a theory of chemistry, and investigated the process of combustion. In this and his other works (including *Institutiones Chymicæ*, 1662) lies the first germ of Stahl's phlogistic theory.

Bechuanaland, an extensive tract in South Africa, inhabited by the Bechuanas, extending from 28° S. lat. to the Zambesi, and from 20° E. long. to the Transvaal border. The Bechuanas also still occupy a considerable portion of the Transvaal, from which the Boers never wholly expelled them. British protection extends over Bechuanaland as far as 22° S. lat. since 1884; more northward, it is under the Imperial British South Africa Company (see ZAMBESIA). To the south of the river Molopo the territory has been a crown colony since 1885; and this has an area of 51,000 sq. m. (larger than England without Wales), and a pop. (1891) of 60,376—5524 being whites. The protectorate beyond has an area of 120,000 sq. m.—larger than the Transvaal, and almost as large as Great Britain and Ireland.

Bechuanaland is a portion of an elevated plateau 4000 to 5000 feet above the level of the sea, and though so near the tropics, is suitable for the British race. In winter there are sharp frosts, and snow falls in some years. The rains fall in summer, and then only the rivers are full. It is an excellent country for cattle; sheep thrive in some parts, and there are extensive tracts available for corn-lands; but it is not a wheat country on account of the summer rains. Though apparently subject to droughts, it is not more so than the Cape Colony, and the greater portion will be available for farming operations when the necessary dams have been constructed. It can be reached from Capetown, Port Elizabeth, Durban, Delagoa Bay, and the Zambesi. There are extensive forests to the north-east, and to the west the Kalahari Desert, which only requires wells dug to make it inhabitable.

The enormous quantities of buck which roam over the land attest the productiveness of the soil. Gold has been found near Sitlagoli, and there are indications of gold-bearing quartz reefs in many directions. Diamondiferous soil is also said to exist in several localities; indeed, diamonds were discovered at Vryburg in the autumn of 1887.

The province of Stellaland is principally inhabited by Boers, and the remainder of the country by Bechuanas. The Bechuanas are a black race,

possessing a language in common with the Bantu (q.v.) races of South Africa, extending as far north as the equator. Their ancestors are said to have come from the north, and, progressing south-west, met the Hottentots from the Cape of Good Hope journeying north. The Bechuanas have divided up within the last 150 years, and comprise the Bahurutse, Bamangwato, Bakwena, Bangwaketse, Barolongs, Batlapins, and Batlaros. Each tribe has an animal as an emblem or heraldic sign, which it is said they hold in esteem (see TOTEMISM). They have since 1832 been at enmity with the Matabele, and in later years the Transvaal Boers have on one pretext or another endeavoured to occupy their country. During the native risings in 1878, the Bechuanas invaded Griqualand West, and were in turn subdued by British volunteers as far as the Molopo. When the British government withdrew from Bechuanaland in 1880, the natives, being helpless, were left to the mercy of the Boers of the Transvaal, whose harsh treatment in 1882 and 1883 led to the Bechuanaland expedition in 1884. At the beginning of the 19th century, the Bechuanas were further in advance in civilisation than other nations of South Africa, and they are still ahead in this respect. All important matters are decided in the public assembly of the freemen of the town, but matters are previously arranged between the chief and headmen, the chiefs exercising real control only by personal influence and adroitness. Since 1895 the Crown Colony has been incorporated with the Cape Colony, the Governor of the Cape being represented by an administrator at Vryburg; while in the Protectorate, Khama (q.v.) and the other chiefs rule under the protection of the Queen, a resident commissioner representing the High Commissioner of the Cape. The Kuruman Mission of the London Society has done good work among the Bechuanas. See Mackenzie's *Austral Africa* (1887) and books named at CAPE COLONY.

Becker, KARL FERDINAND, German philologist, was born at Liser, in the old electorate of Treves, in 1775. For five years a teacher, he afterwards studied medicine, and finally, in 1815, settled as a practitioner at Offenbach. Here he educated his own children with such success that several families induced him to take charge of theirs, and thus his house was converted into an academy (1823), which he conducted till his death in 1849. He wrote an *Ausführliche Deutsche Grammatik* (1836-39), and several other valuable treatises on the German language.

Becker, KARL FERDINAND, a German musician, born at Leipzig in 1804, at the age of fourteen made his first public appearance as a pianist. In 1843 he was appointed professor of the Organ at the Leipzig Conservatorium. His compositions for the organ have some value, but he is best known as a writer on the history of music, and as an important contributor to German musical periodicals. His collection of *Chorales* (1831), and *Die Hausmusik* (1840), are highly valued. He died October 26, 1877.

Becker, WILHELM ADOLF, born at Dresden in 1796, studied theology and philology at Leipzig, and became in 1842 professor of Archaeology there. He died at Meissen, 30th September 1846. His lively fancy, aided by a thorough knowledge of the classic languages, enabled him to make a novel use of antiquity. In his *Charicles* (1840), he ventured to reproduce the social life of old Greece; and in his *Gallus* (1838), to give sketches of the Augustan age at Rome. His *Handbuch der Römischen Alterthümer* (1843-46) was, after his death, continued by Marquardt (vols. iii.-v. 1849-68).

Beckerath, HERMANN VON, a German politician, was born at Krefeld, Prussia, 13th December 1801. He made a considerable fortune as a banker, and in 1843 was elected representative of his native town in the provincial diet. Elected to the National Assembly at Frankfurt in 1848, he was appointed minister of finance, and shortly after called to Berlin to construct a cabinet; but in this he failed. He was a resolute advocate for German unity. In 1858 he was again elected a member of the Prussian second chamber; but declined the honour on account of failing health. He devoted his later years to the affairs of his native town, where he died 12th May 1870. See *Life by Kopstadt* (Brunswick, 1874).

Becket, THOMAS, Archbishop of Canterbury, was born in London in 1118 of Norman parentage, his father being a wealthy merchant. That his mother was a love-lorn Saracen is a pretty but wholly baseless tradition. Educated at Merton Priory and in the London schools, he was trained in knightly exercises at Pevensey Castle, next studied theology at Paris, and then, on his father's failure in business, was clerk for three years in a lawyer's office. About 1142 he entered the household of Theobald, Archbishop of Canterbury, who sent him to study canonical jurisprudence at Bologna and Auxerre, heaped preferments on him, including the archdeaconry of Canterbury (1154), and employed him in several important missions. At the papal court in 1152 he had promoted the cause of Henry of Anjou against that of Stephen's son, Eustace; in 1155, the year after Henry's accession, he received the office of chancellor, and thus resuscitated the hopes of the English as the first Englishman born, since the Conquest, who had filled any high office. His duties as chancellor were numerous and burdensome, but he discharged them vigorously. So magnificently liberal was he in his hospitality, that Henry himself did not live in a manner more sumptuous. He fought like any knight in the war with Toulouse (1159), and would seem in everything to have regarded himself as a mere layman, though he held deacon's orders. The change, then, was all the more sudden when in 1162 he was created Archbishop of Canterbury, an office which, as it then involved the abbacy of the cathedral monastery, had never but twice before been held by any but a monk or canon-regular. He resigned the chancellorship, threw aside all his old courtly and luxurious habits, turned a rigid ascetic, showed his liberality only in charities, and in short became as zealous a servitor of the church as ever before of king or archbishop. He figured soon as a champion of her rights against all aggressions by the king and his courtiers, several nobles and other laymen being excommunicated for their alienation of church property. Henry II., who, like all the Norman kings, endeavoured to keep the clergy in subordination to the state, in 1164 convoked the nobility and clergy to a council at Clarendon (q.v.), where were adopted the so-called 'Constitutions,' or laws relative to the respective powers of church and state. To these, curtailing clerical immunities, the primate at first declared he would never consent; but afterwards, through the efforts of the nobles, some of the bishops, and, finally, of the pope himself, he was induced to give his unwilling approbation. Henry now began to perceive that Becket's notions and his own were utterly antagonistic, and clearly exhibited his hostility to the prelate, whereupon Becket tried to leave the country. For this offence Henry charged him with breach of allegiance, in a council held at Northampton, confiscated his goods, and sequestered the revenues of his see. A claim was also made on him for not less than 44,000 marks, as the balance due by him to the crown when he

ceased to be chancellor. Becket appealed to the pope, and next day leaving Northampton in disguise, escaped to France. He spent two years in retirement at the Cistercian abbey of Pontigny in Burgundy; and then, the pope seeming disposed to take up his cause, he went to Rome, and pleaded personally before his holiness, who reinstated him in the see of Canterbury. Becket now returned to France, and thence he wrote angry letters to the English bishops, threatening them with excommunication. Several efforts were made to reconcile him with Henry, which, however, proved futile; but at length in 1170 an agreement was patched up at Freteval, on the borders of Touraine. The result was that Becket returned to England, entering Canterbury amid the rejoicings of the people, who were unquestionably proud of him, and regarded him—whether wisely or not is another question—as a shield from the oppressions of the nobility. Fresh quarrels soon broke out; excommunications were renewed; and Henry at last exclaimed: 'Of the cowards that eat my bread, is there none will rid me of this turbulent priest?' Four knights—Fitzurse, Tracy, Brito, and Morville—overheard the hasty words; and, quitting Normandy by separate ways, on the evening of 29th December 1170 entered Canterbury cathedral, and slew the archbishop before the altar of St Benedict, in the north transept. Henry was compelled to make heavy concessions to avoid the ban of excommunication. The murderers, having repaired to Rome as penitents, were sent on a pilgrimage to Palestine; and, two years after his death, Becket was canonised, and the anniversary of his death set apart as the yearly festival of St Thomas of Canterbury. In 1220 his bones were raised from the grave in the crypt where they had been hastily buried two days after his murder, and were deposited in a splendid shrine in the Trinity Chapel, which for three centuries continued to be the object of one of the great pilgrimages of Christendom, and which still lives in English literature in connection with Chaucer's *Canterbury Tales*. At the Reformation, Henry VIII. despoiled the shrine, erased Becket's name from the calendar, and ordered his bones to be burnt and scattered to the winds. It is difficult to estimate properly the character of Becket. We do not know what were his ultimate aims, whether, as some suppose, they were patriotic—i.e. English, as opposed to Norman, or, as others believe, purely Ultramontane. At all events, the means he used for the attainment of them was a despotic and irresponsible ecclesiasticism. He admitted nothing done by churchmen to come within the jurisdiction of civil courts, not even murder or theft. Fortunately Henry was as dogged a believer in his own powers and privileges as Becket in those of the church; and by his obstinate good sense, England was kept wholesomely jealous of the pretensions of Rome.

See Dr Giles's *Vita et Epistola S. Thomae Cantuariensis*; Canon Morris's *Life of St Thomas Becket*; Canon Robertson's *Life of Becket*; Dean Stanley's *Historical Memorials of Canterbury*; Freeman's *Historical Essays*; Hook's *Lives of the Archbishops of Canterbury*; Froude's articles on Becket in the *Nineteenth Century*.

Beckford, WILLIAM, born in Jamaica, 19th December 1709, in 1723 was sent to England, and received his education at Westminster. Elected an alderman (1752) and member for the city of London (1753), he was twice Lord Mayor. As such he showed himself a doughty Whig, a rival almost of Wilkes, a man who dared to speak face to face with a king. A petition from the corporation of London, presented by him, March 1770, to George III., being treated as unconstitutional, he, in May, presented a firm and dignified remonstrance. The

king's answer being still curt and unconciliatory, Beckford, after asking leave to speak, proceeded to argue the point with the king. His daring, or a cold, cost him his life, for just four weeks later he died in London, 21st June 1770. There is a notable statue of him in Guildhall.

Beckford, WILLIAM, son of Alderman Beckford, was born at Fonthill, Wiltshire, 1st October 1760. On his father's death in 1770 he inherited an enormous property, consisting for the main part of Fonthill and of estates in Jamaica, and estimated at a million of money, upwards of £100,000 a year. Young Beckford evinced unusual intellectual precocity; for in his seventeenth year he composed a satirical essay, entitled *Biographical Memoirs of Extraordinary Painters*, in which he did not spare living artists, and assailed the cant of criticism with the polished weapon of wit. In 1777 he visited the Continent, and met Voltaire at Paris. Three years thereafter he started on a grand continental tour, and spent twelve months in rambling through Flanders, Germany, and Italy, revisiting the last in 1782. In 1783 he married Lady Margaret Gordon, daughter of Charles, fourth Earl of Aboyne; and in the following year he entered parliament as one of the members for Wells. In 1787 *Vathek* appeared in French. Beckford informs us that he wrote this tale, as it now stands, at twenty-two years of age, and that it was composed at a single sitting. 'It took me,' he says, 'three days and two nights of hard labour. I never took off my clothes the whole time. The severe application made me very ill.' An English version of *Vathek*, made from an unpublished manuscript, had been issued in 1786. Beckford professed not to know the translator (understood to have been Samuel Henley, D.D.), but thought his work well done. In 1787 Beckford sought distraction from the loss of his young wife, a year before, in a visit to Portugal. In 1790 he sat for Hindon; in 1794 he accepted the Chiltern Hundreds, and again left England. Revisiting Portugal, he purchased an estate near Cintra, and occupied for a time that 'paradise' which Byron commemorates in *Childe Harold*. He returned to England in 1796; and in 1801 the splendid furniture of Fonthill was sold by auction, and the next year his valuable collection of pictures was disposed of in London. These dispersions were no sooner made than he began a new collection of books, pictures, furniture, curiosities, and proceeded to erect a new building at Fonthill, the most prominent feature of which was a tower 278 feet high. Beckford resided at Fonthill till 1822, when in one of those strange vagaries of feeling of which his life was so full, he sold the estate and house, with all its rare and far-gathered contents, to Colonel Farquhar for £330,000. Three years later the great tower, which had been raised on an insecure foundation, came to the ground. On the sale of Fonthill, Beckford removed to Bath, and immediately proceeded to erect another lofty tower. While residing there, he did not mingle in Bath society, and the most improbable stories concerning the rich and morose genius in their neighbourhood were circulated among the citizens. During all his life, Beckford was a hard-working student, devoured by a passion for books. Some of his purchases were perfectly imperial in their way. He bought Gibbon's library at Lausanne, to amuse himself when he happened to be in that neighbourhood. He went there; read in the fierce way that he wrote, three days and two nights at a sitting; grew weary of his purchase; and handed it over to his physician, Dr Scholl. Up till 1834 he had published nothing since *Vathek*, but in that year the literary silence of half a century was broken by the appearance of a series of letters, entitled *Italy, with Sketches of Spain and Portugal*, in two volumes. In the same year he republished

his *Memoirs of Extraordinary Painters*; and in 1835 he issued another volume, entitled *Recollections of an Excursion to the Monasteries of Alcobaça and Batalha*, made in June 1794. From the period of this last publication till his death, which took place on the 2d of May 1844, he lived in the deepest retirement. Beckford, since the publication of his Arabian tale, has been a power in English literature. His wit, his sarcasm, his power of graphic description, may be seen in his journal and letters; and his higher faculties of imaginative conception and delineation reign in the unmatched passages that shadow forth in gloom and glory the 'Hall of Eblis.' His library was sold by his great-grandson, the twelfth Duke of Hamilton, in 1882-83, when 5978 lots fetched no less a sum than £43,368. See the *Life of Beckford*, by Cyrus Redding (2 vols. 1858), the reprint of *Vathek* by M. Mallarmé (Paris, 1876), and the English edition by Garnett (1893).

Beckmann. JOHANN, was born in 1739 at Hoya, in Hanover, and was educated at Göttingen. After holding a professorship of Physics and Natural History at St Petersburg (1763-65), he was in 1766 appointed professor of Philosophy, and in 1770 of Political Economy, at Göttingen, where he died, February 4, 1811. In Germany he was the first scientific writer on agriculture. In England he is known by his *History of Inventions* (5 vols. 1780-1805; Eng. trans. 1814).

Beckwith. J. C. See WALDENSES.

Beckx. PETER JOHN, general of the Jesuits, was born at Sichein, in Belgium, February 8, 1795. He was early employed on various delicate missions, and was for many years confessor to the Duke of Anhalt-Köthen. In 1847 he was appointed procurator for the province of Austria, and on the expulsion of the society in 1848, returned to Belgium, and became rector of the college at Louvain. He was named provincial of Austria in 1852, and as head of his order from 1853, displayed an ability and tact that did much to advance the status of Jesuits in non-Catholic countries. He died at Rome, March 4, 1887.

Bequerel. ANTOINE CÉSAR, a distinguished French physicist, was born in 1788, at Châtillon-sur-Loing, in the department of Loiret. In 1808 he entered the French army as an officer of engineers, and served with distinction in Spain. On his return to France, he was appointed inspector of the *École Polytechnique*; was attached to the general staff of the army in 1814, but at the peace of 1815 retired from the service. His researches and discoveries were mainly in the fields of electricity and magnetism, and he may fairly be regarded as one of the creators of electro-chemistry. His labours in this branch of science opened to him in 1829 the doors of the Académie des Sciences. Among his works were the *Traité de l'Électricité et du Magnétisme* (7 vols. 1834-40); *Éléments d'Électrochimie* (1843); *Traité de Physique*; *Éléments de Physique terrestre et de Météorologie* (1847). He died on the 19th January 1878.—His son, ALEXANDRE EDMOND, also an eminent physicist, was born at Paris, 24th March 1820. He was decorated with the cross of the Legion of Honour in 1851; and was appointed professor of Physics in the *Conservatoire des Arts et Métiers*, in 1853. He died 13th May 1891. Besides his conjoint labours with his father, he made important researches on light, on phosphorescence, and on the conductivity and magnetic properties

of many substances. His best-known work is *La Lumière, ses Causes et ses Effets* (1868).

Beese. a town of Hungary, divided into Old and New Beese, respectively on the west and east banks of the Theiss, and 348 miles SSE. of Pesth by rail, with river fishery and a large trade in corn. Pop. 22,380.

Beeskerek. a town of Hungary, in the county of Torontal, on the Bega canal, 368 miles SSE. of Pesth by rail. Pop. 21,934.

Bective Abbey. See TRIM.

Bed, an article of furniture on which to sleep. In ancient Palestine, the bed seems to have been a simple kind of couch for reclining on during the day, and sleeping on at night, and readily removable from place to place, as is referred to in different parts of Scripture. About the heat of the day, Ishbosheth lay on his bed at noon (2 Sam. iv. 5). In receiving visitors, the king bowed himself upon the bed (1 Kings, i. 47). Jesus saith, 'Take up thy bed, and go unto thine house' (Matt. ix. 6). Yet, in these early times, beds or couches must, in some instances, have been highly ornamented: thus, 'I have decked my bed with coverings of tapestry, with carved works, with fine linen of Egypt' (Prov. vii. 16). In Persia, even at the present day, every person sleeps on a rug or piece of carpet laid on the floor, or commonly, during the summer, laid on the flat roof of a house. The pillows are similar to those used in Europe, but rather larger. It is the custom in India, on the other hand, to sleep on a bed or couch raised on four feet, called a *charpoy*. In hot climates few bed-clothes are used—there being in general only a single sheet employed; care is taken, however, to use mosquito-curtains, without which rest would be impracticable. See MOSQUITO.

Greek and Roman Beds.—Representations of ancient Greek beds and sofas are found on painted vases and on some pieces of sculpture. These beds plainly differed but little from the simpler modern forms, while the sofas or couches were in shape, in some cases at least, exactly like those now used. We are enabled to form a more perfect idea of ancient Roman beds than can be got from pictures and bas-reliefs. In the wonderful collection of Pompeian bronzes forming part of the great museum at Naples, there are three of these beds. They are partly of bronze and partly of wood, but the wooden portions, which were originally of walnut, have been restored. Fig. 1 shows one of these. It will be seen that it is of the couch form, and very

Fig. 1.—Ancient Roman Bed found at Pompeii.

elegant. Its length is 7 feet 6 in., its breadth 4 feet, and its height 1 foot 5 in. Curiously enough, an ancient trundle or truckle-bed was also found at Pompeii so recently as 1868; it is shown in the museum under one of the three larger bedsteads. The Etruscan Museum in the Vatican at Rome contains an ancient bronze bed on six feet, with a bottom

formed of strips of metal exactly like those put on brass and iron beds at the present time, only they are placed diagonally in the old example. In short, the bedsteads we now prefer are more closely like those made in Italy nearly 2000 years ago than any which have been in use during the long interval.

In Homer's time the bedding even of the richer classes consisted of a long fibred woollen blanket or mattress, and that of the poor of a simple hide spread on the hard floor. Linen sheets were used as covers. Later on, when Greece had introduced more luxurious habits from Asia, mattresses stuffed with wool or feathers became common, and of the same materials pillows were made. The Romans also stuffed their bedding with wool as well as with the soft down of geese, swans, and other birds. Their blankets and sheets were sometimes elaborately ornamented with patterns in colours either woven or embroidered.

Medieval and later Beds.—In Anglo-Saxon times, ordinary beds appear to have been plain wooden benches fixed in recesses, and having sometimes at least curtains in front—a kind of bed not yet entirely obsolete in Scotland. The bedding consisted, no doubt, of a large sack filled with straw, together with a sheet or sheets and coverlet. Mr T. Wright, in his *Homages of Other Days*, gives an illustration of a Saxon double bed of this nature with curtains. He also gives two woodcuts, after drawings in the Harleian manuscript, No. 603, of two Saxon bedsteads, box-shaped, with short corner pillars terminating in balls, and with the head end like that of a couch, but rather higher. The sides of one have thin balusters, but in the other they are plain. It is believed that these bedsteads were only used by persons of rank. The same author gives two figures of Norman beds. One of these so far resembles the isolated Saxon bedsteads, but it has a high panelled foot-board, and the sleeper lies on a slope with an oval disc at his head. The second illustration shows that the tent-bed with a top frame and side curtains was now in use. *Louandre's Les Arts Somptuaires* contains pictures of five beds, taken from a French illuminated manuscript of the 12th century. In these the bedstead takes the oblong form, with four short posts and balls, and much resembles the Anglo-Saxon ones referred to above. Except in the deep closed sides, and that in two of them the sleeper lies in a sloping position, these scarcely differ in general appearance from many plain modern beds; but at the top end there is a large flat disc, apparently swung on pivots, to enable the head to rest at any angle.

In the 13th century, beds were furnished much as at present, with a stuffed quilt, bolster, pillows, sheets, and coverlets. Among the rich, down was used; but feather-beds did not come into general use till the 15th century. All classes appear to have begun in the 13th century to take a pride in the appearance of the bed, while those who had sufficient means furnished it with handsome curtains and coverings. In the 14th century, Chaucer (*Jerme*, v. 250) describes a luxurious feather-bed with rich coverings. Illustrations of beds in the following century show that the canopy, curtains, and other parts had together the general appearance of a modern half-tester or canopied bed; but the *tester* or back and the *calure* or roof were fixed to the wall and ceiling of the room.

The large four-post bed was introduced in the 16th century, and continued in use till the middle of the 19th. Many of these beds, especially of the earlier time, were elaborately and beautifully carved, and furnished with rich hangings. Interesting examples of them are still preserved in old mansions and castles in England and on the Continent. The Great Bed of Ware, in Hertfordshire, now at Rye House, is of this age, and is one of the

curiosities of England. It is referred to in the *Twelfth Night* of Shakespeare. It measures 12 feet square (see fig. 2). A kind of camp-bed was also in use in the 16th century, which was carried about on journeys, and was frequently used in residences in place of a stationary bed. Some of

Fig. 2.—The Great Bed of Ware.

these beds were luxuriously decorated. Francis I. made a present to Henry VIII. of England of a rich camp-bed of crimson velvet, embroidered with bands of leaves in gold, and with fruit of large and small pearls, which had cost him 13,500 livres.

Modern Beds.—The heavy four-post bed, which was so long characteristic of a well-furnished English bedroom, is becoming a thing of the past. The comparatively recent and scarcely less massive half-tester bed, which suited so well for the display of the more handsome furniture-woods, has also gone out of fashion. Even the much lighter four-post tent-bed, or its later form without the curtained roof, called the French bed, that was so recently to be seen in nearly every well-to-do working-man's house in Great Britain, is fast disappearing.

For the past fifty years, bedsteads of iron and brass have been slowly gaining ground, and they are now all but universal in newly-furnished houses. Birmingham, the great British centre of light metal goods, furnishes us with some curious statistics concerning this branch of the trade. For that town and its neighbourhood, some 400 metallic bedsteads represented the weekly production in 1849. This number had increased to 5000 per week in 1865, while in 1885 the weekly output was but little short of 20,000. London, Manchester, Glasgow, and Bristol have also extensive manufacturing of these bedsteads, which are exported in large numbers to most British colonies, as well as to South America, Egypt, China, and Japan. Some are shipped to the United States, but they are now being made there in considerable quantities. Nearly all the continental nations of Europe manufacture these metallic bedsteads extensively for their own use. Beds in Germany are almost always made of a width suitable for one person only. This is largely the case in most countries of continental Europe.

An iron bedstead is very simply constructed. The strong iron bars forming the sides have simple dovetail joints at the corner pillars, which, as well as the rails for the top and bottom ends of the bed, are made of iron or brass tubing, or of both. The

exposed portions used to be decorated with painted flowers and gilding, but more usually now the ornament consists of polished surfaces, more or less relieved with brass, nickel, or silver-plated joints and mountings. The price of these varies from six shillings for a plain stump bedstead, to £50 or even £100 for a canopied bedstead with much silver-plating. An excellent bedstead of this kind can, however, be had for £8.

Alarm Bedsteads.—At the Great Exhibition of 1851 two 'Alarm Bedsteads' were exhibited. One of these was shown in operation, and caused much amusement, since it was so contrived that by the removal of a pin the foot end fell to the ground and threw the occupant on the floor. Such a bedstead has attached to it a clock with an alarm dial-plate which can be set to any hour. When the proper time comes round, the clockwork, acting upon levers and wires, causes the legs of the bedstead to be drawn from under it by means of a weight attached to the clock. It was expected that these bedsteads would be used by hotel-keepers and others for wakening servants in proper time, but very few appear to have been made.

Mattresses.—Hair and straw mattresses are too common to require any description. Covered spring mattresses filled with wire springs, held in position by chair-web, are now a good deal used. Some years ago a woven wire-spring mattress was invented in America, and of it large numbers have been made. In this, thin wire is twisted into small coils, which are interlocked by a process known as double weaving. About 8000 feet of wire are required to make one of these of ordinary size. It is considered soft and comfortable, and has been found serviceable in cases of protracted sickness (see also AIR-BEDS and WATER-BEDS). Stronger spring mattresses, which are really spring and chain mattresses, one kind of which is called 'the Excelsior,' are also coming much into use. These spring mattresses are usually covered with another thin mattress stuffed with hair or wool, feather-beds being now rarely used.

Mats and Pillows in Warm Countries.—In most parts of Africa, and the tropical and subtropical islands of the Pacific Ocean, it is a common custom

from the roofs of tents or from trees. At least one form of the ancient Egyptian bedstead appears to have been like the one still common in that country, namely, a low frame formed of wicker-work of palm-sticks. Much more curious, however, is the pillow used in Egypt in ancient times, since it forms the type of many used at the present time in far-distant countries. These Egyptian pillows or head-rests were generally made of wood, but sometimes of alabaster or earthenware. Fig. 3, c, represents one of wood, from the Tombs of Thebes. The same kind of wooden pillow or support for the head is still found in Abyssinia, the delta of the Zambesi, and in that direction as far south as Swaziland. It is also used in the country around Lake Tanganyika, in Ashanti, and in other parts of Africa. Much the same form of head-rest is made in the Fiji Islands, in Tahiti, and in New Guinea; while in China and Japan we find a somewhat similar pillow of wood, lacquered it may be, with a small cylindrical cushion on the top. The preceding figures show several of these pillows.

In geology, *bed* is synonymous, or nearly so, with STRATUM (q.v.); and see GEOLOGY, also the articles BALA BEDS, BEMBRIDGE BEDS, MAESTRICHT BEDS, PURBECK, EOCENE, &c.

Bed-sores are the subject of a separate article (see p. 16); and *Bed of Justice* is dealt with also on page 16 below.

Bédarioux, a town of France, department of Hérault, situated on the river Orb, 27 miles NNW. of Béziers by rail. It is neat and well built, with manufactures of cloths and woollen goods, hats, paper, leather, and oils. There are glass-works and a copper-foundry at Clairac, in the neighbourhood. Pop. 6046.

Bedchamber. LORDS OF THE, officers in the British royal household, twelve in number, who, in the reign of a king, wait in turn upon the sovereign's person. They are under the groom of the stole, who attends his majesty only on state occasions. There are also thirteen grooms of the bedchamber, who take their turns of attendance. The salary of the groom of the stole is £2000; of the lords of the bedchamber, £1000; and of the grooms, £500 a year. These offices in the reign of a queen are performed by ladies. Corresponding to the groom of the stole is the mistress of the robes, and to the grooms of the bedchamber are bedchamber women. These offices are objects of high ambition, from the access they give to the person of the sovereign, and are for the most part filled by 'the prime nobility of England.' In 1839 the queen's refusal to part with the ladies of her bedchamber, on the occasion of a change of government, led to Sir Robert Peel's declining to form a ministry, and to Lord Melbourne's return to office. The incident was playfully called 'The Bedchamber Plot.' See HOUSEHOLD (THE KING'S OR QUEEN'S), and Mrs Armytage, *Old Court Customs and Modern Court Rule* (1883).

Beddgelert ('grave of Gelert'), a Carnarvonshire village, which is a great tourist centre, near Aberglaslyn Pass, 12 miles SE. of Carnarvon. The grave of the legendary hound of Llewellyn (see GELLERT) is marked by a few stones. The ascent of Snowdon is often made from this 'gem of Welsh villages,' which is the principal scene of Southey's *Madoe*.

Beddoe, JOHN, anthropologist, born at Bewdley, Worcestershire, in 1826, was educated at Bridgnorth, University College, London, and Edinburgh University, graduating B.A. of London in 1851, and M.D. of Edinburgh in 1853. He served as a civil surgeon during the Crimean war, and afterwards established himself in practice at Clifton. He is the author of *Stature and Bulk of Man in the*

Fig. 3.—Various forms of Pillows:

to sleep on mats of some vegetable fibre, but sometimes skins are used for this purpose. Many South American Indians sleep on hammocks suspended

British Isles (1870), *The Races of Britain* (1886), and other anthropological and ethnological works.

Beddoes, THOMAS, physician, born at Shifnal, Shropshire, in 1760, passed from Bridgnorth grammar-school to Pembroke College, Oxford, and afterwards studied medicine at Edinburgh and London. In 1788, after taking his M.D. at Oxford, he was appointed reader in chemistry there, but his sympathies with the French Revolution rendered his post so uncomfortable that he resigned it in 1792, and retiring into the country, wrote his work *On the Nature of Demonstrative Evidence*. Several patriotic pamphlets followed, and the *History of Isaac Jenkins*, in which he laid down, in a popular style, rules of sobriety, health, &c. for the working-classes. Of this work 40,000 copies were sold in a short time. He married Anna, sister of Maria Edgeworth. In 1798, after careful study of the use of artificial or medicated gases in the cure of diseases, especially consumption, aided by his father-in-law, Mr Edgeworth, and peculiarly assisted by his friend, Thomas Wedgwood, he opened a 'pneumatic' hospital at Clifton. It did not succeed in its main object, which was to show that all diseases being referable to an undue proportion or deficiency of some elementary principle in the human organism, could be cured by breathing a medicated atmosphere; and Beddoes, whose zeal had abated, retired from it in 1801. He died 24th December 1808. The chief result of Beddoes' enterprise was the introduction to the world of Sir Humphry Davy, who was the superintendent of the institution, and who says of Beddoes: 'He had talents which would have exalted him to the pinnacle of philosophical eminence, if they had been applied with discretion;' and Southey wrote on hearing of his death: 'From Beddoes I hoped for more good to the human race than any other individual.' See the Life of Beddoes by Dr Stock (1811).

Beddoes, THOMAS LOVELL, eldest son of the above, and nephew of Maria Edgeworth, was born at Clifton, 20th July 1803. From Bath grammar-school he passed in 1817 to the Charterhouse, and thence in 1820 to Pembroke College, Oxford. In 1822 he published *The Bride's Tragedy*, which achieved a brilliant success. In 1825 he went to Göttingen to study medicine, and thenceforth led a strange wandering life as doctor and democrat, in Germany and Switzerland, with occasional visits to England. From 1825 he was engaged in the composition of a drama, *Death's Jest-book*, which, with his poems and a memoir by Kelsall, appeared in 1850-51. The story of his death by suicide at Basel (26th January 1849) was told for the first time in Mr Gosse's memoir prefixed to his edition of the *Poetical Works* (2 vols. 1890). The poems of Beddoes, almost all nominally dramatic, exhibit no power of characterisation, no ability in the conduct of a story; but the fullness of thought and image, the tone of music, and the depth of colour are marvellous.

Bede, or BEDA, the VENERABLE, the greatest name in the ancient literature of England, was born in the neighbourhood of Monkwearmouth, in the county of Durham, about the year 673 A.D. He was educated under the care of the learned and liberal abbot, Benedict Biscop, and his successor, Ceolfrid, in the Benedictine abbey at Monkwearmouth, to which the young scholar came an orphan child in his seventh year. Ultimately he entered the monastery at Jarrow, an offshoot of the same foundation, and here he remained until his death. Here he took deacon's orders in his nineteenth year, and was ordained priest in his thirtieth, by John of Beverley, then Bishop of Hexham. In the shelter of his quiet and sacred retreat he devoted

himself to study, while he was diligent in observing the discipline of his order, as well as in the daily service of the monastery church. His industry was enormous, and he was continually employed in reading, writing, and teaching. Besides Latin and Greek, classical as well as patristic literature, he studied Hebrew, medicine, astronomy, and prosody. He wrote homilies, lives of saints, hymns, epigrams, works on chronology and grammar, and commentaries on the books of the Old and New Testament. His calm and gentle spirit, the humanising character of his pursuits, and the holiness of his life, present a striking contrast to the turbulent temper of his time. When labouring under disease, and near the close of his life, he engaged in a translation of St John's Gospel into Anglo-Saxon, and dictated his version to his pupils. The well-known story of how he finished the last sentence of his version on the very day of his death casts a light on the serene and simple piety of his life. His brethren had all gone to the festival, and he was left alone with the scribe. 'Dearest master,' said the latter, 'there is one chapter wanting, and it is hard for thee to question thyself.' 'No, it is easy,' said he; 'take thy pen and write quickly.' When evening came, the young scribe said, 'There is yet one more sentence, dear master, to write out.' He answered, 'Write quickly.' Shortly after the boy said, 'Now it is finished.' 'Well,' said the aged saint, 'thou hast spoken truly "it is finished."' Then he bade them place him where he could look on the spot on which he was wont to kneel in prayer. Then he chanted the *Gloria Patri*, and as he uttered the words 'the Holy Ghost,' he breathed his last, and 'so passed to the kingdom in heaven,' on the day of the Feast of the Ascension, 26th May 735. He was buried in the monastery of Jarrow: long afterwards (in the middle of the 11th century) his bones were removed to Durham. His most valuable work is the *Historia Ecclesiastica Gentis Anglorum*, an ecclesiastical history of England, in five books, to which we are indebted for almost all our information on the ancient history of England down to 731 A.D. Bede gained the materials for this work partly from Roman writers, but chiefly from native chronicles and biographies, records and public documents, and oral and written communications from his contemporaries. King Alfred translated it into Anglo-Saxon. At the close of his great work he gives the names of the thirty-seven books which he had written up to 731. His *De Sex Aetatibus Mundi* was an important book in chronology. 'First,' says Green, 'among English scholars, first among English theologians, first among English historians, it is in the monk of Jarrow that English literature strikes its roots. In the six hundred scholars who gathered round him for instruction, he is the father of our national education.' Among the editions of Bede's History may be noticed: the first, supposed to have been printed at Strasburg about 1473, others, more correct, at the same place, in 1483 and in 1500; a much better edition, by Canon J. Smith (Cambridge, 1722); one not less valuable, by J. Stevenson (2 vols. Lond. 1838); another, by the late Dr Hussey (Oxford, 1846); that by G. H. Moberley at the Clarendon Press (1869); and that by Holder (Freiburg, 1882). Editions of his complete works have been published in Paris (6 vols. folio. 1544-45), Basel (8 vols. folio. 1563), Cologne (1612 and 1688), at London in 12 vols. by Dr Giles (1843-44), and at Paris by J. P. Migne as vols. xc.-xev. in the *Patrologia Cursus Completus* (1844). English versions of the *Ecclesiastical History* were published by Stapleton in 1655; by Stevens in 1723; by Hurst in 1814; by Dr Giles in 1840; and by L. Gidley (1870). See also H. H. Hanson's *Essays on Bede's Ecclesiastical History* (1888).

Bedeau, MARIE ALPHONSE, a French general, born near Nantes in 1804, entered the army in 1825. Sent in 1836 to Algeria, as commandant of a battalion he took part in most of the military operations, and in 1847 was for three months governor of Algeria. In 1848 he was commissioned by Marshal Bugeaud to suppress the February revolution in Paris, but failed. He took office under the Provisional Government, and was named vice-president of the Constituent Assembly, always voting with the Republican party. Along with Cavaignac and Lamoricière he was arrested in December 1851, and went into exile; he died at Nantes, 30th October 1863.

Bedeguar (Persian and Arabic *bādāwar*, literally 'wind-brought'; sometimes explained as made up of Persian *bād*, 'wind,' and Arabic *ward*, 'rose'), a remarkable Gall (q.v.) of roundish shape, but covered with shaggy branched processes, like those familiar in the moss-rose, often found on the branches of various species of rose, particularly of the sweet-brier, upon which account it is sometimes called sweet-brier sponge. Although of course sharing the astringent properties of galls in general, it has long ceased to be of any medicinal repute.

Bedell, WILLIAM, Bishop, born at Black Notley, Essex, in 1571, was educated at Emmanuel College, Cambridge. From 1602 to 1613 he was incumbent of St Mary's at Bury St Edmunds, save that during 1607-11 he was chaplain to Sir Henry Wotton, the British ambassador to Venice, where he made the friendship of Father Paul Sarpi. In 1616 he retired to the neighbouring parish of Horningsheath, whence in 1627 he was called to become provost of Trinity College, Dublin. Two years afterwards he was promoted to the united bishoprics of Kilmore and Ardagh, the latter of which he resigned in 1633. He immediately set himself to reform the crying abuses that prevailed in his diocese, and with so happy a combination of wisdom, firmness, and charity, that even his enemies were constrained to do homage to his virtues. The translation of the Old Testament into Irish was accomplished under Bedell's direction (the New had been already translated). On the breaking out of the rebellion in 1641, his popularity for some time saved his family from violence, his being the only English house in County Cavan that was spared. At length he was seized and imprisoned in Loughoughter Castle. He was soon allowed to remove to the house of a Protestant clergyman at Drumlor, but there catching a fever, he died 7th February 1642. See the *Life* by his son, edited by T. W. Jones for the Camden Society (1872).

Bedford, the county town of Bedfordshire, is situated on the navigable Ouse, 49 miles NNW. of London by rail, and in the midst of a broad expanse of rich pasture and corn lands. The Ouse is spanned here by two bridges—a stone one of five arches, 306 feet long, built in 1811 at a cost of £15,000, and an iron one, built in 1888 at a cost of £6000. Bedford itself is clean and well paved, and the drainage and water-supply have been greatly improved. The charitable and educational institutions are mostly due to Sir W. Harpur, Lord Mayor of London (d. 1574). He in 1566 founded a free school, and endowed it with 13 acres of land in Holborn. The enormously increased value of the property (from £150 to £15,000 a year) enables the trustees to maintain grammar, modern, and preparatory schools for boys, the same class of schools for girls, and almshouses. Under the scheme (1874) of the Endowed School Commissioners, the funds are divided thus: One-eleventh to the almshouses; two-elevenths to elementary education;

four-elevenths to the grammar-school and high-school for girls; and four-elevenths to the modern schools. The county school was opened in 1869. The chief manufacture is that of agricultural implements. Lace-making is also carried on; straw-plaiting has declined. An embankment beside the Ouse forms a pretty promenade; and a people's park of 60 acres was opened in 1888. Bedford returns one member (till 1885 two) to parliament. Pop. (1851) 12,693; (1891) 28,023. Bedford is of great antiquity, and is mentioned in the *Anglo-Saxon Chronicle* under the name of Bedican-fortha, as the scene of a battle between the Britons and Saxons in 571. The Danes burnt it in 1010. Afterwards its old castle, said to have been built by Edward the Elder, is frequently mentioned in history. Bunyan (q.v.), who was born at Elstow, near Bedford, was for twelve years a prisoner in Bedford gaol, and ministered to the Nonconformist congregation in Mill Lane from 1672 to his death in 1688. His chapel has been twice rebuilt, in 1707 and 1849; but his chair and other relics of him are preserved; whilst a colossal bronze statue of him by Boehm was erected at the cost of the Duke of Bedford in 1874. New buildings for the grammar-school were opened in 1891, and the recreation-ground of 22 acres gifted by the Duke of Bedford in 1894. In 1894 a bronze statue of John Howard (q.v.) was erected.

Bedford College. See WOMEN'S RIGHTS.

Bedford, JOHN, DUKE OF, third son of Henry IV., was born about 1389. During his father's lifetime he was governor of Berwick-upon-Tweed, and warden of the Scottish marches. In 1415 his brother, Henry V., created him Duke of Bedford; and during the war with France he was left in command of the forces in England. After Henry's death (1422), Bedford went to France to look after the interests of the infant prince, his nephew. The regency of France he offered to the Duke of Burgundy, who refused it; he then assumed it himself. On the death of Charles, a few months after Henry V., Bedford had his nephew proclaimed king of France and England, as Henry VI. In the wars with the dauphin which followed, Bedford displayed great generalship, and defeated the French in several battles—most disastrously at Verneuil in 1424. But, in consequence of the rather parsimonious way in which men and money were doled out to him from England, and the withdrawal of the forces of the Duke of Burgundy, he was unable to take full advantage of his victories. The appearance of Joan of Arc, notwithstanding his utmost energy, was followed by disaster to the English arms; and in 1435 a treaty of peace was negotiated at Rouen between Charles VII. and the Duke of Burgundy, which effectually ruined English interests in France. The death of Bedford, which took place September 19, 1435, fourteen days before the ratification of that treaty, was mainly, if not altogether, occasioned by his anxiety and vexation on account of the union thus formed. Bedford, who was a patron of letters, purchased and removed to London the Royal Library of Paris, consisting of 900 volumes. For the present dukedom of Bedford, see RUSSELL.

Bedford Level, an extensive tract of flat land in the east of England, embracing nearly all the marshy district called the Fens. It extends inland around the Wash into the six counties of Northampton, Huntingdon, Cambridge, Lincoln, Norfolk, and Suffolk, and has an area of about 750,000 acres. Its inland boundary forms a horseshoe of high lands, and reaches the towns or villages of Brandon, Milton (near Cambridge), Earith, Peterborough, and Bolingbroke. It is divided into three parts—the north level, between

the rivers Welland and Nene; the middle, between the Nene and the Old Bedford River; and the south, extending to Stoke, Feltwell, and Mildenhall. It is intersected by many artificial channels, as well as by the lower parts of the rivers Nene, Cam, Ouse (Great and Little), Welland, Glen, Lark, and Stoke. It receives the waters of the whole or parts of nine counties. This district seems to have been a great forest at the time of the Romans, who cut the forest down, formed great embankments to exclude the tide, and rendered the tract for a time a fertile inhabited region. In the 13th century, violent incursions of the sea stopped the outflow of the rivers, and it became a morass. The practicability of draining this extensive region seems to have been thought of as early as 1436, and many partial attempts were made after this. The first effectual effort was in 1634, when Francis, Earl of Bedford, after whom the district was thenceforth called, obtained, along with thirteen others, a grant of 95,000 acres of the reclaimed land on condition of draining the level. The work was partially accomplished in three years, at a cost of £100,000; but was pronounced inadequate by government. Charles I. tried to get the work, with a greatly increased premium, into his own hands; but the civil war stopped further progress. In 1649 parliament confirmed William, Earl of Bedford, in the rights granted to his father; and after a fresh outlay of £300,000, the contract was fulfilled. In 1688 a corporation was formed for the management of the level. The middle level has always been the most difficult to manage; and the work on it, with one drain 11 miles long, was only completed in 1852 at a cost of £400,000. The St Germain's sluice, at the confluence of that drain with the Ouse, was considered perfectly secure. But in May 1862 it gave way under the pressure of a strong tide, and the western bank of the middle-level drain burst, speedily flooding about 6000 acres of fertile land. This led to the construction of a permanent cofferdam of pile-work to shut off the tidal waters; and for the drainage of the middle level, Slater's-Lode sluice was taken advantage of: siphon pipes being laid over the cofferdam, the flood-waters let off by them and by drains, the siphons acting as permanent sluice.

See Heathcote's *Reminiscences of Fox and Merc* (1876); the Duke of Bedford's *Great Agricultural Estate* (1897).

Bedfordshire, a midland county of England, surrounded by Huntingdon, Cambridgeshire, Herts, Bucks, and Northamptonshire. It stands 37th of the 40 English counties in size, and 36th in population. Extreme length, 31 miles; breadth, 25; area, 461 sq. m. The general surface is level, with gentle undulations. In the south, a range of chalk-hills, branching from the Chilterns, crosses Bedfordshire in a north-east direction from Dunstable, and another parallel range runs from Ampthill to near the junction of the Ivel with the Ouse. Between the latter ridge and the north-west part of the county, where the land is also somewhat hilly, lies the corn vale of Bedford. No hill in Bedfordshire much exceeds 500 feet in height. The chief rivers are the Ouse (running through the centre of the county, 17 miles in a direct line, but 45 by its windings), navigable to Bedford; and its tributary, the Ivel, navigable to Shefford. By these rivers Bedfordshire communicates with the counties of Cambridge, Huntingdon, and Norfolk. The south and south-east parts of the county consist of chalk, and the north and north-west of oolitic strata. Freestone is quarried, as well as chalk or clunch, to be burnt for lime. The soil varies greatly. In the south of the county it is chalk thinly covered with earth, and fit only for sheep-walks; but three-fourths of the county is

clay, which is very stiff between the Ivel and Ouse. A rich gravelly loam exists along the rivers. In the vale of Bedford the soil is chiefly rich clay and deep loam; and to the north the clay is stiff, poor, and wet. There are extensive market-gardens, especially on the rich deep loams. Bedfordshire is the most exclusively agricultural county in England, its cultivated area being 88.1 per cent., against 79.3 for the whole kingdom. Pop. (1801) 63,393; (1881) 149,473; (1891) 160,709. The principal proprietor is the Duke of Bedford; and his seat, Woburn Abbey, is the chief mansion. Lace-making and straw-plaiting—for which Dunstable is celebrated—are leading industries, and they are carried on almost entirely by women. Bedfordshire is divided into nine hundreds and 122 parishes. Two members of parliament are returned for the county of Bedfordshire, one for the Biggleswade, and one for the Luton division. Many British and Roman antiquities exist in the county, as well as the ruins of several monasteries, and some fine relics of Romanesque and Gothic architecture among the parish churches. Three Roman roads crossed the county, and several earthwork camps remain.

Bedlam (now officially written *Bethlem*), the London lunatic asylum, originally founded in 1247 as a priory at Bishopsgate, its mother-church being St Mary's of Bethlehem (or Bedleem in Wyclif's spelling). It is spoken of as a hospital for lunatics in 1472, and as such it was granted at the dissolution to the mayor and citizens of London, being incorporated as a royal foundation in 1547. In 1676 it was transferred to Moorfields, and in 1815 to St George's Fields, Lambeth. This the present hospital was extended in 1838; but when Broadmoor was built in 1863, the criminal wings were pulled down, so that it now accommodates 300 patients. In the old Moorfields days, the management of Bedlam was deplorable. The patients were exhibited to the public, like wild beasts, as we see in Hogarth's picture, and read in Pejys and Boswell; whilst partial convalescents, with badges on their arms, were turned out to wander and beg in the streets. Edgar, in *King Lear*, personates one of these 'Tom-o-Bedlams.' This practice, however, would seem to have been stopped by 1675.

Bedlington Terrier, a breed originated about the beginning of the 19th century by Mr Aynsley of Bedlington, near Morpeth, in Northumberland, to which county it was almost entirely confined for many years. Its chief points are the following: Muzzle, long and fine, but very powerful; head, high in the skull and rather narrow, the hair on the top being softer and of a lighter colour than on the rest of the body; eyes, small, dark, and slightly sunk; ears, rather large and filbert-shaped, hanging close to the cheeks, and slightly feathered; neck, long, slender, but muscular; body, well proportioned, and deep chested, though rather lightly ribbed; legs, straight and somewhat long; tail, of moderate length, tapering to a point, with no feather; coat, fine but not soft, short and rather thin; colour, liver or sandy, with flesh-coloured nose, or blue-black, with black nose, the latter being the commoner colour; weight, from 16 to 20 lb.; height, 13 inches. The Bedlington terrier is remarkably high couraged, and makes a splendid vermin dog, on account of its activity and pluck, and will face even an otter or badger without flinching. It also makes a capital water-dog, and may be broken to the gun, for which purpose its speed and cleverness make it highly useful.

Bedmar, ALFONSO DE CUEVA, MARQUIS DE, born in 1572, won an enduring notoriety on account

of his daring and unscrupulous plot for the destruction of Venice, to which city he had been appointed ambassador from the court of Spain in 1607. He first leagued himself secretly with the Duke of Ossuna, viceroy of Naples, and Don Pedro of Toledo, governor of Milan, then purchased the services of a large number of foreign mercenaries, while Ossuna furnished him with a band of privateers, or rather pirates. The day chosen for carrying out his purpose was that on which the doge wedded the Adriatic, when all Venice was intent on beholding the august ceremony. Fortunately, the night before, one of the conspirators betrayed the plot. Several persons were executed; but curiously enough, Bedmar, the arch-delinquent, was only dismissed. The event forms the subject of Otway's *Venice Preserved*. Bedmar now went to Flanders, where he became president of the council, and in 1622 was made a cardinal by the pope. He then went to Rome, and finally returned to Spain as Bishop of Oviedo, where he died in 1655.

Bednor'. BEDNUR, or NAGAR, a decayed city, now a village, of Mysore, India, situated in the midst of a basin in a rugged tableland of the Western Ghats, at an elevation of more than 4000 feet above the sea, 150 miles NW. of Seringapatam. It was at one time the seat of government of a rajah, and its pop. exceeded 100,000. In 1763 it was taken by Hyder Ali, who pillaged it of property to the estimated value of £12,000,000, and subsequently established an arsenal here.

Bed of Justice (Fr. *lit de justice*), literally, the seat or throne occupied by the French monarch when he was present at the deliberations of parliament. Historically, a bed of justice signified a solemn session, in which the king was present to overrule the decisions of parliament, and to enforce the acceptance of edicts or ordinances which it had previously rejected. The theory of the old French constitution was that the authority of parliament was derived solely from the crown; consequently, when the king, the source of authority, was present, that which was delegated ceased. Acknowledging such a principle, the parliament was logically incapable of resisting any demand that the king in a bed of justice might make, and decrees promulgated during a sitting of this kind were held to be of more authority than ordinary decisions of parliament. Monarchs were not slow to take advantage of this power to overawe any parliament that exhibited signs of independence. The last bed of justice was held by Louis XVI. at Versailles in September 1787, when the whole parliament were arrested and confined in prisons in different parts of France.

Bedos de Celles, DOM FRANÇOIS, a Benedictine monk of the congregation of St Maur, and the most learned and practical master of the art of organ-building in the 18th century. He was born at Caux in 1706, and entered his order in 1726 at Toulouse. He was elected a member of the Academy of Sciences in 1758; in 1766-78 was published for the academy his great work, *L'Art du Facteur d'Orgues*, in 4 vols. large folio, with 137 copperplates, beautifully executed. He died in 1779.

Bed'ouins (Arab. *Bedāwi*, 'dwellers in the desert') are Arabs who lead a nomadic life. The most ancient notices found in Scripture agree, in their descriptions of the manners and customs of the Bedouins, with the facts of the present time. As nomads, the Bedouin Arabs have no united history, but only a collection of genealogies. They have but seldom appeared as a united people taking a prominent part in the world's politics, and have never been entirely held in subjection by any

foreign power. The desert of Arabia is their central place of abode; but even in ancient times they had spread themselves over the deserts of Egypt and Syria; and in later times they entered Mesopotamia and Chaldea. The conquest of Northern Africa in the 7th century opened up to them still vaster tracts. At present they are to be found from the western boundary of Persia to the Atlantic, and from the mountains of Kurdistan to the negro countries of Soudan. In the cultivated lands of Mesopotamia, Chaldea, the Syrian confines, Barbary, Nubia, and the north of Soudan, the Arabs are found intermingled with other nations; but in the deserts they have maintained their distinct character and independence. They form a seventh part of the population of Arabia. The characteristics of the Bedouins, as herdsmen and robbers in the desert, are intimately connected with the nature of their habitation. Their abstinent, precarious, and often solitary mode of life makes them disposed to exercise mutual hospitality; but their independence, love of liberty, and other good qualities, are associated with violent passions and an infamous love of plunder, reckless of the rights of property. They are lean, sinewy, and active, but commonly below middle stature. Their senses, especially sight, are keen; the nose is commonly aquiline; in complexion they are of various shades of brown. With the exception of certain tribes in Syria, all the Bedouins are professedly Mohammedans, but are as much Sabeans, and have, beyond a belief in one God, extremely little religion. Clergy are unknown, except where dread of the Wahabis extends. Though the Bedouin's intellectual powers are naturally good, they are miserably destitute of solid knowledge. Their endless tales and poetical effusions show a wonderful activity of imagination and an oriental love of hyperbole. The relation of the sexes to each other is less constrained than among the settled peoples of the East. Bigamy is rare, polygamy scarcely known; divorce of the wife is extremely common and easy. Their diet is principally derived from their herds, but includes rice, a few vegetables, honey, locusts, and even lizards. They manufacture their own woollen clothing. Many tribes shave the head; but among all the beard is a favourite object of cultivation. The political condition of the Bedouin is patriarchal. One or more families form the core of a tribe, and constitute a kind of aristocracy. Out of their number the superior *sheikh* is elected, who leads those of the tribe that choose to follow, and the *kādī*, who judges between such litigants as accept his award. But custom is law, and each tribesman is his own executive. This sketch of the Bedouin applies chiefly to the true nomads, or 'dwellers in the desert,' and is subject to modifications with regard to tribes in Barbary, Syria, and Mesopotamia, who practise agriculture, and dwell in houses.

Bed-sores are often a very troublesome complication of disease, to which a patient is liable when, confined for a long time to bed, he is either unable or is not allowed to change his position. They attack the skin over bony prominences, especially the lower parts of the spine, the haunch bones, the heel, and the elbow. The skin becomes red at first, and its surface is gradually abraded; this may end in the death of a portion of the skin, which separates as a *slough*, and a deep ulcer appears beneath it. General debility, the continued fevers (especially typhoid), paralysis, and old age, are strong predisposing causes. The immediate causes are continuous pressure on the affected parts and a lack of care in nursing; as, for instance, incomplete cleanliness, where the evacuations escape involuntarily, and where

the undersheet is not kept smooth and free from irritating particles. The patient sometimes complains of a sense of discomfort at the parts, as if he were lying on dry crumbs of bread; at other times, he seems to feel nothing. Hence, in all cases of prolonged confinement to bed, the parts naturally pressed upon by the weight of the body should be carefully examined every day or two, as prevention is far easier than cure. When a long confinement to bed is expected, attempts should be made to thicken the cuticle, and enable it to bear pressure better, by rubbing the skin with a stimulant such as spirits or eau-de-Cologne. If the part, when first seen, looks red and rough, further damage is often prevented by covering it with a piece of calico, on which soap-plaster has been spread; the local pressure may be removed by air-cushions specially constructed for cases of this kind, and in many instances Arnott's Water-bed (q.v.) affords great comfort. If the case is one in which it is admissible, the patient should be made to alter his position frequently. Should an abrasion form, it must be painted over with a layer of collodion, which forms a protective covering to the part; at this stage, also, all pressure must be removed from the part if possible. When the dusky colour of an insulated piece of skin shows that a *slough* is forming, a water-dressing must be applied and renewed every eight hours. It consists of four layers of borie lint cut a little larger than the size of the livid portion of skin. The lint, wrung out of hot water, is covered by a piece of oiled silk that overlaps it for half an inch in every direction. When the slough separates, a similar dressing should be continued for the ulcer, on the surface of which a little iodoform is sprinkled before the water-dressing is applied. In severe cases, where there is enlargement of the sores, or increased discharge from them, a 'prone conch' should be used, on which the patient lies on his face. This gives great relief, and allows healing to take place.

Bedstraw (*Galium*), a genus of Rubiaceæ (q.v.). The species are very numerous, natives chiefly of the colder parts of the northern hemisphere, or of mountainous regions within or near

Rennet, because it has the property of curdling milk, and has been long used for that purpose (whence the generic name from Gr. *gála*, 'milk')—a small plant with linear deflexed leaves and dense panicles of bright yellow flowers, very abundant on dry banks. The flowering tops, boiled in alum, furnish the Icelanders with a bright yellow dye; while the Highlanders used to employ the root-stock for dyeing yarn red. Their colour being essentially that of the allied madder, the cultivation of the plant was attempted many years ago. Certain North American species, especially *G. tinctorium* and *G. septentrionale*, have been used in the same way. Like madder, they possess the property of imparting a red colour to the bones and milk of animals which feed upon them. Medicinal virtues were ascribed to some of the species, as *G. rigidum* and *G. mollugo*. The roasted seeds of some, as *G. aparine*, the troublesome Goosegrass, or Cleavers, of our hedges—remarkable for the hooked prickles of its stem, leaves, and fruit—have been recommended as a substitute for coffee; but it does not appear that they contain any principle analogous to caffeine. Its expressed juice is in some countries a popular remedy for cutaneous disorders, and is used as a safe and efficient diuretic. The roots of *G. tuberosum* are farinaceous, and it is cultivated in China for food. The name *bedstraw* is due to the old legendary name of one of the species, 'Our Lady's Bedstraw,' analogous to 'Our Lady's Garters, Mantle, Slippers,' &c.

Bedworth, a market-town of Warwickshire, 3 miles S. of Nuneaton. Pop. of parish, 5485.

Bee. Bees form a family of insects belonging to the order Hymenoptera, and to the same sub-order as the wasps and ants. Like other Hymenoptera, they possess four membranous naked wings with well-developed nervures, and mouth organs, in part at least, adapted for biting. The head is freely attached to the middle part of the body—the thorax, and the first ring of the latter (the prothorax) is much reduced. The life-history exhibits a complete metamorphosis. In the special sub-order to which bees belong (Aculeata), the imperfect females (workers) have a poisonous sting at the posterior end of the body, and their feelers or antennæ have twelve joints, one fewer than in the males. The posterior part of the body—the abdomen—is distinctly stalked; the legs and mouth-parts are modified in relation to their diet of nectar and pollen. The larvae are footless grubs, and are usually hatched in special cells. A high degree of social life and intelligence is very frequent.

History.—Bees must have been among the first insects to engage human attention. Their comparatively large size, abundant occurrence, social life, and honey-storing habits appear to have been from very early times facts of common observation. Aristotle has gathered up some of the opinions of his contemporaries in regard to bees—opinions, however, in which much fancy is mingled with some acute observations. Virgil has described the habits of bees in his fourth Georgic with all the license of a poet and the enthusiasm of a lover of nature. Pliny repeats, as he was wont, all the floating bee-gossip of his time, but without criticism or analysis. For about fourteen centuries after Pliny, bees were unmolested by the naturalist, and were, as far as we know, only thought of as the sources of occasional luxury. With the Renaissance, however, the natural history of bees became again the subject of study. Works by Edward Wotton and Conrad Gesner contain numerous trustworthy observations, and were the preface to a series of careful studies by

A, Common Great Bedstraw (*Galium latum*);
B, Yellow Bedstraw (*Galium verum*).
a, flower; b, fruit.

the tropics. About eleven species are found in Britain, some of them very common weeds. Amongst these is the Ladies' Bedstraw, or Yellow Bedstraw (*G. verum*)—sometimes called Cheese

various naturalists in the latter half of the 17th century. Conspicuous among these are the works of Swammerdam (*General History of Insects*, 1669); the memoirs of Maraldi (1712), who is said to have been the first to use glass-hives; and the clear observations of John Ray and his friend Willughby. On a higher plane of detailed anatomical research stands the immortal work of Réaumur (*Mémoires pour servir à l'Histoire des Insectes*, 1732-44), from which the systematic and thoroughly scientific study of bees may be said to date. His contemporary Bonnet also was the author of numerous important observations; while among the crowd of naturalists who have worthily continued the researches of Réaumur, the patient and ingenious Hübner is undoubtedly pre-eminent (*Nouvelles Observations sur les Abeilles*, 1814). The more modern experimental method of investigation is well represented by Sir J. Lubbock's researches (see *Ants, Bees, and Wasps*).

Form and Structure.—Before noting the more important features in the anatomy of the bee, it is necessary to recall the familiar fact that many kinds of bees are social, that is to say that they live in communities. The following observations apply to the live-bee. As in the case of ants, various sets of members have come to discharge special functions, and the result of this division of labour has been difference of form, or polymorphism. In fact, the result of restricted function has been the establishment of castes. Thus the ordinary hive contains (1) a single queen-bee—the fertile female and mother of the next brood, (2) the males or drones, and (3) the vast majority of workers or imperfectly developed females, which only exceptionally become fertile. In describing the anatomy, the ordinary hive-bee (*Apis mellifica*, L.) will be principally referred to. Like that of other insects, the body of the bee is readily divisible into three portions—head, thorax, and abdomen. The *head* is well defined from the body, and bears the organs of sight, touch, mastication, and honey-collecting. There are two compound *eyes*, borne on the sides of the head. They are largest in the males, and meet on the crown. Besides these there are, on the top of the head, three *eye-spots* or ocelli, concerning the exact function of which there is some difference of opinion. Below the eyes are (1) two jointed feelers or antennæ, most essential organs of sensation. The basal joint is much the largest, and the stalk formed from the eleven or twelve smaller ones extends outwards at a sort of knee-like angle (geniculate). In the antennæ of the males there are thirteen joints; in those of the females, twelve. (2) Next come the horny, toothed mandibles, freely articulated to the head, and well adapted for cutting the resinous cement or propolis into shapes, for the finer work of handling the pollen, for biting through the corollas and other obstructions of flowers, and the like. The other two pairs of head appendages are greatly modified for collecting the nectar from the flowers. (3) The *first pair of maxillæ* are much elongated flattened blades, embracing the second pair, and forming the outer sheath of the proboscis, as the entire collecting organ is called. They form the outer wall of a sort of suction-tube. The tips of these blades, however, remain sharp, and act as efficient piercing organs. The external portions of this first pair of maxillæ, the so-called maxillary palps, degenerate, and only remain as much-reduced structures with a few joints. (4) The fused basal portion of the *second pair of maxillæ*, the *mentum*, as it is called, is in movable membranous and elastic connection with the cardines or bases of the first pair.

This mentum bears internally the long structure known as the *ligula* or *tongue*. This is a much

elongated slender hairy organ of varying firmness throughout its course. It occupies a number of very different positions according to the business of the bee at the moment, but a description of these would involve inconvenient detail. The four main positions are very lucidly depicted in Hermann Müller's *Fertilisation of Flowers*. When at rest, the internal portion of the tongue is somewhat

Fig. 1.—Mouth Organs of Honey-bee (*Apis mellifica*):
a, tongue; b, b, labial palps; c, c, first maxillæ.

curled up and retracted into the lower end of the mentum. It is capable of very rapid protrusion and of free motion in almost every direction. The external lateral portions or labial palps are comparatively small, and consist of two long and two short joints. Their tips remain as tactile organs, while their internal joints are elongated to form a sheath for the base of the tongue. Between the palps and the tongue there are also two very small structures known as *paraglossæ*. The whole proboscis thus consists of hairy tongue, of minute paraglossæ, of insheathing labial palps (all belonging to the second pair of maxillæ), and further, of external maxillary blades and reduced palps belonging to the first pair. The hairs which cover the tongue appear to serve for the upward passage of honey. The successive whorls have been seen to be erected from before backwards so as gradually, but rapidly, to sweep the nectar to the mouth. The expanded lobe at the tip of the tongue is thrust into the nectar, and a little appears to pass up a central capillary tube to the taste organs, by which the bee determines whether the food does or does not suit its taste. The tip may also be used to lick flat surfaces. The upward passage of the nectar among the hairs on the outside of the tongue and within the outer sheath is doubtless helped by the sucking action of the sides of the body, and of the first part of the food-canal. According to a recent investigator (Breithaupt), the honey may pass up either by the great suctorial tube of the proboscis, or when that ceases to be efficient, by the capillary tube of the tongue, but the exact action of this complex and beautiful organ is not yet thoroughly understood. The tongue of the workers is twice as long as that of the queens or the drones, who do not collect honey.

The somewhat oval *thorax* bears the two pairs of wings and three pairs of legs, and consists of the usual three segments, of which the most anterior (the prothorax) is greatly reduced. The wings,

which are borne on the last two segments, are membranous and transparent. When at rest, they are folded together over the back; when in action, the two pairs are clasped together by means of small hooks on the fore margin of the hind pair. Perhaps it was this close union of the wings which suggested to Linnaeus the name Hymenoptera or 'wedded-wings,' though the term may simply refer to the fact that the wings are membranous. The arrangement secures a very steady and rapid flight. The many-jointed mobile legs do not differ from those of other insects, except in the high development of pollen-collecting hairs. In the workers the hind pair of legs exhibit on their central joint a spoon-shaped cavity fringed with bristles, so as to form an efficient pollen-basket. The pollen is kneaded by mouth and fore-feet, and shifted by the middle pair of legs to the safe hollow behind. The two terminal claws of the feet are used when the bees climb and hang, while the membranous lobe between the hooks probably aids in handling minute bodies and in clambering on smooth slippery surfaces.

The *abdomen*, or posterior portion of the body, is joined to the thorax by a comparatively narrow bridge. The margins of successive segments overlap, and the whole region is capable of free respiratory movements. Like other parts of the body, the abdomen has a dark-brown colour, with somewhat lighter cross bands. The females bear at the end of the body an ovipositor or sting, which consists of a median piece deeply grooved on its lower surface and of two adjacent sharply pointed structures, which being apposed to the median piece, make the groove into a canal. The internal end of the canal thus formed is in connection with the female generative aperture, so that the eggs can pass neatly down from the body of the bee into the cell prepared as a cradle.

curved organ, which is occasionally used as a weapon in duels with rivals, but much more frequently for its main business as an egg-laying organ; in the workers it is rarely used except as a sting; in the drones it is represented by the external male genital organs.

The Internal Anatomy—The Food-canal.—The nectar drawn up by the proboscis passes into a short pharynx, and thence into the gullet or honey-bag. This forms a long slender tube dilating into a transparent bag, filled with honey in the bees returning heavy laden to the hive. On the anterior region of the gullet, near the mouth, are several pairs of lobed salivary glands, the secretion of which is used in kneading the pollen into pellets, and in the labour of cell-building. In the honey-bag the nectar begins to undergo chemical change, and so much of it passes onwards into the digestive (chylific) stomach. At the end of the stomach are the usual excretory (Malpighian) tubes, opening into the beginning of the intestine. This dilates into a rectum before ending at the anus.

The Nervous System.—As in other insects, the nervous system consists of a ganglionic mass above the gullet—the brain, and of a ventral chain of ganglia, of which the anterior are connected with the dorsal mass by means of a nerve-ring round the gullet. The two posterior ganglia in the thorax are fused into one, and beyond this are five or six abdominal ganglia. The presence of these separate nerve-centres or ganglia in the body explains the apparent vitality of bees and other insects for some little while after the removal of the head. Reference has been already made to the compound eyes and to the ocelli. The location of the sense of smell is doubtful, though apparently in one or more of the mouth-appendages. The results of experiment as to the presence or absence of auditory organs are still for the most part negative.

The circulatory, respiratory, excretory, and reproductive systems do not differ markedly from those of other insects. The usual dorsal chambered heart is present. The main stems of the tracheæ or air-tubes, by means of which the air passes throughout the whole body, are very large and dilatable, especially in the abdominal region. The buzzing of bees is partly due to the rapid movement of the wings, and partly to the vibration of the stigmatic membranes which guard the entrance to the air-tubes. The excretory system is represented by the long fine Malpighian tubes already noted as occurring at the beginning of the intestine. The queen is the only female with fully developed reproductive organs; the workers are infertile females, though the skilful dissections of Miss Jurine demonstrated the presence of small ovaries, from which drone-eggs are very exceptionally produced. This occasional fertility has been plausibly explained by supposing that some of the 'royal bread,' which is necessary to rear the queens, falls by chance into cells for which it was not intended, and thus affords a slight additional food-stimulus sufficient to insure in an ordinary worker-grub some development of reproductive organs. The fertile worker is said not to appear unless the hive has long been queenless; it has therefore been suggested that the desire for brood may have stimulated their reproductive development. The female reproductive organs of a queen-bee consist principally of ovaries, oviducts, ovipositor, and a storing chamber for the male elements, known as the spermi-reservoir or spermatheca.

Functions and Habits.—It has been already noted that the social life of bees has resulted in some division of labour. At the beginning of spring the hive contains a single queen and

Fig. 2.—Sting of Worker-bee (*Apis mellifica*).
(After Kraepelin):

a, poison gland; b, poison bag; c, accessory gland; d, d, outer supporting pieces; e, inner sheath inclosing sting proper.
A, sting proper; B, sheath in which sting works, seen from below.

But the base is also connected with a poison-bag containing formic acid and other irritants, which are squeezed into the wound made by the sharp sting, and are the obvious causes of the familiar inflammation. In the queen-bees this specialisation of abdominal appendages forms a long, stout,

a much-reduced contingent of workers. Their first care is to restore the normal population. Towards this end the queen lays numerous eggs which develop into *workers*. After the stock has been thus replenished, eggs are laid which turn out males or *drones*. After they begin to appear, eggs are laid which develop into more workers, and also into a few *queens*. The rapid increase of population culminates in the emigration known as *swarming*, when the old queen leads off a large contingent of subjects. The date of swarming is markedly affected by the temperature and the food-supply. The symptoms of emigration are such as these—a clustering of bees in small dense crowds outside the hive, a commotion among the drones, a suspension of the labours of the workers, the excitement of the queen-mother, and, in the case of second or third swarms, the piping of the still imprisoned young queens. She is exasperated by the presence of possible rivals in her own household, and would ruthlessly kill her royal children, were they not guarded by the workers. In the case of swarms centred around an old queen, it seems customary to send out scouts to explore the land before the bees take any decisive steps towards emigration. When at length the pressure and excitement has reached a climax, the emigrants rush out with great rapidity. They form a spreading crowd, concentrating, however, round the egg-laden queen, who is rarely able to fly far. During swarming, the bees are singularly quiet, and may be safely handled. Should the queen be lost or removed, the bees soon return much depressed to their old home. The workers seem to take with them a heavy load of honey, and they at once set about building a comb, in the first cells of which the queen, losing no time, lays some eggs. The disruption of swarming obviously robs the old hive of its queen, but there are princesses ready to be liberated, and these may soon lead off fresh swarms.

A populous stock will often send off three in rapid succession. When the season and necessity for swarming is past, the young queens that remain imprisoned in the royal cells are liberated at once and allowed to fight for the sovereignty. The survivor takes her nuptial flight. By one, or perhaps several, of the males she is impregnated, though some authorities believe that the fertilisation is effected by drones from another hive. After impregnation has been accomplished, the young queen settles down to begin her egg-laying; she continues this throughout the rest of the summer. When swarming time is over, and the supply of honey decreases, the bees commence to rid the hives of the drones, henceforth mere useless consumers. They appear to drive them into a corner, and keep them without food until their

suggests the difficult problem of the meaning of so many males. Their number, of course, insures the fertilisation of the queen. Romanes suggests that the numerous drones represent a survival of past times when the society was less complex, and when the females were probably more numerous, and the males less idle. If there is any chance of drones being needed, when for instance the queen is barren, and fresh ones have to be reared and fertilised, they are allowed to live beyond their usual term. On the other hand, when unfavourable weather prevents swarming, the workers in their despair sometimes massacre the drones.

The queen-bees are reared from special eggs, which begin to be laid after the drones appear on the scene. According to some, the queen herself deposits in the special royal cells the eggs which develop into future queens; according to others, the workers shift the eggs into these specially large cradles. They develop very rapidly in consequence of rich nutrition, attaining their maturity in about sixteen days. The queen is always treated with much respect and care, unless she turn old or become barren. An intruding stranger-queen is not always treated with respect, but may be pulled about by the workers for hours until she dies, and is thrown out of the hive. A queenless hive, without any prospect of a new sovereign, becomes completely demoralised and restless, but in this case a stranger is gladly adopted.

Just as the drones and queens maintain the numbers of the hive so far as reproduction is concerned, so the supplies of food are collected by the myriads of workers. Among these there is some slight division of labour. Members of the community varying in age and constitution, are told off to special tasks. Thus we can distinguish the external workers who collect nectar and pollen from those who attend to more internal domestic duties. Some of the internal workers, usually the young bees, act as nurses, effecting the mastication and semi-digestion of the food for the young larvae, and caring for all the needs of the brood; while some wait upon the queen. Others again devote their energies, for a time at least, to the architecture of the cells, for which some of the heavy eaters secrete the wax. Others attend to the ventilation of the hive, which is apt to become hot enough not only to be disagreeable, but to soften the wax. These ventilators fan industriously with their wings, and produce air-currents through the hive strong enough to blow out a lighted match. 'When they are tired they are relieved by others.'

Feeding.—Bees feed principally on the nectar and pollen of flowers. In spring they frequent the early-flowering willow, hazel, plane, apple, pear, alder, gooseberry, currant, &c. Later on they turn to the crowfoot, clover, vetch, turnip, cabbage, dandelion, buckwheat, balsam, privet, elder, bramble, and other flowers, which yield abundant nectar and are accessible to their probosces. The borage, the mignonette, the thyme, the heathers, the teasel, are also valuable sources of food. Plants like the furze, which keep flowering for a long time, are obviously of great value to bees and bee-keepers. Some flowers abounding in nectar are avoided because of their strong smell, others like the red clover and the honeysuckle are inaccessible to bees with a proboscis not larger than that of the common hive-bee. Attempts have been made in Britain to rear varieties which would be able to utilise the abundant red clover, inaccessible to the common bee.

When the bee proceeds to rob a flower of its nectar, the tongue, folded up when at rest, is protruded beyond its ensheathing parts, and is pushed as a probe into the flower-tube. By the action of the hairs on the outside of the tongue, or by the

Fig. 3.—Honey-bee (*Apis mellifica*): A, queen; B, drone; C, worker.

powers of resistance are much weakened. They are then turned out of doors to perish, for the workers seem rarely to use their stings. Even the infant pupae and the eggs are destroyed. The fact of this massacre

general action of the suctorial proboscis, helped by muscular contractions of the body, or by an ascent up the fine capillary tube of the tongue, the nectar is conveyed to the mouth. Thence it passes down the gullet into the honey-bag, and is partly used for the sustenance of the worker itself, being digested in the stomach, and passing thence to the body generally. A large surplus, however, remains as a contribution to the honey-store of the hive, which is stored up for consumption during the flowerless season. Where there is no real winter, as in warmer countries (Australia and California), imported European bees tend to lose their storing instinct, and to become idle.

Besides the nectar, the *pollen* of flowers is essential to the normal life of bees; it is the ambrosia of the hive, and is largely used as food for the young. As the nectar is non-nitrogenous, the necessity for some other kind of food is obvious. Drones and queens, however, never eat raw pollen, and must therefore get their nitrogen indirectly. The special food supplied to the young is formed from pollen partly digested along with honey. The pollen is collected by the hairs of the body, from which it is cleaned off by the feet and jaws, damped with dew or other moisture, mixed with a little honey ejected from the mouth, kneaded into pellets, taken up by the brushes on

the hind-legs, and deposited in the baskets in which it is carried home. The cargo thus brought to the hive may be immediately seized by the nursing bees, or may be stored up for future use. In the first case it is worked up by the nurses into a suitable state and given to the larvae. In the other case the worker frees itself from its burden, pulling it off with its fore-

Fig. 4.

(*Bombus lapidarius*), B.

legs over a cell in the comb, and starts off again for more, while another bee packs the pollen into the cell, with the addition of a little honey, and covers it over with a varnish. The industrious collectors restrict themselves on each journey to a particular kind of pollen. Bees may also consume the juices of plants, and do not hesitate to suck the bodies of the deceased or murdered grubs. In periods of scarcity, large quantities of the juices ('honey-dew') of aphides, and other small insects, may be stored.

It is difficult to understand on the principles of a selfish philosophy the extraordinary industry of the workers in their food-collecting. It cannot be called greed, since it is more for the good of the society than for their own. It is also well known that the rage for plunder often prompts bees to engage in warfare. Many individual bees try robbery on their own account, attempting to sneak into neighbour hives. In other cases four or five act in concert as highway robbers, waylaying some honey-laden victim, and outrageously despoiling it. It is even said that simple intimidation sometimes results in a submissive handing over of spoil. But in other cases a whole army of bees attacks a hive probably supposed to be at once rich and weak.

Their first care is to demoralise their enemies by killing the queen. This done, the rest is generally easy, and the panic-struck owners may even help the invaders to carry home their own honey.

Bees also collect a resinous, strongly adhesive, reddish-brown substance, known as *propolis*. This is obtained chiefly from the resinous exudations of such trees as fir, poplar, alder, birch, willow, horse-chestnut, &c., and is much used by the bees as a cement. With it they varnish the combs, stop up holes, and 'strengthen the outworks of their city.' It may also be used for stranger and more occasional purposes, such as sealing up an intruding snail. The bees carry it home on their legs; other workers clean it off, and utilise it while still ductile, mixing it with various proportions of wax according to the use to which it is put. Bees also appreciate the honey-dew which appears on the leaves of many trees and herbs, usually in association with aphides.

Secretion.—The wax used in the construction of the comb is manufactured by the bees themselves. It has been shown that they are able to form it even when fed exclusively on honey. After a heavy meal, they often hang together in a small festoon, and secrete large quantities in this state of repose. The secretion is exuded from eight wax-pockets situated on the ventral surface of the abdomen. The wax projects in small flakes between the rings, is removed by the legs, shifted forward to the mouth, masticated by the jaws, and laid in heaps for the use of the comb-builders. In a young hive these wax scales may be found in thousands upon the floor.

Another secretion of a very different nature is the poison. This consists of a transparent fluid with much formic acid and other irritant components, and is secreted by workers and queens in a venom-bag situated near the end of the alimentary canal. There the waste products of honey literally form poison, which flows down between the two barbed piercing organs forming the main part of the sting. The scabbard or sheath of the sting has been already referred to as the ovipositor. The barbed form of the sting makes it very difficult for the bee to withdraw it after striking its foe, and thus death is generally the nemesis of passion, though, as we have seen, this is avoided in the massacre of the drones. The queens have longer and stouter stings than the workers, but are very slow to use them. They rarely have occasion to do so in fact, except in their duels with other rival queens. The best precaution against being stung is quietness. Of the numerous curative applications, ammonia solution (hartshorn) is one of the most serviceable. See POISONS.

In regard to secretion, it is only necessary to notice further that the bee-larvæ, like so many other young insects, secrete a certain amount of silk to form chrysalis-robes.

Hive-life.—During winter and early spring the bees remain at home, but the temperature of the hive (usually 45° F. at least) shows that they are not asleep. In March or April the work of the year begins—the hive is cleaned, the dead bodies are removed, and the queen begins to lay. How the first eggs produce drones, which issue forth in twenty-four days; and how in midsummer some eggs develop into young queens; how the birth of workers increases the population of the community, much reduced during the winter; and how in a short time a swarming occurs, are familiar facts which have been already noticed.

Cell-building.—The bee 'combs' consist of a series of waxen cells constructed by the workers for storing honey and as cradles for the young. They hang perpendicularly within the hive, firmly fixed to the walls. Each consists of a double

row of cells disposed at right angles to the comb. Each cell of this two-sided comb is a hexagonal prism, with its internal apex lying in the depression between three adjacent cells on the opposite side. Of the three figures—the equal-sided triangle, the square, and the hexagon—which can be packed together without interstices, the hexagon is strongest and most convenient. To have the bottoms of the cells formed from three planes of adjacent cells on the opposite side economises labour and material. The amount of possible saving varies with the angle at which the three planes meet. Maclaurin showed by calculation that the angle of the bee-cell was mathematically the best. Though perfect regularity is disputable, there still remains a marvellous accuracy to be explained. On the one hand, some supposed, and one may almost say suppose, that the bees really know what they are about, and that they have by experiment solved the problem. On the other hand, others have tried to give either a mechanical or an historical explanation of the beautiful result. Thus Buffon sought to explain the hexagonal form as the result of the mutual pressure of crowded cylinders. He called attention to analogous results when soap-bubbles are crowded together, or when peas crammed into a bottle expand with boiling. While some, like Brongham, who have repeated this last experiment, denied that regular hexagons resulted, others have corroborated Buffon, and asserted that some of the figures formed are those of the bee-cells. Buffon's mechanical theory was, however, discredited, and indeed laughed at, by most authorities on bees, and the assumption which flattered the intelligence of these insects held ground till Darwin attacked the problem.

Darwin discussed the facts in the main from an historical point of view. He pointed out that at one end of a series the humble-bees either use their old cocoons for honey storehouses, or improve them slightly by the addition of short tubes, or build separate irregular rounded cells. At the other end of the series the hive-bees build their beautiful framework. But between these there are gradations, especially that exhibited by the Mexican *Melipona domestica*. This bee makes a comb of cylindrical cells for its young, and larger spherical cells for honey. These are placed so close that if the spheres were completed they would intersect. This is not, however, permitted, for the bees build flat plates between the cells which tend to intersect. Thus each cell presents an outer spherical portion and two or three or more flat surfaces. As one cell often rests against three others, a pyramid is formed by the union of three flat surfaces. Now if the *Melipona* made its spheres at a given distance from one another and of equal size, the result would be the hive-comb type. Darwin then resorted to experiment. He placed plates of wax in the hive, and on these the bees proceeded to excavate circular pits at equal distances, so that as they were completed the surfaces intersected. When this occurred, the bees built up flat walls along the lines of intersection. 'The work of construction,' he says, 'seems to be a sort of balance struck between many bees, all instinctively standing at the same relative distance from each other, all trying to sweep equal spheres, and then building up, or leaving ungnawed, the planes of intersection between these spheres.' Darwin thus called attention to the gradual evolution of the habit from less perfect expressions, and appealed, of course, to natural selection as tending to develop an instinct which was obviously economical of space, material, and labour. This account of the historical evolution of the habit does not, however, exclude the possibility of purely physical

factors having much more to do with the actual solution of the problem than Darwin supposed. A recent investigator of this much-debated point, Dr Müllenhof, reverts very much to Buffon's position. After emphasising the perfect plasticity of the wax at the temperature of comb-building (27° – 37° C.), he maintains that the beautiful result is not due to any artistic dexterity on the part of the bees, nor to any direct effect of their body-form, but 'to statical pressure according to the laws of equilibrium.' The cells are such as would naturally result from pressing the maximum number of cylindrical cells into the minimum of space. They really behave, he maintains, as softish cylinders would do in conditions of mutual pressure and continued plasticity. They form equilibrium figures with the smallest surface for given contact. But at anyrate it is, on the one hand, certainly gratuitous to credit the bees with the mathematical insight of senior wranglers, and equally unnecessary, on the other, to ignore the neatness and precision of their manipulation.

Into some of the cells honey is placed for winter use. In going up and down over the full cells, bees have been seen to protrude their stings, and to deposit drops of poison on the honey. This has an antiseptic influence, due to the presence of formic acid, without which the honey would ferment. In other cells pollen is stored after being salivated and compressed by indoor workers. A pollen-cell is (frequently at least) sealed with honey, and over this a thin cream-like pellicle is formed, which can be pushed aside for the deposition of more honey, or walked over without causing overflow. But of equal importance are the brood-cells, the cradles of the future young bees. These vary slightly in size. Those for future workers are smaller and lower; those for the drones are broader and longer. In spring-time, after the drones have begun to appear, the royal cradles are formed for the young queens. These cells are usually made at the edges of the combs, have their mouths turned downwards, and are of a large size and more irregular form. In other cases they are merely modified worker-grub cells.

Life-history.—As in the majority of insects, the life-history is divisible into four chapters—the developing egg, the larva or grub, the pupa, and the perfect insect. (1) The eggs have a long oval shape, and a whitish colour. They are, barring an exception already noticed, all laid by the so-called queen. After normal fertilisation she becomes, in fact, little more than an egg-producing machine, turning them out sometimes at the rate of 100 per hour or 3000 per diem, and is often fed while at her work, so that the expenditure of living matter is to a certain extent recouped. If a young queen be not impregnated in the first three weeks of her life, she continues laying drone-eggs only, as above described. The discriminative process of fertilisation of the ova is highly noteworthy: in laying an egg in a worker-cell the queen's abdomen has to be contracted, and a drop of seminal fluid is thus brought into contact with the egg; in the case of the larger drone-cell there is no such abdominal contraction, and consequently no fertilisation of the ovum. The egg is fixed by its end to the base of the cell, and thus it remains for between three and four days, when the worm-like grub appears. (2) The grub grows like any other insect larva, and as it touches the sides of its cell, coils up in a crescent, and floats in the food which has been left in the cell. As it gains strength, however, it rears up to the mouth of the cell and eagerly devours the food supplied by the nursing workers. After the sixth day the worker-grubs only receive unmanicured food. The result is the stunting or atrophy of their reproductive

system. With the queen-grubs it is very different. The grub is seen literally wallowing in the rich and carefully elaborated royal jelly; and this abundant and stimulating nutrition is naturally believed to be the condition of the perfect development of the reproductive system exhibited by the queen-bees. (3) In several days, varying slightly with the season, the grub passes into another stage of its life-history. It has grown greatly and accumulated some reserve material to serve it throughout a period of fasting. The cell is sealed up by the nurses, and the grub becomes a *pupa*. The queen is $5\frac{1}{2}$ days a larva and $8\frac{1}{2}$ days a pupa, the worker 6 and 11, the drone 6 and 15 days respectively. The nursing workers seal up the cell with a cap of wax, which is more convex in the drone-cells, and in all cases different from the paler, somewhat concave, cover of the honey-cells. The imprisoned grub does not at once fall into inactivity, but proceeds first to spin its chrysalis-robes. Alternately contracting and elongating its body, it at the same time allows filmy threads to exude from the orifices of spinning-glands situated on its lower lip. There are two such organs, and the resulting thread which the grub weaves round itself is therefore double. In a day and a half the worker-grub has spun a complete cocoon, and becomes a true resting pupa or bee-nymph. The male-grubs also spin complete cocoons, but those of the queen-grubs only inclose head, thorax, and the first ring of the abdomen. In this connection it is worth noticing, as an illustration of depraved teleology, that, according to Hübner, the final cause of these incomplete cocoons is that the pupae may be more readily exposed to the sting of the jealous first-born queen, whose instinct prompts her to kill off all possible rivals.

Within the curtain of the cocoon important changes occur. The mummy-like pupa is gradually modified into the young bee. The skin, the segments, the appendages, and the internal organs undergo most marked changes, and on the twentieth or twenty-first day after egg-laying the young insect finally bursts its swaddling-clothes, and emerges as a winged perfect insect or *imago*. They break open their cocoons with their jaws, and are assisted by the kindly workers; they clean themselves of moisture and shreds, and proceed to eat after their long fast. In some cases, after a preliminary meal, they proceed at once to gather honey, but the first flight is usually postponed for about a week, the intervening time being spent in indoor employment. The empty cells may be repeatedly used over again as cradles, or may be filled with honey. The young queens are not allowed to escape when their metamorphoses are over. In the door of their cell a small hole is made, through which the royal prisoners are fed till the tone of their piping probably intimates their complete sexual maturity. If the queen should be lost, and there be no royal grubs, a new queen may be literally manufactured. A young worker-grub is simply fed up to the required pitch in an enlarged cell of the proper spaciousness.

The different members of a bee-community enjoy lives of very varied duration. The drones live from May till August, but were it not for the massacre, would doubtless live much longer. Contrary to the opinions of the ancients, who credited bees with an existence of as much as six or even ten years, the workers seem to have in summer an extremely short but hard-working life, which probably averages about six weeks. Those born in autumn live on till the next spring, though many perish in the hard times of winter. A queen, on the other hand, will live from three to five years.

Parasites of Bees.—Besides having cause to fear

open enemies like the death's-head moth, bees are, like many other insects, subject to the attacks of parasites both on their bodies and within their nests. On the adult bee lice are common pests, while the larvae of the ichneumon do great damage to the grubs. Honey-bees, however, are apparently exempted from the attacks of the latter, which appear to be unable to gain access to their dwellings. The adult honey-bee is greatly troubled by the Bee-louse (*Brachia cava*) and by the Bee-fly (*Phora incrassata*). The larvae are often devoured by a species of beetle (*Trichodes*). A hairworm of white appearance occurs abundantly inside the drones only—a somewhat remarkable fact, since it is not they, but the workers, which frequent the water-pools where the eggs of the worm are deposited. The wild bees are similarly infested by numerous parasites, such as the larvae of ichneumons, the minute *Anthophorobia*, which may be obtained in hundreds on breaking open a few cells of the leaf-cutter and other species. From larval intruders found in the nest of the wall-bee Lampert reared no fewer than nine different parasites belonging to the Hymenoptera, Coleoptera, and Diptera. Parasitism also occurs between bee and bee. Thus, the 'cuckoo-bees,' *Apathus* and *Nomada*, live at the expense of hosts no larger than themselves, with which, however, they seem to preserve a curious sort of harmony. On the other hand, the larvae of *Stelis nasuta*, found in the nest of the Wall-bee (*Chalicodoma muraria*), seems to devour not only the food, but the lawful tenants.

Senses.—The sight of bees is well developed; they are able to distinguish objects at some distance, and show a marked preference for certain colours, as might be almost inferred from the history of bee-fertilised flowers. Sir John Lubbock has shown by experiments with baits of honey on strips of paper of different colours that they can distinguish green, yellow, red, and blue, and prefer blue to all. Pink also appears to be a favourite colour. Like other insects, they are attracted to light. Much has been observed in regard to the power bees have of finding their way straight home. Lubbock's careful experiments have shown that the so-called 'sense of direction' is not in all cases a sufficient guide, but must be aided by definite registering of landmarks over the space traversed. This they are certainly able to do, and they can also remember their visual impressions for a considerable time. The sounds made by bees at their respiratory openings or stigmata are not restricted to a monotone, but vary considerably, as in the familiar case of the responses of the queen-bee to the piping of the princess pupae. From the variable sounds, apparently expressive of emotion, it has been inferred that bees are also able to hear. Sir John Lubbock was, however, unable to get them to take any notice of any sound which he could devise, though he is disposed to believe that they can hear higher notes.

Some of the mouth parts, such as the inside of the tongue, evidently act as organs of taste, and are able to discriminate between different kinds of nectar. Bees have also an acute sense of smell, but how far this is physiologically separated from taste is uncertain. It is probably by a fine sense of smell that bees are able to recognise the members of their own hive, and to detect an unwary wanderer or thievish intruder of another house. Sprinkling them with some strong scent appears naturally to obliterate this power. In connection with the recognition of strange bees, it is worth while quoting Mr Langstroth's observation that a stranger laden with honey is received with open arms, while a hungry marauder is very summarily dealt with. 'There is,' he says, 'an air of roguery

about a thieving bee which, to the expert, is as characteristic as are the motions of a pickpocket to a skilful policeman. Its sneaking look, and nervous, guilty agitation, once seen, can never be mistaken.'

Sir John Lubbock's experiments have shown that bees possess a certain power of communication, and other observers also, such as Fritz Müller, have recorded cases where the workers were able in particular ways to bring their friends to some treasure-trove, or in some way told one another the sad news of the loss of their queen, and the like. How they can communicate any definite impression to their fellows is a mystery, but observers have noted that they tap one another with their feelers, and that the notes emitted from their respiratory apertures differ somewhat in character. The antennae are most essential organs of sensation; and an animal deprived of them exhibits a high degree of bewilderment and incapacity virtually amounting to insanity.

Intelligence.—Bees have thus keen sight, enabling them to distinguish objects and colours; acute smell, quick to detect, for instance, stranger bees or attractive food; and presumably a fine sense of hearing, fit to discriminate between the import of slightly varying tones in one another's voices. But they have more, inasmuch as they exhibit in their actions what can only be fairly described as intelligence. Without entering into any discussion, it may be useful here to recall the rough distinction between those instinctive reasonable actions which have become habitual, and those which exhibit a power of accommodation to new conditions or change of habit in the face of new problems. This whole subject, so far as at present understood, is well discussed in Romanes's *Animal Intelligence and Mental Evolution*, on the first of which the following summary is based. To begin at a comparatively low level, bees exhibit indubitable instances of *memory*. They are not only able accurately to register visual impressions of a locality so as to be able to find their way thither, even after considerable intervals, but they can associate their impressions so as to be able, for instance, to recognise a human friend, and have in some cases been tamed and trained. Sir John Lubbock also tells how a bee remembered what it had been shown—that the way out of a bell-jar held with its closed end against a window was not to endeavour to get through the pane, but out at the open end.

It is obvious further, from what has been already said of the habits of bees, that many features in their domestic and social economy suggest foresight and purposeful determination. Such a conclusion must, however, be made with great caution in regard to all actions or sets of actions which are distinctly habitual and shared by the whole race. That several surplus queens are reared to make up for losses; that worker-grubs can, if occasion demand it, be promoted by feeding into queens; that the young queens are not liberated till the old one leads off her colony, and then generally in gradual succession; that the workers allow the rival queens to settle their own affair by duel in which the fitter probably survives; that they massacre their drones when these are no longer of use; and that they do a dozen similar things, is doubtless marvellous, but the marvel must not at least be exaggerated by forgetting that they have been forced and drilled into these reasonable habits throughout the very long history of their social organisation. On the other hand, when an unusual juncture in the social relations occurs, and the bees act sagaciously in extraordinary conditions, then there is purposeful intelligence to admire. Thus Romanes quotes two observations of F. Hübner to the following effect:

Two sole surviving queens, prompted by their instinctive jealousy, were engaged in mortal combat, and were so situated that a simultaneous double sting would end the life of both—an obvious disaster to the hive. They released one another, and intelligence triumphed over instinct. And again, a hive was left queenless, with the not uncommon result that the remaining bees set about manufacturing some new queens from worker-grubs. Hübner restored the old sovereign, and the bees at once proceeded to remove the royal food from the worker-grubs, so as to counteract their previous, but no longer useful intention of rearing new queens. The submission of the bees of an invaded hive when they find that their queen has been killed, is also a curious instance of discretion, and the variations occasionally exhibited in connection with drone-killing, are no less suggestive of intelligence. Again, it is a fact, which any one can verify, that bees bite through the corollas of many tubular flowers near the nectaries, in some cases as a lazy trick to save time, in other cases as an ingenious device to reach nectar inaccessible by the normal process of stretching the proboscis down the corolla tube.

The careful *ventilation* of an over-heated hive is evidently an adaptation to an abnormal state of affairs which would not occur in the roomy natural hives, and ought not to occur in the artificial. 'It follows,' Biechler writes, 'that the fanning and ventilating can have absolutely nothing to do with an inborn tendency or instinct, but have been gradually evoked by necessity, thought, and experience.' In regard to *cleanliness* also, intelligent adaptations of much interest are exhibited. When possible, the excrement is voided outside; in winter the faeces may be retained till the first fine day; bees have even been known to make a kind of drain for the removal of the waste matter, which, when voided in the hive, often causes dysenteric and other fatal diseases. Small intruding animals, such as slugs, are known to be sealed up with propolis, while an intruding mouse, for instance, too large to be safely left in this way, was killed, and gnawed into bits, which were carried piecemeal outside. The bodies of deceased bees are also removed outside the hive. In regard to their *treatment of intruders*, besides the welcome of those bearing gifts, and the rough detection of those with evil intent, their clever device by which they fortify the hive against their formidable enemy the death's-head moth is extremely suggestive. Hübner was the first to notice that, as the result of repeated attacks, the bees were taught by sad experience to build at the entrance a barrier of wax and propolis, with a hole large enough to admit them and small enough effectually to exclude the invader. Whatever opinion may be held in regard to the intelligence displayed in the habitual *architecture*, there can be little doubt as to the inference to be drawn from cases in which the building habits are modified to suit peculiar conditions. Bees have been seen to make repeated trials of different plans in special cases, as when two combs meet at an angle, to pull down bad workmanship and rebuild it, to adopt ingenious devices when the sides of the hive were made of smooth glass, and so on. To Hübner 'the purest reason seemed to shine out' from the action of the bees in a hive where a piece of comb fell from its proper position. Wiser than many builders, they strengthened the attachments of all the other combs, 'clearly because,' as Romanes notes, 'they inferred that they too might be in danger of falling.' Many similar instances have been recorded.

Emotions.—The intellectual development associated with the complex social relations of bees seems much greater than the culture of their emotions.

Sir John Lubbock describes them as 'thoroughly callous and utterly indifferent to one another, except, indeed, when attention to their comrades was for their own advantage, or part of the ordinary business of their life. He notes how they pay no regard whatever to the sudden death of a comrade beside them, nor even to the struggles of one in trouble. Other observers, both ancient and modern, give them credit for a little more sympathy, and have noticed cases, perhaps exceptional, where they did seem to exhibit active compassion for an unfortunate fellow-worker.

Relation to Flowers.—It is now well known that in the majority of flowering plants the female cell is fertilised by male elements or pollen grains carried by insects from another flower of the same species. Insects, more especially bees, and flowers have, in fact, grown up together in mutual dependence and with mutual influence. They have perfected one another. Bees are attracted to suitable flowers partly, no doubt, as the result of experience, but also by odours, and especially by colours.

Fig. 5.

A. Honey-bee on broom-flower; B. Wild-bee on white dead-nettle.

These colours exhibit a gradual evolution from yellow to blue. They 'follow a regular law of progressive modification, but have been fixed and stereotyped in each species by the selective action of the proper beetles, bees, moths, or butterflies.' Blue colour is characteristic of many highly-developed flowers, and bees are especially fond of this blue colour, probably because they have learned to associate it with flowers peculiarly suited to their access and taste, and the result of this preference is to insure the fertilisation and survival of the higher flowers. And again, numerous flowers, especially those visited by the higher bees, exhibit mechanical adaptations which insure that the bee in diving down for the nectar becomes thoroughly dusted with pollen. The wild sage (*Salvia*) and the orchis are two good examples of very different modifications securing fertilisation. There can be little doubt that at least the more mechanical of these pollen-dusting contrivances have resulted as direct adaptations in association with the continual visits of bees. See FERTILISATION OF FLOWERS.

Pedigree of Bees.—These adaptations are, however, mutual ones: just as flowers have been modified in relation to bees, so have bees in relation to flowers. Bees thus appear to be the last result of a long series of progressive changes, the steps of which are still to some extent discoverable. According to Hermann Müller, the primitive ancestor was a form like the common sand-wasp, carnivorous in its diet, and bringing its insect or spider prey to its larvæ. From these arose forms which adopted a floral diet, and thus filling up a more or less unoccupied corner in nature's household, got on amazingly well. They thrive, were

fruitful and multiplied, and were, in the course of time, likewise modified into the numerous types of modern bees. The chief modifications, as above noticed, are associated with the development of social life, the elaboration of honey-sucking mouth structures, and the equipment with pollen-collecting appliances. Müller's main stages are as follows:

(1) Starting from the sand-wasp, we find in *Prosopis* a bee but slightly advanced above the ancestral type. It is almost hairless, with mouth parts but slightly elongated, and feeds its young on honey and pollen, which are simply crammed into the brood-chamber. (2) *Sphecodes*, *Halictus*, and *Andrena* occupy a somewhat higher level. They are more efficient pollen-collectors, inasmuch as they have become hairy. In the first there appears the first trace of feathery-collecting hairs, and the primitive fashion in which they feed the young with the disgorged surplus of food is also interesting. *Halictus* has more hairy hind-legs, and special brushes on some of the terminal joints. The young are fed with pollen. In *Andrena* the whole hind-leg is hairy. (3) *Dasygaster* and *Panurgus* exhibit yet another step in the direction of more efficient pollen-collecting. The hairs occur on the long tibia (second-last portion) and on the terminal part or tarsus. (4) The last step in this direction is exhibited by those forms in which the pollen is moistened with honey before it is stowed away. In *Macropis*, heaps of consolidated pollen are fixed without special contrivance to the hind-legs; in *Bombus* (humble-bee) the outer side of the hind-legs exhibits the familiar pollen-basket fenced in with long hairs—an obvious economy of both hairs and time; while *Apis* (honey-bee) shows a yet more evolved arrangement of collecting-brushes and receiving-basket. Besides those forms with collecting-hairs on the hind-legs, culminating in *Apis*, there is a separate division, in which the pollen is collected on the lower surface of the abdomen upon brushes or backward-directed bristles. The mason-bee (*Osmia*) and the leaf-cutter (*Megachile*) are good examples. In the same way, Müller traces throughout a series of gradations the evolution of the honey-collecting organs. This progress is chiefly concerned with the lengthening of the tongue and the extension of the membranous and elastic parts between the bases of the two pairs of maxillæ (between mentum and cardines). The tongue is in the lower bees decidedly shorter than the basal joint or mentum, but ends with becoming very much longer. The first pair of maxillæ also elongate into insheathing laminae for the tongue, and the same is true of the proximal joints of the labial palps (i.e. of the external lateral portions of the second pair of maxillæ). In power of extension and retraction, in equipment with honey-catching hairs, in the differentiation of a terminal lobe, &c., the tongue exhibits a progressive evolution.

Evolution of Social Life.—Just as among ants, so with bees we have to distinguish solitary and social genera, of which the former are greatly in the majority, and, in origin at anyrate, the more primitive. Starting from completely solitary forms, we next find bees whose nests are individually separate, but at the same time closely adjoin those of their neighbours. From such a beginning the various grades of development up to the complex social life exhibited in the communities of humble and honey bees are still distinctly traceable.

(a) *Solitary Bees.*—*Colletes* is a common and widely-distributed genus, the females of which closely resemble the common honey-bee. The males differ in several features, and are decidedly

smaller. They form colonies of considerable size in loose soil or in the soft mortar of walls. Each cell is lined with a fine coating resembling gold-beater's skin. *Prosopis* is also a common bee of wide distribution. It closely resembles a sand-wasp, and is destitute of the usual means of carrying pollen, being on that account long regarded as a parasite. They make their cells in the pith of bramble-sticks, and line them, like Colletes, with a delicate membrane. The British species appear in June, and continue during the two succeeding months. When handled they give off a pleasant odour. The genus *Sphecodes* includes four British species, of world-wide distribution, but of infrequent occurrence. They also are often regarded as parasites on other bees (*Halictus*), but Mr F. Smith's observations go to show that both in burrowing and pollen-gathering they are entirely independent. The nests occur, indeed, side by side with those of *Halictus*, but each bee seems to keep to its own home. In spring females alone are met with, while in autumn both sexes occur together. The genus *Andrena* is the most numerous of all the Apidae, the British species alone numbering sixty-three. They have been fitly called the harbingers of spring, as they appear even in the cold of March. They are all burrowers, making holes which measure from 6 to 12 inches in depth, and give off lateral passages, each terminating in a cell. In this the female deposits its egg on the top of a mass of pollen about the size of a pea. After devouring this, the larva falls into a lethargy, which lasts till the following spring, when the rest of the metamorphosis is rapidly completed.

Halictus is a large genus, the members of which resemble *Sphecodes* in many characteristics, and in this among others, that they alone among solitary bees are impregnated in the autumn, and remain dormant during winter. The most beautiful bees found in Britain are the wasp-bees or *Nomada*. In their gay colours they resemble wasps. They are widely distributed in the northern hemisphere. Their life-history is still veiled in obscurity, little being known beyond the fact that they enter the lives of other bees (*Andrenidae* and *Apidae*). All the British species emit when captured very agreeable balmy odours. The mason-bee, or *Osmia*, includes a large number of species with most interesting diversity of instincts. They occur abundantly in temperate climates, and their nests are found in the most diverse localities, from the shells of snails to the branches of brambles. In regard to these wood-boring bees (such as *Xylocopa*), it has been a commonly received opinion, originating with Réaumur, that the young forms at the lowest portion of the excavated tunnel escaped first, and that the others followed suit in regular order from below upwards. Each young bee had thus simply to cut its way through the bottom partition of its cell, towards which its head was said to be pointed, and was thus not only saved trouble, but kept from disturbing the less mature inmates of the upper stories. This pretty observation is, however, denied by Mr Smith, with respect to the numerous British wood-boring bees. *Megachile*, the genus of leaf-cutters, is the most cosmopolitan of all genera of bees, and three hundred species are known to exist. They all excavate burrows in the ground or in wood, which they line with cuttings from the leaves or petals of flowers. *Anthophora* is a very numerous genus, of world-wide distribution, and includes one hundred and thirty species, of which four occur in Britain. Some of them are true carpenters, and others are burrowers.

(b) *Social Bees*.—The genus *Bombus* includes one hundred species, of which twenty are British. Of all the wild bees, the species of *Bombus* (humble-bee) are the most familiar, being extremely conspicuous on account of their large size

and noisy hum. In different parts of the country they receive different names, such as humble-bees, hummel-bees, dumble-dores, foggie-bees, &c. Some species build their nests on the surface of the ground amongst moss and grass (e.g. *B. muscorum*, *B. pratorum*, and *B. elegans*), while others form subterranean homes (e.g. *B. lapidarius*, *B. subterraneus*, *B. virginialis*). At the first approach of spring, the females, which have been hibernating, come forth from their retreats, and at once set about establishing a homestead, choosing for instance the deserted abode of a shrew, or simply looking for a cosy nook on the surface. Having found a convenient site, the bee builds a nest of withered grass, moss, &c., in the centre of which a mass of pollen mixed with honey is then deposited. On this she lays several eggs, side by side, and covers them over with pollen. When the eggs hatch, the larvæ eat their way in different directions into the surrounding store until they reach their full growth, when they spin for themselves a strong oval cocoon. At the side of the mass are a set of shallow receptacles containing coarse liquid honey. These are probably designed either for the moistening of the pollen, or as a store for a rainy day. Within the cocoon the larvæ soon become perfect insects, but are not on emerging ready for active work, nor equipped with their full-coloured dress. The empty cocoons afterwards serve as store-chambers. The workers appear to issue first, and to take upon themselves the entire maintenance of the colony, while the queen now restricts herself more or less completely to maternal duties. Along with more workers small females appear, which are not unnaturally supposed to be only capable of producing drones. Later on the drones appear, while the last brood consists solely of large females, which, on being fertilised, hibernate, and thus complete the life-history.

The industry of the humble-bee appears to surpass that of any other bees, which is saying a great deal. From the earliest morning till the last streak of evening light, they seem to continue most indefatigably at work. The temper and courage of the different species varies very considerably; the nests of the surface-bees are readily taken, while the underground homes can hardly be outraged with impunity. No species is more courageous than the red-backed *B. lapidarius*. In autumn, however, the courage seems to wane, and a general listlessness prevails; the males especially being often found on the heads of thistles and other composites in a dazed and helpless state, capable only of twisting their legs over their head and back in a beseeching fashion, this condition being more probably due to the stupor caused by cold, than to over-indulgence in nectar. *Bombus* has a curious semi-parasitic double-goer, called *Apathus*, which is a very shadow of its host, and is thus able to enter the nest without molestation. The parent deposits her eggs in the pollen of a humble-bee nest, the larvæ are reared with those of the latter, and the adults enter and leave the nest as if perfectly at home. The association is by no means a friendly partnership, for the aristocratic idlers gather no pollen, and prey upon the innocent *Bombi* with which they live. They consist entirely of males and females, are veritable 'cuckoos,' and do no good to the flowers which they may visit.

Different Kinds of Honey-bees.—The genus *Apis*, to which the hive-bee (*Apis mellifica*) belongs, has a cosmopolitan distribution, and numerous local varieties have arisen in response to peculiarities of habitat and nutrition. The number of true species is a point of considerable debate. The fifteen enumerated in the General Catalogue of Apidae published by the British Museum, have

been reduced by Mr F. Smith to nine—viz. *A. dorsata* (India, Borneo, &c.), *A. zonata* (Celebes), *A. indica* (India, Java, Sumatra, &c.), *A. nigro-cincta* (Celebes, Borneo, &c.), *A. sinensis* (China), *A. florea* (India, Ceylon, Borneo, &c.), *A. adansonii* (Africa), *A. unicolor* (Madagascar, Rodriguez), *A. mellifica* (cosmopolitan). Of the last there are several varieties.

Within the limits of this article it has not been possible to do more than touch on some of the most important facts in regard to bees. Enough, however, has been said to show that the perfected complexity of their social state, the marvels and mysteries of their family relations, the exquisite adaptations of their structure, the dexterity and intelligence of their work, and the part they have played in the history of flowers, justify us surely in sharing the enthusiasm of those who, from the time of Aristotle downwards, have gained in the study of these insects some insight into the wonder and beauty of nature. See ANTS, FERTILISATION OF FLOWERS, HONEY, HYMENOPTERA, INSECTS, WASPS, &c.

BEE-KEEPING as a source of profit has largely extended in recent years, owing to the improvement of modern appliances, and the more thorough knowledge of the habits of the honey-bee. The only species of bee cultivated in Europe for its honey-gathering powers is the *Apis mellifica*. Of this, the leading varieties are the Ligurian or Italian bee, the Carniolan or Hungarian bee, the Cyprian, and the common black bee of our own country. Bee-keepers differ as to which of those varieties is the most profitable; but, as a rule, the Ligurian is most sought after. The Ligurian queens are more prolific, and the swarms are therefore larger. Their progeny seem to work harder during the honey-season, going earlier abroad in the morning, and working till later in the evening. In Italy and Germany, as well as in Cyprus and Palestine, the rearing of queens for exportation is largely carried on; and the different foreign varieties have been introduced into our country to such an extent that our own black bee is now scarcely ever to be met with in its pure state.

Hives.—It is necessary to the well-being of a colony of bees that their hives should protect them from the changeable influences of the weather. While the hive should be light, so as to be easily moved about, its walls should be thick enough to protect the bees alike from the extreme cold of winter and the excessive heat of summer, and should be constructed of a material that will effectually protect them from rain or damp. The hive in use in Britain for ages past has been made of straw, sewed tightly together with narrow belts of cane or bramble. The straw-skep answered the purpose of its construction very well. It was light and comfortable and durable, and formed a picturesque object. The straw-hive is unknown in the United States, the frame-hive being the only form known. In Russia, round logs of wood, hollowed out in the centre, are used. The introduction of the movable comb method of management has made the skep give way to what is known as the bar-frame hive; and now in many parts of Scotland and England the straw-hive is looked on as a relic of the past. The principle of the movable comb hive is of very ancient origin, having been employed by the Greeks; but it has been reserved to our own times to develop it. To the Rev. L. L. Langstroth, an American bee-keeper, belongs the credit of conceiving a hive in which the combs are built in frames, hung side by side in a box. The Langstroth hive made its appearance in the United States in 1851; and since then profitable bee-keeping has

advanced rapidly. The great advantage gained by the movable comb system of management is that the capacity of the hive may be regulated to accommodate any number of bees, however great or small. As winter comes on, and the bees decrease in number and cling more closely together, the hive is contracted by means of a division board, so that the internal heat is economised. As spring advances, comb by comb is added until the hive is filled. Other advantages of the method are that weak hives may be strengthened by combs taken from more prosperous colonies; that the drone-producing powers of the hive may be regulated, so as to allow breeding from the best stocks only; that on signs of anything having gone wrong in the economy of the hive, the bee-master is generally able to detect the cause, and to effect a remedy at once; and that the hive is so simple in construction as to be easily put together by any amateur joiner.

The frame, made of four bars of wood joined at the corners, is usually $14\frac{1}{2}$ inches long by $8\frac{1}{2}$ inches deep, and is made of wood about $\frac{3}{4}$ inch thick. If one examines a skep in which the bees have been allowed to work at will, it is found that the combs are about an inch in

Fig. 6.—A Bar-frame filled with Honey-comb.

thickness, and hang at a distance of about half an inch from one another. Accordingly, the frames are made 1 inch broad, and are hung at a distance of $1\frac{1}{2}$ inches from centre to centre. The number of frames depends on the size of the swarm to be accommodated, and on the honey-yielding capabilities of the district. Ten frames have generally been considered sufficient, although many bee-keepers use hives containing as many as fifteen or even eighteen frames. A hive, then, containing ten frames must be 15 inches long, 15 broad, and $8\frac{1}{2}$ deep. A passage of $\frac{1}{4}$ inch is thus allowed at the ends and under the bottom bar of the frames. If more than this be given, the bees will fill up the interval with comb, and if less, they will seal the frames to the walls and the bottom of the hive with propolis. The box thus constructed is the brood-chamber and storehouse of the bees, and is never despoiled of its sweets. It is necessary to provide accommodation for the storage of the surplus honey, of which the bees are to be deprived.

Fig. 7.—Section of Bar-frame Hive:

A, bar-frame with comb; B, walls of hive; C, floor-board; D, doorway; E, sectional super; F, cover of hive; G, quilt.

Bees, in their wild state, store the honey above the brood-combs; accordingly, a box of corresponding dimensions is fitted above the hive, while the whole is protected by a sloping roof. A doorway

6 inches in length, and $\frac{3}{4}$ inch in height, and a suitable floor-board, complete the bar-frame hive in its simplest form. Though the bars thus are hung at regular intervals, the bees would almost always work their combs irregularly on them, and the advantages of the frame-hive would be lost. To obviate this, guide-combs are fixed to the under side of the top bar. Thin pieces of old comb, or even strips of melted wax,

Fig. 8.—Bar-frame Hive, with cover raised to show arrangement of bars.

were formerly used for this purpose. A septum of wax has recently been brought into use, however, that answers this purpose perfectly. This is known as 'comb-foundation,' and consists of thin sheets of wax impressed in a machine on both sides with the forms of the base of the cells. The bees take to this at once, and work combs of perfect regularity and flatness. The strips of foundation used may be of any breadth, from $\frac{3}{4}$ inch to a full comb. By using full sheets the bee-master is able to control the birth of drones in the hive; for if worker-foundation—i.e. foundation bearing the impress of worker-cells—be used, the comb will necessarily be capable of containing only worker-brood. The bee-keeper is thus enabled to assist nature in preserving the fittest by breeding drones from his best queens only. Several thicknesses of carpet or felt are used as a quilt over the bars to confine the bees to their own chamber, as well as to prevent the escape of heat.

Quieting Bees.—Every one who has any knowledge of bees knows how rarely bees sting whilst they are swarming. This is owing to their being gorged with honey, when a bee will not sting unless hurt. If, then, the bees can be made to fill themselves with honey, they are in the bee-master's power. The general method of attaining this end is by blowing amongst them a little smoke. This may be done by a miniature bellows called the 'smoker,' in which a piece of cotton is kept smouldering; or a piece of brown paper rolled like a cigar may be used, from which the smoke is blown over the bees. A puff from a tobacco pipe serves the purpose equally well. The bees, frightened by the smoke, seem to fear that they are about to be driven from the hive, and they run to their store to gorge themselves, as they do preparatory to swarming, and in a few minutes they may be handled at will.

Swarming.—A pound weight of bees contains about 5000 individuals, and swarms are often found to weigh 8 lb., or even more. A populous hive will thus contain from 40,000 to 50,000 bees. In spring, however, the number is much smaller, amounting to only a few thousands. As the season advances and food becomes abundant, the

queen deposits her eggs at the rate of from 2000 to 3000 a day, and the colony soon becomes too numerous for the limits of their dwelling. Swarming is a matter of necessity, not of choice, on the part of the bees, and may be almost wholly prevented by providing sufficient accommodation for the increasing numbers. In Scotland, swarming rarely commences before the close of May, while in the south of England it is a few weeks earlier. The chief indications that a swarm is about to issue are the clustering of the bees at the entrance of the hive, and a cessation of the usual activity amongst the community. Previous to swarming, the bees gorge themselves with honey that they may have some store of provision for their new home. A first swarm will rarely leave the parent hive in bad weather. The time usually chosen is the early part of the forenoon, though a swarm has been known to go off as early as seven in the morning, or as late in the afternoon as five o'clock. The bees pour from the hive door in a constant stream. The swarm is not led forth by the queen as is generally supposed, for she is sometimes seen to issue amongst the stragglers at the close. They fly round in circles until the whole have left the hive, filling the air with a busy hum. Gradually a knot of bees is seen to gather on some bush or tree close at hand, and this knot increases in size until the whole swarm have joined it. If left to themselves, they will remain at rest for an hour or more, when they will again take wing and go off in a 'bee-line' to some chimney top or decayed tree that has previously been decided upon. As soon, however, as the cluster is complete, the bee-keeper proceeds to skep the swarm. This he does by placing a straw-skep over it, and allowing the bees to crawl up of their own accord; or he may hold the skep under the cluster, and give the branch a sudden shake, when almost every bee will fall into the skep. He then shakes them into the bar-frame hive, which is either left till evening where the cluster has gathered, or is removed at once to its permanent station. Previous to swarming, the rearing of half a dozen, or more, of young queen bees had been commenced. Eight or ten days after the swarm issues, the most advanced of these queens comes to maturity, and issues forth from her cell. Her first impulse is to destroy the remaining royal grubs. If the hive be of sufficient strength to swarm a second time, the workers keep guard over the cells, when the newly-hatched queen takes flight with a second colony. Unless increase of stock is aimed at, second swarming should be avoided, and when they do occur, they should be returned again to the hive.

'Ringing' or 'tanging' the bees is an old custom not yet extinct. On the issue of a swarm, the owner proceeded to make hideous noises by beating on old pans and the like, thinking thus to prevent the bees from leaving his garden. The practice is so entirely ineffective, that some have thought it was originally meant merely to proclaim the ownership of the swarm.

Artificial Swarming.—As has been already noticed, a swarm left hanging in its original cluster will go off and establish a home for itself. The hives during the swarming season should therefore be carefully watched. To avoid the necessity of watching for swarms and the chance of eventually losing them, methods of artificial swarming are now practised by all advanced bee-keepers. This is a process easily accomplished, especially with the bar-frame hive. An empty hive is placed on the site of the hive to be swarmed, which is itself moved aside. The frames of bees are lifted out and examined one by one until the queen is discovered, when the comb on which she is found is placed in the empty hive. One or two brood-

combs are also removed and placed along with it. The hive is filled up with empty bars and covered up as before. Empty bars take the place of those removed from the old hive, which is taken to a new situation in the garden, when the work is complete. All the bees on wing during the operation, as well as the old bees in the swarmed hive, will make their way to the new hive on the old site. In the case of swarming from a straw-skep the principle is the same, but the method of procedure is somewhat different. As the combs cannot be removed in the search for the queen, the bees must be driven from them. In order to do this, a warm day is chosen when the bees are busily engaged at work. The hive must first be quieted as already described, when it is inverted, and an empty skep of about the same size is placed over it at an angle of 45°, touching it at a point where the combs converge. The skeps are held together at this point by a skewer pushed through their edges, while the empty one is supported by another skewer in front. Then a gentle and regular rapping with the palms of the hands is commenced on the sides of the hive, when the bees begin to run, slowly at first until a buzz arises, and they rush in a long stream into the empty hive. A sharp watch should now be kept for the queen, who will be seen running up with the other bees, and after a little experience, she will rarely pass without being noticed. The new hive with the swarm containing the old queen is then placed on the old stool, and the parent hive is removed to a new site.

Feeding.—A hive should have at least 20 lb. of honey stored for winter use. After the season is over it may be found that the supply is deficient, and as bees should never be fed during the winter months, the quantity should be made up before cold weather sets in. If fed in autumn, a strong colony will easily store away a quart of sirup in 24 hours, and the whole winter supply may be thus given in a few days. A good feeding sirup may be made by dissolving 4 lb. of cane-sugar in 2 pints (40 oz.) of water over a gentle fire. A tablespoonful of vinegar should be added to prevent the sirup from recrystallising in the combs. One-fourth of a pint of this given daily will be found to be sufficient. Gentle feeding in early spring is also frequently advisable. The simplest method of feeding is to fill a jar or squat bottle of sufficient size to hold one day's supply. Over this a piece of linen should be tied, when the bottle may be inverted over a hole cut in the quilt.

Getting the Honey.—In olden times, the invariable method pursued in this country of taking the honey was by allowing the bees to work at will in small straw-skeps until the close of the season, when they were destroyed by sulphur fumes. This has almost everywhere now given place to a more humane method of management. The method usually adopted by advanced bee-keepers is what is known as 'extracting.' This method is only possible in the movable comb hive. A box of equal dimensions to the body of the hive, and filled like it with bars, is placed above the bars. The quilt is removed, and its place is taken by a sheet of 'excluder zinc'—i.e. zinc with slits cut of sufficient width to let the worker bees pass freely, but effectually to bar the progress of the queen. The upper story is thus kept free from brood, and the honey got is pure. When this box is filled, it is removed, and an empty one is put in its place. The capping of the cells is then cut off, and the bars are put into a machine known as the 'extractor.' This is a large cylinder containing wirework cages, that may be set in rapid rotatory motion. The centrifugal force throws out the honey, and the empty combs are replaced on the hive, to be

again filled by the bees. By this method of working, the bees are saved the labour of comb-building, and large harvests of honey may be secured. As much as 400 lb. of surplus honey has been taken from a single hive in this way. It should be noted that heather-honey, being of a thicker consistency than flower-honey, cannot be extracted in this way. Another method is to fill the upper story of the hive with boxes of thin wood known as 'sections,' placed side by side. The sections are usually made to contain 1 or 2 lb. of honey, and are fitted, like the bars, with guides of comb-foundation. The advantage gained here over the old method of producing large supers, is that the surplus-chamber, like the hive, may be enlarged or contracted at will, while the sections may be removed as they are filled, and their place supplied by empty ones. The honey, too, is put into the market in a form much more convenient for use. The quantity of honey that may be taken from a hive differs with the locality as well as with the season. In a good season, a populous hive will yield from 50 to 100 lb. of comb-honey, besides laying up a sufficient store to keep them through the winter, while, if the extracting system be followed, double this amount is easily got.

The honey of various regions is flavoured by the flowers predominant in the districts where it is gathered—heather, rosemary, lavender, orange-flowers, white clover, bass-wood, lime-tree; that gathered from the flowers of some kinds of African Euphorbia and other plants is poisonous. In Scotland, it is not unusual to transport the hives in the flowering season to the neighbourhood of heathery tracts. The honey most famous in the ancient world was that of Mount Hybla in Sicily, and Mount Hymettus in Attica. Supplies are imported into Britain from various quarters; but it is to the United States and Canada that we must turn for bee-farming on the largest scale, and California, especially Southern California, is the paradise of bee-keepers. In 1880 there were said to be 700,000 hives in the United States, kept by 35,000 persons, of whom 5000 were professional bee-keepers. Some bee-keepers have from 2000 to 3000 hives; and as much as 700 lb. of honey has been obtained from one hive. The most improved hives, honey-extractors, artificial combs, and comb-foundations are in general use. In California the bees swarm in March or April, and the taking of the honey begins about the 20th May. See ADULTERATION, HONEY, WAX.

Beeberu. See GREENHEART.

Beech (*Fagus*), a genus of Cupuliferae (q.v.). There are about fifteen species, all forest-trees of great beauty. The COMMON BEECH (*F. sylvatica*) forms whole forests in many parts of Europe. It

is one of the stateliest of our forest-trees, and rivals the oak in its dimensions and outline. Its bark is smooth, of a gray colour; and it is remarkable for the frequency with which hard wooden knobs—abortive buds—occur in it. Grass does not grow readily under the shade of the beech, but some rare plants are almost peculiar to such situations. The beech thrives best in light soils; and does not send its roots deep into the ground. The wood is very

Branch of Common Beech :
a, flower; b, fruit.

hard and solid, but brittle; and when exposed to the open air, very liable to rot and to be worm-eaten. It is therefore not adapted to the purposes of the house-carpenter; but when kept always under water, it is very durable, and is accordingly employed in the erection of mills, and for weirs, sluices, &c. It is extensively used by cabinet-makers in the making of chairs, tables, bedsteads, &c., and by turners in making wooden bowls, ladles, butchers' trays, and many other articles of everyday use. It is used also in the manufacture of carpenters' planes and other tools. Berkhamstead, Hertfordshire, is noted for its trade in beech turnery-ware. The wood is also employed by wheelwrights, cartwrights, and coachbuilders. It is much used in France for making *sabots*, being preferred for that purpose to any other, except walnut-wood, on account of its not readily absorbing water. It is regarded as being superior to that of most other trees as fuel, and the green wood is generally preferred to the dry, as it burns more slowly. It also makes an excellent charcoal. The ashes yield a large amount of potash of superior quality. The leaves are sometimes used for making mattresses, and the male catkins in packing. The raspings of the wood are used in the preparation of vinegar; the bark is sometimes employed for tanning where oak-bark is scarce, and also for making pyroligneous acid. The beech bears lopping well, and is often planted for hedges. Beechmast, when fresh, has a sweet taste, like that of a walnut. A volatile, narcotic, poisonous principle called *Fagin* is found in it, but more in the rind than in the kernel. This poisonous principle is, however, easily dissipated by drying; after which the kernels are in some countries ground into flour. Pigs, poultry, and cattle have been long known to thrive and fatten on it, but it is injurious to horses. It yields to pressure a great quantity of oil which is said to be equal in flavour to olive oil, and keeps longer sweet; it is used for many domestic purposes and in the arts. The marc left after the oil is expressed is given as food to swine, cattle, and poultry, but swine are apt to be attacked by a distemper called *garget* when they are fed exclusively upon it. Cocoa is sometimes adulterated with beech-mast.

Beeches from 90 to 100 feet high, with stems from 12 to 22 feet in girth, are not rare in Britain. The finest one in the kingdom is at Newbattle Abbey, Midlothian. It is 95 feet high, and girths 37½ feet at 1 foot, 21½ at 5 feet, from the ground, while the spread of its branches is 350 feet in circumference. The beech is not, in general, found in Europe north of 59° lat., although it occurs two degrees farther north in Scandinavia. It is found in the temperate parts of Asia and in North America; the WHITE BEECH of the latter country being generally regarded as the same species. In gardens and pleasure-grounds a variety is very frequently to be seen of which the leaves have a red colour or purplish-brown, and is named the PURPLE or COPPER BEECH. The same colour appears also in some degree in the narrower and longer leaves of the RED BEECH of North America (*F. ferruginea*), which forms extensive forests; and its wood, which is of a reddish colour, is more valued than that of the White Beech.—Two species of beech are found on the mountains of Java; four are natives of the more elevated parts of the south of New Zealand; several belong to the south of South America. The genus is, in fact, more characteristic of the colder latitudes of the southern than of the northern hemisphere. *F. betuloides* is the 'myrtle-tree' of the mountains of Tasmania—a large tree with small, evergreen, leathery, serrate leaves. The same species is the evergreen beech of Terra del Fuego, where it forms forests of which the dark green foliage contrasts strikingly in winter with the dazzling snow. The wood makes tolerable planks, and is carried to the treeless Falkland Islands for roofing houses. *F. antarctica* ascends higher on the mountains about the Strait of Magellan. It has deciduous leaves, and much resembles the common beech. *F. procera* grows in the Andes of Chili, and attains a majestic size. It is a valuable timber-tree.

Beech-drops. See CANCER ROOT.

Beecher, one of the most remarkable families that America has produced since the settlement of the continent. Its founder settled in 1638 at New Haven, Connecticut; and there LYMAN Beecher, an eminent divine, was born October 12, 1775. He graduated at Yale College in 1797, and became a Presbyterian minister. He preached at East Hampton, on Long Island, from 1798 till 1810; at Litchfield, Connecticut, from 1810 till 1826; and in the latter year was called to a pulpit in Boston, with the avowed purpose of counteracting the growth of Unitarianism, which, under the influence of Channing and others, was then rapidly advancing. Of an energetic and positive character, Beecher was always among the foremost to combat what he considered the evils of his time. As early as 1806 he attacked the practice of duelling, in a sermon suggested by the killing of Alexander Hamilton by Aaron Burr, and he laboured earnestly in the cause of temperance in the early days of that reform. In 1832 he became president of Lane Theological Seminary, near Cincinnati, Ohio, a position which he held for twenty years. Though a professed Calvinist, he was arraigned for heresy by the extremists of his faith, but was acquitted by the presbytery, and thenceforth was a recognised new school leader in the controversy which rent the Presbyterian Church into old school and new school factions. He resigned the presidency of the seminary in 1852, and died January 10, 1863. In 1864 was published his autobiography and correspondence, edited by his son. Mr Beecher was the father of thirteen children—seven sons (all of whom became clergymen) and six daughters.

CATHERINE ESTHER, the eldest child of the family, was born at East Hampton, on Long Island, September 6, 1800. In early life she became engaged to a Professor Fisher, of Yale College, who was lost by shipwreck, and she never married. From 1822 to 1832 she was principal of a seminary in Hartford, Connecticut, and subsequently devoted her energies and her pen to the advancement of female education. She wrote numerous volumes, principally relative to the needs and duties of women. She died May 12, 1878.

HARRIET ELIZABETH (Mrs Harriet Beecher Stowe), author of *Uncle Tom's Cabin*, was born in Litchfield, Connecticut, June 14, 1811. In her childhood she received careful training both at home and at the academy of her native village, and she early developed a fondness for writing—often upon the most abstruse subjects—that amounted almost to a passion. It is recorded that when twelve years of age, at an annual exhibition of the academy, she surprised her friends by the production of an essay on the negative side of the question, 'Can the Immortality of the Soul be proved by the Light of Nature?' On leaving the academy she joined her sister Catherine at her school in Hartford—first as pupil and afterwards as teacher. There she remained until the appointment of their father to the presidency of Lane Theological Seminary, when the two daughters established a school at Cincinnati, Ohio, adjoining the slave-state of Kentucky. Here Harriet saw much of the practical workings of the institution of slavery, and became acquainted with many of those scenes and incidents which she afterwards so graphically described in her anti-slavery writings.

In 1836 she married the Rev. C. E. Stowe, a theological professor in Lane Seminary, with whom she subsequently removed to Brunswick, Maine, and in 1849 she issued her first work, *The Mayflower, or Sketches of the Descendants of the Pilgrims*. In 1851 she engaged to contribute a story to *The National Era*, an anti-slavery paper published at Washington (the seat of government), the result of which was the production of *Uncle Tom's Cabin* (unquestionably the most famous novel ever issued in America), which, besides being translated into many foreign languages, has been repeatedly dramatised and represented upon the stage with great success. Probably more than a million copies of this work have been printed in English. Within a year 120 editions, or over 300,000, were issued and sold in America; in four months she had received \$10,000 in royalties. *Sunny Memories of Foreign Lands* (1854) was a charming volume of letters from Europe. Of *Dred, a Tale of the Dismal Swamp* (1856), 100,000 copies were sold in Britain in four weeks. Mrs Stowe died at Hartford, Conn., 1st July 1896.

Other works were *The Minister's Wooing* (1859); *The Pearl of Orr's Island* (1862); *Agnes of Sorrento* (1862); *Oldtown Folks, a Story of New England Life* (1869); *Lady Byron Vindicated* (1870), a work which, even had its monstrous allegations been true, should never certainly have seen the light; *My Wife and I* (1871); *Paganine People* (1878), &c. See the *Life*, compiled (before her mind became clouded) from her letters and journals, by her son (2 vols. 1890).

HENRY WARD BEECHER, was born at Litchfield, Connecticut, June 24, 1813. He graduated at Amherst College, Massachusetts, in 1834, studied theology under his father at Lane Theological Seminary, preached for two years at the small town of Lawrenceburg, Indiana, and in 1839 was called to Indianapolis in the same state, where he laboured for eight years, acquiring considerable reputation as a pulpit orator, and becoming

noted also for his active interest in the secular questions of the day. He early became identified with the anti-slavery movement of the country (then in its infancy), and introduced into the synod, amid much opposition, a resolution declaring it to be the duty of every clergyman to preach against slavery, and followed this act by a course of sermons depicting the horrors of the institution as it then existed in the United States. In 1847, on the organisation of Plymouth (Congregational) Church, in Brooklyn, New York, he accepted the pastorate, and practically ignoring formal creeds, announced his determination to preach the gospel of Christ, and to do battle in the causes of temperance and anti-slavery. An immense congregation was attracted by his ministrations, and during his subsequent career of forty years (less a few months) he laboured in this chosen field with an almost unparalleled earnestness. He aided in establishing *The Independent*, a politico-religious journal, to which he was for nearly twenty years a prominent contributor. He favoured the free-soil party in the presidential campaign of 1852, and denounced the repeal of the Missouri Compromise (1854); and in the contention which followed between the pro-slavery and anti-slavery factions in the settlement of the territory of Kansas, he openly counselled the meeting of force with force if necessary in the protection of the Free State settlers in their rights. He was an ardent supporter of the republican candidates in the presidential contests of 1856 and 1860, and on the breaking out of the civil war, his church raised and equipped a regiment of volunteer soldiers for service in the field. Some rest to his overtaxed powers becoming necessary, he visited Europe in 1863, and on his return to England from the Continent, he delivered addresses on the condition of his country to crowded meetings, often of unsympathetic auditors; and it is not unreasonably claimed by his friends that he did much at this time towards convincing the British public that his government would ultimately triumph. On the close of the war in 1865, Mr Beecher became an earnest advocate of reconciliation between the two sections on the broadest ground of charity and goodwill. He even alienated, by his liberal course, many of his former political friends, among others the editor of *The Independent*; and his connection with that journal ceased. Later (1870) he assumed the editorship of *The Christian Union*, the circulation of which increased in one year from 3000 copies weekly to over 30,000. Of the charge of adultery with a member of his church, preferred against him in 1875, it is enough to say that one trial resulted in the disagreement of the jury; whilst another before an ecclesiastical council was decided in Beecher's favour. The decade of active usefulness which followed served to restore to the great preacher a large measure of public confidence and esteem. He visited Great Britain in the summer of 1886, delivering numerous addresses, and on his return resumed his pastoral duties, in the active discharge of which he died of apoplexy, March 8, 1887.

Of his published writings, the principal are *Star Papers* (1855), first published in *The Independent*; *New Star Papers* (1858), republished under the title of *Summer in the Soul*; *Thoughts as they Occur*, contributed to the *New York Ledger*, and republished, under the title of *Eyes and Ears* (1864); *Lectures to Young Men* (1844; revised ed. 1850); *Aids to Prayer* (1864); *Norwood, or Village Life in New England* (1867); *Lecture-room Talks* (1870); *Yale Lectures on Preaching* (3 vols. 1872-74); *The Life of Jesus the Christ* (2 volumes, 1871-91), &c., besides many separate sermons and addresses. See his *Life*, by Joseph Howard, jun.

(1887), and the largely autobiographical *Authentic Biography*, by his son and son-in-law (1888).

Beechey, SIR WILLIAM, R.A., born at Burford, Oxfordshire, in 1753, entered the Royal Academy as a student in 1772, and devoted himself chiefly to portrait-painting. In 1793 he was elected an associate of the Royal Academy; and in 1798 he received the honour of knighthood, and was made a Royal Academician, for his picture of the Cavalry Review in Hyde Park by George III., which is reckoned his best work. Beechey now received the patronage of the royal family and court. Among his portraits are those of Lord Nelson, Sir William Hamilton, Lord St Vincent, Lord Cornwallis, John Kemble, and Mrs Siddons. Beechey was not a painter of the first rank, but his portraits are generally characterised by easy attitude and naturalness of expression. He died at Hampstead, 28th January 1839.—His son, FREDERICK WILLIAM, born in London in 1796, entered the navy at the age of ten. In 1818 he took part under Franklin in a scientific voyage of polar discovery; and the services he rendered with his pencil during this voyage gained a grant of £200 from parliament. In 1819 he was engaged in another arctic expedition under Parry; and in 1821 rendered further important services to science by his exploration of part of the north coast of Africa, of which the results were published in 1828. In 1825 he received a commission to proceed by the Pacific Ocean and Behring Strait to the Polar Sea, in order to communicate, if possible, with Franklin, who was to make the journey overland from North America. The explorers did not meet, although at one time they were within 150 miles of each other. Beechey returned in 1828, and in 1831 published a narrative of his voyage. Port Clarence and Port Grantley, to the south-east of Cape Prince of Wales, were discovered by him in 1827. He was made Rear-admiral of the Blue in 1854, having in 1843 published his *Voyage of Discovery towards the North Pole*. He died 29th November 1856.

Bee-eater (*Meropidae*), a family of birds nearly allied to kingfishers. Numerous forms occur, widely distributed in Africa, India, Moluccas, and Australia, and are well known for their bee-eating propensities and bright plumage. The Common Bee-eater (*Merops apiaster*) very rarely occurs in Britain,

Common Bee-eater (*Merops apiaster*).

but is an exceedingly abundant summer visitor in Southern Europe. Even Aristotle speaks of its ravages among the bees, which the bird seizes on its swallow-like flight, or by watching beside the hives. They excavate long holes which honey-comb the banks of rivers like the Don and Volga.

These nests are sometimes 10 feet deep, and the wearing away of the rather long bill testifies to the amount of labour which they expend to secure the safety of the young. These are often seen sunning themselves at the openings of the holes, tumbling back when alarmed by the approach of reptilian or other enemies. When the flowers wither and the bees cease to work, the birds migrate southwards, and breed again in Africa, where Livingstone has described their excavations on the banks of the Leeba. Their bright, predominantly green plumage is often used to decorate ladies' hats, and they have further some practical importance on account of their destructiveness to bees, which is compensated to some extent, however, by their ravages among wasps and other insects. The Hottentots watch their flight in order to find the bee-nests.

Beef. See CATTLE, FOOD.

Beef-eater (*Buphaga*), a small genus of African perching birds, nearly related to the starlings. The name Ox-pecker is more accurately descriptive of their habit of feeding on the larvae of gadflies and the like, which they find on the backs of cattle, camels, rhinoceroses, and other large animals. Livingstone notes how the sharp eyesight of the South African Buffalo Birds (*B. africana*) make them useful sentinels to the cattle herds, and the same has been observed in regard to the rhinoceros. Their habit of devouring the insect pests, which they generally do without irritation to the infested animals, is evidently convenient and pleasant both for themselves and the cattle.

Beef-eater, a term now applied jocularly to certain functionaries belonging to the Yeomen of the Guard (q.v.), who, ever since the time of Henry VII., at whose coronation they made their first appearance, 30th October 1485, have formed part of the train of royalty, attending the sovereign at royal banquets and other state occasions. The Tower Warders are a distinct corps from the Yeomen of the Guard, and had their origin in the reign of Edward VI., when fifteen of the Warders were sworn in as Extraordinary Yeomen of the Chamber. They received liveries like the Yeoman of the Guard in ordinary, but are distinguished from them by the absence of the cross-belt. The costume has varied somewhat during the four centuries; a slight alteration was made in 1858; and in 1885 a cloth hat was given to be worn with the undress uniform of the Tower Warders. Their costume has had much to do with their attractiveness to sight-seers. The word has of late been usually regarded as a corruption of *buffetier* (Fr.), or *beaufetier*, one who attends the buffet or sideboard. It would thus be an instance of what Latham calls 'foreign words simulating a vernacular origin;' like *sparrow-grass* for *asparagus*, ancient for *ensign*. But Skeat holds that *beef-eater* is simply *eater of beef*, a servant or dependant, and quotes *eat*ers (from Ben Jonson) and *powder-beef lubbers* used in a similar sense. See T. Preston's *Yeomen of the Guard* (2d ed. 1887).

Beef-tea is a light and pleasant article of diet, obtained from the flesh of the ox. It is best made as follows: A pound of lean beef is cut into small pieces and placed in a closed jar with a pint of cold water; after an hour the jar is allowed to stand for another hour in a pan of gently boiling water; the contents are then strained through a coarse sieve. A much more concentrated beef-tea may be made by placing the meat in a jar without water and simmering it as above for two or three hours. Salt is then added according to taste. Either of these processes removes from the meat almost all its salts and extractive matters, with a proportion of its albumen and gelatine.

Beef-tea is popularly supposed to contain all the nourishment of the meat from which it is made. This is a great mistake: for though the substances which give the beef its flavour are extracted, far the larger part of the nutritious albumen and gelatine remain in the tasteless and hardly digestible residue: more complex processes are required to obtain highly nutritious extracts from meat. It is, however, of great value in the treatment of invalids, for the nutritious elements which it does contain are, so far as they go, in a digestible form; it is, moreover, a pleasant stimulant, a relish which may enable a sick person with poor appetite to eat other food with enjoyment, and a suitable vehicle for the administration of more nutritious material, for example, some of the easily absorbed 'peptones' or 'infants' foods' in the market. It must always be borne in mind that beef-tea alone has not a high value as a food, and that the increased sense of strength and well-being often following its administration is due to a stimulating more than to a nourishing effect, and is therefore transient and sometimes harmful. Moreover, in some diseases, particularly gout and kidney-disease, it is usually injurious. Mutton, treated in a similar manner, yields a broth or tea which is not so easily digested, and is hurtful to persons of weak stomach, especially if the fat be not skimmed off from the liquid. A knuckle of veal affords a similar broth or tea: but it is not so light as beef-tea, and, moreover, gelatinises on cooling. A broth or tea prepared from a young chicken is, of all decoctions of animal matter, the most readily digested, and is specially suitable for invalids, where great irritability of the stomach exists.

Beef-wood. See CASUARINA.

Beehive Houses. The beehive plan of construction is a primitive method of throwing a roof of dry-stone masonry over a chamber of the same. In building with hewn stones and mortar, a stone-roofed chamber would be vaulted on the principle of the arch; but in primitive building with undressed stones and without mortar, the method was adopted of setting inward each successive course of the upper part of the side walls, until the space to be

in the chambered cairns or barrows of Britain and Ireland; and as these have been shown by their contents to belong to the stone age, it is therefore the earliest method of constructing a roof of which we have extant evidence in the British Isles. It is also the usual style of the basement chambers of the Brochs, or so-called 'Pictish towers' of Scotland, which belong to the iron age. In the early Christian period, many of the small churches and oratories of the Celtic Church in Scotland and Ireland were still constructed in the same primitive manner; and the dwellings of the monks in early Celtic monasteries have been termed 'beehive houses,' from their being almost invariably built of dry stone and roofed in this manner. In some districts of Ireland, as in Kerry, the remains of beehive houses, called by the country-people *cloghams*, are still abundant. They are not connected with ecclesiastical sites, but seem to have been the common dwellings of the inhabitants at some time probably not extremely remote, but now unknown. O'Flaherty, mentioning the *cloghams* of West Connaught in 1684, describes them as buildings of stone, brought to a roof without any manner of mortar to cement them, some of which would hold forty men on their floor, and which were so ancient that nobody knew how long ago any of them were made. In the Western Isles of Scotland there are many remains of beehive houses of quite recent date. Captain Thomas saw forty or fifty in a limited area of the island of Lewis in 1857; and Dr Mitchell records in 1880 that not more than from twenty to thirty were then inhabited. These, however, were not the permanent dwellings of the people, but the huts of their summer shielings, erected usually on grassy spots in the glens to which they proceed with their cattle, and remain making butter and cheese in July and August, 'during which time,' says Captain Thomas, 'they dwell in these circular stone-roofed houses called *bothan*, or in timber-roofed ones called *airidhena*.' The *bothan* are seldom larger than 10 feet in diameter; a row of stones is placed across the interior for a seat, on one side of which is the fire, and on the other the sleeping place. Many of the older ones, however, have several chambers, each with its beehive roof. Captain Thomas considers them a survival of the Scotic type of the earliest artificial dwelling. Beehive constructions of various types and periods are described and figured in Dr Arthur Mitchell's *Past and Present*, Dr Joseph Anderson's *Scotland in Early Christian and Pagan Times*, and Lord Dunraven's *Sketches of Irish Architecture*. Huts of beehive shape, but of light materials, are used by various savage peoples.

Beelzebub ('god of flies'), the form of Baal worshipped by the Philistines at Ekron. The Greeks also had Zeus 'Apomyios' or 'Myiagros' ('dispenser of flies'), doubtless a god of flocks and herds. As the heathen deities were all regarded as demons by the Jews, the name Beelzebub became, in course of time, commonly applied to the chief of evil spirits, and in this sense it is employed in the Gospels. The more correct reading of the word is *Beelzebub*, variously explained as 'lord of the dwelling,' 'lord of the dunghill.' See BAAL.

Beer and Brewing. Beer is the popular term applied to an infusion of malted barley which has been boiled with hops and afterwards undergone fermentation. Like other alcoholic beverages, it possesses great historical antiquity and interest. Egyptian manuscripts written at least 3000 years before the Christian era show conclusively that even at that primitive period the manufacture of an intoxicating liquor from barley or other grain was extensively carried out in Egypt. Pliny also records in his time the regular use of a fermented drink, made from 'corn and water,' in

The larger Beehive Cell in Skellig Mhichel.
(From a Photograph by Lord Dunraven.)

spanned was so reduced that it could be covered in by a single stone, or by several stones laid lintel-wise, side by side. This method of constructing a stone roof is found in many varieties of prehistoric structures. It is the usual style of roofing the chambers

all the districts of Europe with which he was acquainted. In Britain, little was known about beer before the Roman conquest, the beverages then being chiefly mead and cider. With the improvements in agriculture, however, which followed the conquest, we learn that ale was made from barley and other grain, although differing somewhat from its latter-day representative. By the aid of biology and chemistry, the product has vastly improved within recent years; and it has become the general beverage of many of the leading nationalities of the world. In considering the various processes employed in the different stages of its modern manufacture, it may be best to take them up in their natural sequence, as the ordinary reader may in that way be the better able intelligently to follow. Firstly, then, as the crude basis in brewing, we have to consider the barley. The barleys used at the present day are very various, and many countries are called upon to contribute to the contents of the modern brewer's barns; but practically speaking, the barleys used may be divided into two distinct classes—viz. heavy barleys, weighing from 54 to 58 lb. per bushel, and light barleys, weighing from 48 to 52 lb. They have all their special virtues or drawbacks according to the vicissitudes of the seasons—some being specially serviceable one season, and utterly useless another. And of course the skill of the brewer is displayed in selecting and blending each season in his mash-tuns only those barleys that produce a malt yielding the proper proportions of extractive matter that will, after being boiled with hops and fermented, give him a sound, bright, and delicately flavoured beer. This is a matter requiring somewhat elaborate practical and chemical experimental preliminary examination (beyond the ordinary judgment of experience), and it is impossible to enter into it in detail here. One remark may, however, be made generally on the choice of brewing barleys; they should be thoroughly well and equally ripened, well 'got' or harvested, and as far as possible presented to the brewer in the perfect husk or envelope with which nature has furnished the kernel. Ancient and modern modes of thrashing and dressing to a greater or less extent damage both the husk and the kernel, and thus at the very threshold introduce one of the causes of disease. Whenever the grain is broken or bruised, it is liable to be attacked when moist by a variety of moulds which lead to more or less serious disaster.

Having selected the barley, the next thing is to prepare it for the mash-tun, or in other words to transform it into malt. This is done by steeping the barley in water in iron cisterns with a perforated draining gutter in the bottom, for a period of from 72 to 96 hours, according to the condition and character of the barley. The water is run off and renewed every 24 hours in order to keep it sweet and fresh. At the end of the steeping period the water is thoroughly drained off, and the barley cast on to the malting floor, and the process of germination watched with the greatest care. In cold weather the saturated grain is kept from 12 to 18 inches thick for the first 24 or 36 hours. As soon as the growth begins, the 'floor' is thinned out, and the thickness must now be regulated by the rate of growth. The changes of atmospheric temperature have to be constantly noted and compensated for by the thickening or the thinning of the 'floors,' and by letting in or shutting out the colder or the warmer outside air. In all well-regulated malt-barns provision is made for an abundant supply of fresh air, as this is essential to sound and regular growth; and when under proper control, it should be judiciously used to equalise and regulate

the growth of the malt. The use of further water on the floors is necessary in order to stimulate the growth, and this is applied by means of a sprinkling-pan, which is simply a species of watering-pan specially designed for the purpose. In this way a gentle or a heavy shower can be administered to the floor as the maltster may think fit. The process of growth goes on for various periods according to the varying temperature and the kind and quality of the barley. In mild weather about ten days may be stated as the average period from steep to kiln, and in cold weather about twelve days. It is, however, important to have the growth gradual and at a comparatively low temperature, because the chemical change or modification that is brought about by the progress of the aërospire (the future blade) over the cruder material of the kernel is the main object of malting; and if this growth is irregular, or allowed to proceed at too high a temperature, then you have the apparent requisite growth without the corresponding work done. Lighter barleys malt and mature faster than the heavier varieties; and the maltster must study the peculiarities of each variety, and work it accordingly.

The malt being satisfactorily finished on the floor, is then removed to the drying kiln (fig. 1),

Fig. 1.—Malt-kiln :

A, upper drying floor; B, under or finishing floor.

where it is kept for three or four days. Kilns are large square buildings varying in height (according as they are single or double storied), with wire-cloth floors, an ample ventilator on top, and an open fire underneath. Most kilns have only one drying floor; but those of recent construction have two floors, the one seven feet above the other. The fresh malt is laid on the top floor (A) for two days, and then lowered to the under or finishing floor (B), to be succeeded on the top by another fresh supply. The advantage and economy of this method will be apparent, and American brewers are adopting three stories instead of two. The heat is gradually applied until the moisture is driven out of the malt, when the temperature is further increased to 170°–190° F., and after being kept for some hours at that point, the malt is removed to the store to await the summons to the mash-tun. The chemical change that takes place during malting is not great, and the operation may therefore be regarded as the preliminary preparation of the

barley for the revolutionary changes in the mash-tun. The next step is to crush the malt in order to make it amenable to the action of hot water. This is usually done by an ordinary pair of steel rolls (E, fig. 2); but in large breweries two pairs are at work, the one crushing the small, and the other the large grains. The crushed malt, or 'grist' as it is now called, is then conveyed by means of an elevator (F) to hoppers (G) placed in a position to command all the mash-tuns (I) in the mash-house. At the bottom of each hopper is a shoot, placed immediately above the external mixing or mashing machine (H), which consists of a short cylinder, with a shaft having a number of attached arms and screw-propeller revolving inside. There are two apertures at one end for the admission of the hot water and the grist respectively, while the other end is left open to allow the free exit of the mash. When the operation of mashing commences, the hot water is turned on, and the shoot of the hopper partially opened to allow the grist to come in contact with the water, and the mixture or mash passes out into the tun with the consistency of ordinary porridge. In most breweries there are also internal mashing-machines in the mash-tub. These machines serve the same purpose as the external ones, and consist of a series of rakes worked by means of a shaft under the tun. When mashing is conducted by means of the internal arrangement alone, then the whole or greater portion of the mashing liquor is run into the tun, the machinery set in motion, and the grist gradually added.

Great importance is attached to the 'initial' temperature of the mash, but there are so many considerations which regulate its range (within reasonable limits), that they cannot be entered into in detail. They are briefly quality, kind, and condition of malt, variety and character of beer to be brewed, and the relative thickness or thinness of mash. It is also a general practice to raise the temperature of the whole mass by the admission of hot liquor at the bottom of the tun a short time after the first mash. Speaking generally, about 150° F. is the average striking temperature with the English and Scotch systems. As soon as the mash is finished, the tun is carefully covered up to prevent as much as possible any loss of heat during the period of infusion. And now an extraordinary transformation process goes on inside the mash-tun through the action of a soluble albuminoid or unorganised ferment in the malt, known as diastase, which possesses the power of converting the modified starch of the malt into malt-sugar and dextrine. Although this change or conversion takes place very rapidly, the mash is usually allowed to stand for about two hours, when the taps at the bottom of the tun are opened to allow the extract to

drain off through the perforated false bottom. The operation of 'sparging,' or washing out the extract, now proceeds at the same time as the running off, and is accomplished by means of a rotatory copper pipe (K), perforated on alternate sides, which distributes a gentle and continuous shower of hot water equally over the surface of the mash. When the sparging is finished, the waste liquor in the tun is drained off, leaving behind the well-known feeding material, draff or brewer's grains. The extract, or 'wort' as it is

now termed, is received into an intermediate vessel (L), and either pumped or run direct into the coppers (M), where it is briskly boiled for about two hours with its allotted portion of hops.

Hops.—It is the female flower of the plant that is used by the brewer, and it is difficult to say how long he has appropriated it to his special purpose. It was certainly known in very ancient times, and Pliny mentions in his *Natural History* that the Germans preserved ale with hops. Coming to our own country, there is no doubt the hop was known in England before the Conquest, and passages in contemporary writers show that some use was made of the plant by the Saxons in their primitive process; but the date of its practical introduction for brewing (judging again from contemporary writers) was most probably the middle of the 15th century. The hops exert a purifying, a preservative, and an aromatic influence over the wort. The tannin precipitates the excess of albuminous matter, thus ridding it of a certain source of after trouble, while other constituents of the hop in different ways play their preservative part.

From the copper, the wort passes into the hop-back or drainer (N)—a vessel provided with a perforated false bottom, through which the wort

drains on to the cooler, leaving the hops behind in the back. In many breweries the wort is forced by means of a pump (P) from the drainer to the cooler, but this is not necessary when the site and construction of the brewery allow of the wort running by gravitation from the mash-house to the fermenting-worm. The cooler (Q) is a large shallow vessel constructed of fine metal plates, but since the introduction of improved refrigerators, it does not occupy the important place it once did in the breweries of this country—those good old times when brewers had to sit up all night waiting on the evening breeze to perform the functions of the cold-water pipe. Coolers are now much reduced in size, and in some cases are abolished altogether, the wort being run direct from the hop-back through the refrigerators. Refrigerators (R), though varying slightly in form, are all similar in principle. They consist of a series of flat copper tubes or pipes, with cold water circulating through them, while the hot wort circulates outside, and gets gradually cooled as it passes each alternate set. The wort and the water circulate in opposite directions, so that the gradually cooling wort is always meeting with colder water in its passage through the refrigerator. As the wort passes directly from the refrigerator to the fermenting-tuns (S), the flow must be regulated in accordance with the temperature at which you wish to 'pitch' or start your fermentation. The pitching heat is a point of pre-eminent practical importance, as upon it depends, to a great extent, the success of the fermentation that is to ensue. Every fermentation must be kept within certain bounds, and if the initial control is lost, it can never be altogether recovered. From 55° F. for strong beers, up to 61° F. for weak beers, is a fair range of pitching temperature, while the quantity of liquid yeast added to start the fermentation varies from 6 lb. to 1 lb. per barrel according to quality of beer and vitality of yeast. Immediately on the addition of the yeast the fermentative action is set up, and in a few hours the surface of the liquid is covered with a brownish cream, which gradually increases in volume owing to the rapid multiplication of the yeast-cells. These are buoyed up by the escaping gas until the yeasty head rises to a height of 2 or 3 feet, and carbonic acid gas is given off in great abundance. During the first 12 hours the fermentation proceeds slowly, but after that period the vigour increases, accompanied by a rapid rise in temperature, and correspondingly rapid decrease in the specific gravity of the liquid. After about 40 hours the contents of the fermenting-tun are generally run off into some intermediate vessel to regulate and control the finish of the fermentation. All settling vessels are provided internally with a series of pipes called attempterators (T), through which cold water can be passed in such quantity as may be necessary to cool the beer to its normal racking temperature. In Burton the beer is pumped into large casks called 'unions,' while in Scotland it is generally finished in large square vessels called 'settling'-squares (U).

When the fermentation is finished and the beer so far 'settled' or freed from suspended yeast, it is racked into casks, and stored in the cellars until ready for consumption. This period varies with the character and kind of ale; local mild ales being fit for use in about a week; pale ales, in two to four months; while strong and export ales require ten to fifteen months to fit them for the market. With all export and pale ales, a quantity of the finest hops is added to the casks as they are filled. This greatly improves the flavour and the keeping and clearing qualities of the beer. Various theories have been advanced at

successive periods in explanation of the phenomenon of fermentation, but that of Pasteur holds the field. Recent researches in molecular physics doubtless give some support to Nägeli's molecular-physical theory, but it is far from satisfactory. On the other hand, Pasteur's beautiful theory of alcoholic fermentation is at once scientific and rational. He has clearly proved that it is a vital phenomenon caused by the living yeast-cell, out of contact with *free* oxygen, attacking and breaking down the maltose molecules of the wort to satisfy its own requirements. In further support of this theory, Pasteur and Muntz have proved beyond question, that the cells of plants (morphologically similar to yeast-cells), when deprived of the requisite supply of *free* oxygen by being placed in an atmosphere of carbonic acid gas, give rise to the ordinary products of vinous fermentation. The cells attack the sugar already formed in the plant, depriving it of its oxygen, and producing alcohol and carbonic acid in the same way as yeast does in any saccharine solution. See FERMENTATION.

The yeast-ferment belongs to the lower order of Fungi, and when added to beer-wort, it assimilates the free oxygen, then attacks the sugar, decomposing it into alcohol and carbonic acid, with a number of minor products, such as succinic acid, glycerine, &c. The simple form of rearrangement may be thus represented:

Pasteur's researches have further enabled him to expose and to explain the insidious and destructive working of some of the wild ferments and bacteria which occasionally play such havoc with the produce of the brewery.

Nothing has yet been said regarding the water-supply of the brewery, and although it comes in last, it is by no means the least important element in the process. Absolutely pure water is essential to the successful brewing of all beers, and for high quality keeping ales it is also necessary that it should possess considerable permanent hardness. This is the case with the Burton and Edinburgh wells, hence their product is deservedly held in high repute.

We have not in describing the mashing said anything about the substitutes that are used to partially replace the malt extract, but since Mr Gladstone's Inland Revenue Act of 1880, they have become so general as to decidedly deserve mention. They consist either of a preparation of raw grain, or some variety of brewing sugar. The raw grain consists of specially prepared rice or maize-meal, and while such a substitute may be used in the mash to the extent of 5 to 10 per cent. for ordinary beers, it cannot be used with the same degree of freedom for fine pale or export ales. The ordinary brewing sugars, manufactured mostly from rice and maize-meal by the action of heat and dilute acid, are perhaps the safest substitutes, provided a proper brand is secured: but nothing has yet been brought before the scientific brewer to take the place of malt extract which can compare or compete as a 'substitute' with O'Sullivan and Valentin's 'Dextrine Maltose.' It is manufactured from raw starch, like the sugars, by the action of dilute acid, but the transformation is checked just at the moment when the relative proportions of dextrine and maltose are similar to those found in normal malt wort. The moderate use of *genuine* substitutes for malt does not in any way diminish, but rather tends to promote the purity of the beer, and the prejudice against them is altogether misguided and mistaken. In some countries barley is discarded altogether in many cases; the native grain being used in its stead, producing naturally a

'native' beer, and differing somewhat from our idea of what a beer should be like. Thus in Japan a popular drink (*Saki*, q.v.) is made from rice; in South America and India, from maize; while in some parts of Africa the millet seed is the source of the intoxicating beverage. See also *AVA*, *PULQUE*.

Varieties of Beer.—There are various technical terms used to distinguish the different kinds and qualities of beer. Thus, 'Table Beer' is a beer of light gravity, and as its name signifies, was meant originally for general table use; though still greatly in favour, it has been largely replaced by other varieties, notably Pale Ale. 'Pale Ale' is a highly hopped beer made from the very finest selected malt and hops, while 'Mild Ale,' or as it is called in Scotland 'sweet ale,' is of greater gravity or strength, and is comparatively lightly hopped. There is also a difference in the mode of fermentation. Pale ales may be allowed to attenuate very low, but the mild ales must be brewed and fermented so as to keep them at a higher finished attenuation. This gives them a rounder, fuller flavour, while the moderate proportion of hops makes the mildness or sweetness more pronounced. 'Porter' again is a black beer, and requires to be differently manipulated in the mash-tun from any of the varieties just mentioned. It is necessary to have in the mash a mixture of pale amber and roasted malts in the proportion requisite to give the desired flavour and colour, and having achieved this, porter thereafter goes through almost the same process as ordinary ale. Stout is the name given to better-class porter, in other words, a stout or strong porter.

In the foregoing epitome of the process of brewing as generally practised in this country, mention of special systems—such as the skimming and Yorkshire Stone Square—has been purposely omitted, as likewise has any reference to the vatting and blending of stouts. These are subjects for a book on brewing; but a sentence may be added regarding lager beer, which, although only manufactured in a few isolated instances in Great Britain, is now growing rapidly in favour in America and in nearly all the warm climates of the globe.

The difference between the manufacture of lager and ordinary beer lies in the system of fermentation, the type of yeast used, and the manner of storage. The fermentation is carried on at a temperature from 20° to 25° F. below the ordinary average of this country, and the yeast, in place of rising to the top, falls to the bottom of the fermenting-square. It is essentially a 'bottom' yeast fermentation as opposed to the typical 'top' fermentation of English and Scotch beer, while the yeast-cell is rather smaller and more irregular. In consequence of the low temperature the fermentation is naturally more prolonged, occupying from ten to twenty days, and the type of alcohol differs from that produced at a higher temperature, being considered physiologically more beneficial. Some years ago, great stress was laid on the German system of mashing called the 'thick mash,' which consisted of boiling or cooking a portion of the mash, and running it back and remixing it with the portion left in the tun; but it is now found perfectly possible to brew the finest lager beer with a slight modification of our own mashing method. As soon as the lager fermentation is finished, the beer is stored in large vats in cellars kept at a temperature of from 38° to 42° F. In about four months' time the beer is ready for consumption, when it is racked into casks, and each day's supply sent out to the customers fresh from the brewery every morning.

In consequence of the low temperature at which it is fermented and stored, lager beer holds in solution a large quantity of carbonic acid gas,

hence its crisp refreshing palate flavour and fine creamy condition.

With the passing of Mr Gladstone's Inland Revenue Act of 1880, a somewhat important change has come over the brewing industry of the country. Previous to the passing of that act the tax was levied on the malt in lieu of the beer—in other words, on the raw material instead of the finished product. Since October 1880, however, brewers can be charged duty either on the beer produced or on the materials used, and if the beer produced from say 40 qrs. of malt is less than the excise authorities presume should be got from that quantity of material, then the brewer has to pay on the quantity mashed, and not on the barrels in the fermenting-tun. The standard which the Inland Revenue have fixed is 18 gallons of beer of 1057° specific gravity for every 42 lb. of malt mashed. Many of the smaller brewers, without proper plant appliances, are placed at considerable disadvantage under the new act, owing to their inability to obtain the presumptive extract from the lighter varieties of malt; and owing to this and other causes they are decreasing in number year by year, as the following figures, which must be of general interest, show. In the year ending September 1880—the last year of the malt-tax—there were 21,223 persons licensed as brewers for sale in the United Kingdom, while in the following year—the first year of the beer-tax—there were only 17,110, or a decrease of 4113 licensed brewers in one year. In 1886 there were only 14,166 licensed brewers. But in spite of the great decrease of licensed brewers, the quantity of beer produced in the United Kingdom remained practically the same. In 1893 the number of brewers licensed for sale had further decreased to 10,143, while the quantity of beer made had increased. The vigorous ferment called by the Japanese name of Taka Koji, and derived from the fungus *Eurotium oryzae*, has been used as a substitute for yeast. There are treatises on brewing and malting by Black (1875), Steel (1878), Faulkner (1884), Stopes (1886), and Moritz and Morris (1891); see also Mathers, *The Microscope in the Brewery* (1889), and Biekerdyke's *Curiosities of Ale and Beer* (1886).

The following table shows the consumption (in gallons) of beer per head in various countries:

	Production. Consumption.	
	Barrels.	Gals. per head
Belgium.....	5,800,000	36.00
United Kingdom.....	27,500,000	26.27
Germany.....	25,500,000	20.00
United States.....	22,000,000	14.14
Denmark.....	600,000	11.65
Holland.....	900,000	8.46
Austria-Hungary.....	7,700,000	7.10
Norway.....	376,000	6.36
Switzerland.....	440,000	5.87
France.....	5,500,000	5.21
Sweden.....	537,000	4.20
Canada.....	370,000	3.17
Russia.....	2,000,000	0.54
Italy.....	94,000	0.13

With reference to the above table, it should be mentioned that in the case of Germany the figures refer to the whole German empire. The consumption varies enormously in the different states, being as much as 40 to 50 gallons per head in Württemberg.

Beer Acts. See LICENSING ACTS, INN.

Beer-money was a peculiar payment to non-commissioned officers and soldiers in the English army. It was established in the year 1800, at the suggestion of the Duke of York, and consisted of one penny per day for troops when on home-service, as a substitute for an issue of beer and spirits. It continued as an addition to the daily pay until 1873, when, the stoppages for rations having been

abolished, the opportunity was taken to consolidate beer-money and pay proper.

Beer'sheba, now BIR-ES-SEB'A ('well of swearing,' or 'well of seven'), so called because of the covenant Abraham entered into here with Abimelech the Philistine king, which he ratified with an oath and a gift of seven ewe lambs. Beersheba was situated on the southern border of Palestine, about 52 miles SW. of Jerusalem, and formed the limit in that direction of the Israelitish dominion. In the 4th century A.D., it was the seat of a large village, with a Roman garrison; some of its churches were standing in the 14th century. A heap of ruins now marks the site of the village. Two of its wells are still almost always full of water. The shafts are of round masonry, worn with the water-drawers' ropes, and they have no parapet.

Beestings (technically *colostrum*) is the term applied to the first milk yielded after delivery. It differs not a little from ordinary milk, and generally appears as a turbid, yellowish, viscid fluid, similar to soap and water. When examined under the microscope, it is found to contain, in addition to the ordinary milk corpuscles (see MILK), peculiar conglomerations of very minute fat granules, which are hence known as colostrum corpuscles. The chief chemical differences between beestings and milk are, that the former is very deficient in casein and proportionately rich in albumen, and that it contains nearly three times more salts than the latter. It is probably this excess of salts that usually causes it to exert a purgative effect upon the new-born offspring, and thus to remove the Meconium (q.v.) which has accumulated in the fetal intestine.

Beeswax. See WAX.

Beeswing (so called from its appearance), a filmy crust of tartar formed in port and some other wines after long keeping. See WINE.

Beet (*Beta*), a genus of Chenopodiaceae (q.v.). The species are not numerous; they are mostly biennials, with smooth, ovate, stalked root-leaves, and tall, leafy, flowering stems. They are natives of the temperate parts of the Old World. The Common Beet (*B. vulgaris*) is a native of the shores of the Mediterranean, but is now in very general cultivation both in fields and gardens, chiefly for the sake of its large succulent roots, which are used as food for man and cattle, and from which also sugar is extracted (see SUGAR). The variety known as Red Beet is the most esteemed for garden cultivation. Of this there are many sub-varieties, distinguished by the form of their roots, some being tap-rooted or carrot-like, others turnip-shaped, and by the depth of purple or crimson colour they all more or less exhibit. The darkest crimson coloured are the most highly esteemed, partly

Common Beet.

on account of their more pleasing appearance when cooked, but also because they contain a larger amount of mucilage and saccharine matter than the lighter tinted kinds. Roots of medium size are preferred to those that are larger. It forms a favourite pickle, is used in salads, and is also very agreeable as a boiled vegetable when properly dressed. It is more nutritive and whole-

some than any other cultivated root except the potato. When deprived of the greater part of their juice by pressure, the roots may be used as a substitute for malt. They have also in times of scarcity been ground and mixed with flour for bread-making in continental countries. The seed is sown late in spring that the plants may not produce flowering stems the first year, which would render the root fibrous and useless.—Mangold-wurzel (q.v.), so valuable as a field-crop for food of cattle, is, in general, regarded as merely a larger and coarser variety of the common beet, in which the red colour is comparatively little exhibited.—The White Beet of our gardens (*B. cicla* of some botanists) is now also generally supposed to be a mere variety of the common beet, with little or no red in its roots or leaves, and a comparatively slender root. It is cultivated for the sake of its leaves, which are used in the same manner as spinach, and form an excellent substitute for it, especially in summer, when heat and drought deprive it of its essential succulence. The leaf-stalks and midribs of the leaves, especially of a variety in which these parts are unusually developed, are blanched and dressed for table in the same manner as sea-kale, and named *Chards*. Sea-beet (*B. maritima*) grows wild upon the shores of Britain, and differs from the common beet in its perennial root, its partly prostrate stems, and other characters. The leaves are used for food in Ireland, as are also those of *B. Bengalensis* in the East Indies.

The process of making beet-sugar will be treated at SUGAR. The development of this manufacture in France, Austria, and Germany has enormously extended the cultivation of beet-root, and the importations of beet-sugar have seriously affected the sugar trade in Britain. The quantity of beet-root sugar made in Europe in the season 1850-51 is estimated at 160,000 tons; in 1884-85, it was 2,510,000 tons, which is 2½ times the total imports into Europe of tropical sugar in 1851. The importation of tropical sugar has not merely not increased in the same proportion, but has in some places actually diminished. The growth of the manufacture has been especially rapid in Germany, where in 1863-83 the production of sugar increased by 338 per cent. The production in Austria doubled in 1872-82; in France the growth has not been so rapid, though manufacture and exportation are stimulated by bounties. The comparative production of sugar from cane and beet and other relevant figures will be found at SUGAR, Vol. IX. pp. 789-790. In Germany, by improved processes, nearly 11 per cent. of sugar is obtained from a given weight of beet-root; 9.26 cwt. of beet produce 1 cwt. of sugar. It should be noted that a large proportion (from ⅓ to ⅔) of the saccharine matter of the sugar-cane is not saccharose, but glucose, which is not available for sugar; whereas in beet there is little or no glucose at all, nearly the whole of the saccharine matter being saccharose.

The question of growing beet for sugar-making has been repeatedly raised in Ireland, and two unsuccessful attempts have been made to establish factories for the purpose. Irish beet-root has been grown containing from 10 to 14 per cent. of sugar. For sugar-raising, beet should be sown early, and not taken out of the ground till November; and close-growing of the roots favours the production of sugar.

Beet-fly (*Anthomyia betæ*), a dipterous insect which sometimes infests crops of beet or mangold-wurzel. In spring the very small eggs are laid in patches on the under surface of the leaves. The hatched maggots, which are about a third of an inch long, devour the soft parts, and after about a month of voracious life become pupæ, which are

usually buried in the ground. In about a fortnight the flies appear, measuring about half an inch from tip to tip of expanded wings. There seem to be two or more broods, and the last set of pupæ remain as such during the winter. It has not been noted as a frequent pest in Britain, but did great damage in 1880. Dressing with guano, soot, and especially superphosphate, was found efficacious. The genus includes a large number of forms. Compare CABBAGE-FLY, TURNIP-FLY, POTATO-FLY; and Miss Ormerod's *Injurious Insects*.

Beethoven. LUDWIG VAN, one of the greatest of musical composers, was born at Bonn, December 16, 1770. The family was originally Dutch, from near Louvain. The father was a tenor singer in the elector's band at Bonn, at £25 a year, a man of irregular life and severe temper. The mother appears to have been of no account. Ludwig's teachers were his father, Pfeiffer, and Van den Eeden and Neefe, both court-organists; also Ries for violin, and Zambona for letters. He was soundly and solidly taught, except in counterpoint, but was not precocious. Thus his first symphony dates from his 31st year, an age at which Mozart had written forty-five, including many of his greatest works. He joined the band, April 26, 1783, as accompanist, and on June 27, 1784, was made second organist. In 1787 he paid a short visit to Vienna and played to Mozart. About this time he began to be intimate with Count Waldstein and with the Breuning family, at Bonn. In 1788 the elector remodelled his band, and formed a national opera, at which the best works were performed. Beethoven played the viola in it, and Reicha, Ries, and Romberg were members. On November 20, 1789, the father's salary was transferred to Ludwig, and he became head of his family. In 1790 he wrote a cantata on the death of Joseph II. (not discovered till 1884). In the Christmas of that year he first saw Haydn. In 1791 we first hear of Beethoven's extempore playing, and he is already using the sketch-books so characteristic of him. In July 1792 Haydn again passed through Bonn, and warmly praised and encouraged him; and very shortly afterwards the elector sent him to Vienna to study under that great composer. He left Bonn in November, at the end of his twenty-second year. His compositions up to this date were unimportant; the cantata, two string Trios (ops. 3 and 8), two easy Sonatas (op. 49), the two piano Rondos (op. 51), are all that can be said to survive. But though thus backward, his character and his musical knowledge were fast maturing and consolidating. He displays the obstinacy, the humour, the absorption, the power of attachment of his later life; the best people of Bonn are devoted to him, and all believe strongly in his future. He is already one of the finest extempore players of the day.

In November 1792 he is established in Vienna, taking lessons in counterpoint from Haydn, and, during Haydn's absence in London, from Albrechtsberger; also from Schuppanzigh on the violin. He learned also from Salieri and E. A. Förster. In July 1795 he published the three Trios (op. 1); and on March 9, 1796, the three piano Sonatas (op. 2); the two piano Concertos in B flat and C were composed before April 1795; *Adelaide* was written that year; the Sonata in E flat (op. 7) was published October 1797; that in D (op. 10, No. 3), September 1798, &c.

Henceforward his works are composed in regular succession:

1800. Six String Quartets; C minor Concerto; Symphony No. 1; Septet; *Prometheus*, *Mount of Olives*.

1801. Quintet in C; Sonatas ops. 26, 27, 28.

1802. Symphony No. 2; Sonatas, piano and violin, op. 30. His deafness becomes serious. Letter called 'Beethoven's Will,' dated October 6.

1803. *Kreutzer* Sonata; piano Sonatas, op. 31.

1804. *Eroica* Symphony; *Waldstein* and *Appassionata* Sonatas.

1805. *Fidelio* produced November 20 (Overture 'No. 2'); piano Concerto in G; three Quartets, op. 59. This year the French occupied Vienna.

1806. *Fidelio* (2d version, Overture 'No. 3'); Symphony No. 4; violin Concerto.

1807. Overtures *Coriolan* and *Leonora* 'No. 1'; Mass in C.

1808. Symphonies 5 and 6; piano Trios in D and E flat; Choral Fantasia. This year brought an offer from King Jerome Bonaparte to direct his music at Cassel, but it ended in a guarantee from the Archduke Rodolph and Princes Lobkowitz and Kinsky to pay him an annual income of 400 paper florins—at that time worth £210.

- 1809 was the year of Aspern and Wagram, and the second French occupation of Vienna; but composition went on, and we find the piano Concerto and Quartet in E flat, the Sonatas in F sharp and E flat (op. 81a), and many small works. Haydn died May 31.

1810. *Egmont* music; the Quartet in F minor, besides some small military pieces.

- 1811 produced the piano Trio in B flat; the music to *King Stephen*, and the *Ruins of Athens*. The latter part of this summer he spent at Teplitz.

1812. Symphony No. 7, May 13; second visit to Teplitz, Carlsbad, and Franzensbrunn; meeting with Goethe; returns by Linz, where he completed the 8th Symphony, and two pieces for trombones, to Vienna; Sonata for piano and violin, op. 96, completed and played at Vienna before the close of the year.

1813. Battle of Vittoria, June 21; composition of the *Battle Symphony*, produced with Symphony 7 at a great concert, December 8. Summer spent at Baden.

1814. Symphony No. 8 produced February 27; *Fidelio* rewritten, and given May 23; Sonata, op. 90, August 16; Overture, op. 116, October 4; Congress at Vienna; Cantata, *Der glorreiche Augenblick*, November 29; *Tournament* music (still in MS.), November 23. Lawsuits with Maelzel and with Count Kinsky's heirs—the beginning of troubles.

Up to this date, notwithstanding the drawbacks consequent on his deafness, which was now total, he seems on the whole to have enjoyed life. The next period was a far more painful struggle.

1815. Troubles still continue. Quarrel with Stephen Breuning. Death of his brother Carl, November 15. Compositions few; Sonatas, piano and 'cello, op. 102; *Mercetille*; Sonata, op. 101; arrangement of Scotch songs.

1816. *Liederkreis* composed, April. Lawsuit with Carl's widow; appeals; terrible troubles. Lawsuit with Professor Lobkowitz; pension reduced to £110; Philharmonic Society buys Overtures *Ruins of Athens*, *King Stephen*, and op. 115, for £78, 15s. Last appearance in public, April 20.

1817. Nothing but worries and troubles. Beginning of *Choral Symphony*.

1818. Piano sent by Broadwood, February. Sonata, op. 106, and Mass in D both begun; 9th Symphony continued. Summer and autumn at Mödling; anxieties about his nephew.

1819. At Mödling; work and worries still continue.

1820. Appeal decided in his favour (January), and his nephew goes into his charge. Sonata, op. 109. Mass proceeding.

1821. Sonata, op. 110, December 25.

1822. Sonata, op. 111, January 13; Mass completed March 19; at Baden, Overture, op. 124; 9th Symphony proceeding. Reconciliation with Stephen Breuning.

1823. Symphony proceeding; 33 Variations, op. 120; Symphony finished at Baden, September 5. Visit of Weber and Benedict, October 5; Rossini-fever at its height, and neglect of all other music;

- proposal to write an opera, and worries thereon; subscriptions to Mass unsuccessful.
1824. Mass in D and 9th Symphony performed May 7. Quarrels with his best friends. Autumn at Baden. Quartet, op. 127, completed October. On returning, moves into Schwarzschanerhaus, where he died; illness in the winter.
1825. At Baden from May 2 to October 15. Quartets in A minor, op. 132, and B flat, op. 130, completed.
1826. C sharp minor Quartet, op. 131, written; young Carl banished Vienna for misdeeds; they visit Johann Beethoven at Gneixendorf; last Quartet, op. 135, composed October 30; present finale to B flat Quartet composed November; returns to Schwarzschanerhaus at Vienna, December 2; Beethoven takes to bed, which he never again leaves; receives £100 from Philharmonic Society, also Handel's works from Stumpff of London. Makes acquaintance with Schubert's music.
1827. He died March 26, at a quarter to six P.M., during a thunderstorm, and was buried on the 29th at the Währinger Friedhof, outside Vienna.

Beethoven's music has not yet become at all antiquated. *Fidelio* still fills the theatre to overflowing, and a performance of his Mass in D is still the great ambition of conductors. His symphonies are now more played than ever before, and form the staple of all orchestral concerts. The same is equally true of his quartets and trios. His sonatas are not only the test of the greatest executants; but they are the indispensable material by which thousands of humble piano students are taught; and yet no one ever wearies of them. The reason of this is partly the nature of the thoughts, apart from the extraordinary energy and the stern conciseness which animates and controls them, and which are synonymous with his name; they are always noble, simple, unpretentious, and yet containing a depth of meaning which is ever fresh; they are also free from affectation or passing triviality; they seem to reach down to the common basis of humanity—to that which lies at the bottom of every heart; and thus his melodies often have a surprisingly fresh and modern effect, as if made yesterday. At the same time they are not vulgar; they have the geniality and common-sense of Haydn's thoughts, but are of a loftier and wider cast. In his music, as in life, the serious and the humorous mix, and set off one another, as they do in the works of Shakespeare. He must not be thought of merely as a musician. He himself has told us that he always worked to a picture or a scene. His music was as truly the expression of the mental image and emotion as is the language of the greatest poet or dramatist; it was never an exercise in mere technicality. Even the complicated fugues of his latest sonatas are as full of meaning as the other and less scientific movements. In some cases the 'subjects' which form the texts of his music are abrupt and individual beyond all precedent, in others they are steeped in heavenly beauty and feeling, in both instances because they are the representatives of corresponding emotions; and in all cases the world, which began by scoffing or shrinking, has approved them. The contrasts and varieties in the instrumentation and setting of his thoughts are truly wonderful; it is as if he had his hearers constantly in his eye, and was always thinking how his thoughts could be presented in some new light, and how the attention could be best kept up until the end of his discourse. His last works, those composed during and after the period of trouble and distress, which reached from 1815 to 1820, have something of their own—something rarely if ever found in the earlier years, and unknown in his predecessors. They seem to breathe more than beauty, energy, or variety of sound, and in some mysterious way to mingle morals with music, and to lift us into a higher

region and a keener air than any other compositions. But this cannot be explained; and no one who has felt what is meant will ask for an explanation. Another point is the extraordinary variety of the music. Not only each work, but each movement is entirely different from all the others of the same name or class; and here again is a point of resemblance to Shakespeare.

This pre-eminence is not the result of any sudden impulse or impromptu effort: on the contrary, it was the effect of enormous care and labour. Fortunately, many of his sketch-books are preserved, and they enable us to see how insatiable he was in altering and rewriting his work till he got it into exactly the proper shape, and the oftener rewritten the more spontaneous does it become in the end. There is hardly a bar in his music of which it cannot be justly said that it has been written fifteen or sixteen times. His best themes often first appear in a mere commonplace form, but by repeated alterations they are brought to their present natural and eternal shape. And when he has found the proper vehicle for his thought, he is never weary of repeating it, until, as in the Pastoral Symphony, the music seems to consist of the continual reiteration of a few pregnant ideas. His music was the expression of his great mind, and no pains were too great that could make it more noble or truly refined, or could add to its beauty. And the same attention is shown in everything. No one before was so careful to mark the intended pace, or the changes of expression, or the minutest *nuances*, or to see that his publications were correctly printed.

Beethoven was no doubt an innovator; but he was so as every original thinker must be who wants means to express what no one before has thought; only that in his case the thoughts were far greater and the expression far more varied than elsewhere. His early works can often be hardly distinguished from Mozart, and it is only by degrees that the nature of the man shows itself. (The Sonatas op. 7 and op. 10, No. 3; the Coda of Finale to Symphony No. 2, are some of these early steps.) But his innovations were legitimate, never for their own sake. He worked on the old lines till he found that he needed to enlarge or modify them. Thus he enlarged the introduction and the coda; he introduced episodes in the 'working-out'; he changed the minuet into the scherzo; he multiplied the key-relations of the movements; he introduced the chorus into the finale of a symphony; he invented the 'cycle of songs'; he put variations on a new footing, which has been adopted and extended by his successors; he initiated the modern use of 'programme-music'; and everything that he did was more serious, more thoughtful, and therefore more permanent than any one else's. At the same time, it is pure music of the grandest, most touching, and beautiful sort. While adhering to the framework which seems essential for all art that is to appeal to the race and not to cliques of individuals, he shows that such framework need be no impediment to the most passionate, most personal, most universal ideas. Other men have followed the road which he opened, and have carried still further his extensions of form; but no one has done it with the same powers, or with such unabated freshness, or has met with such wide recognition by all hearers and all minds of whatever tendencies or constitution. We often hear of 'Beethoven's three styles.' It means that he began writing as his predecessors wrote; that by degrees his own genius asserted itself and made his music stronger, broader, more deeply coloured, more beautiful, than music had ever been before; and that lastly his deafness, his poverty, the troubles of life, the

approach of the end, brought a peculiar and unapproachable sentiment into his thoughts.

He accepted the orchestra as he found it, for the trombones were nobly employed by Mozart, and the double bassoon formed a part of the orchestra at Bonn, and was also used by Haydn. But there is much of the highest interest in his employment of the various instruments. Every one is sooner or later immortalised—the drum in the 4th Symphony, and in the E flat Concerto; the horn in the *Eroica*, 7th and Choral Symphonies; the bassoon in the 8th Symphony; the trombones in the *Benedictus* of the Mass in D, and so on. The orchestra of the 2d Symphony is obviously founded on that of *Figaro*, but in the *Eroica* all that is changed.

He raised the *status* of musicians as much as he had enlarged the bounds of the art. Mozart and Haydn had been salaried lackeys, but Beethoven would be no man's servant, and by his mere independence, and some secret spell which counteracted all his discourtesy, compelled the highest classes of Vienna to treat him as an equal. No one before or since can show such a list of dedications of his works, and all were apparently purchased by regard and not by money.

His character was simplicity itself; falsehood was absolutely foreign to his nature, and he carried truth and sincerity into *brusquerie*, and often into shocking rudeness. The books are full of stories of this which cannot be given here. And yet, so great was the influence of his personality, that those to whom he was rudest were fondest of him. Princes, cardinals, high-born beautiful ladies, women like Rahel, and men like Goethe, were devoted to him, and put up with every unpunctuality and every incivility. Varnhagen von Ense, after several weeks' intimate communication, 'found the man in him much stronger than the artist.' His simplicity sometimes became credulity, blinded him to real facts, and made him often unfair and harsh. This showed itself unjustifiably towards his relations, and towards many of his best and truest friends. Such conduct must have been greatly due to his deafness, his sensitive nature, and his absorption in his music, and he was always ready to confess his error: he was full of the deepest feeling, and there is something wonderfully touching in his devotion towards his nephew, one of the meanest, most graceless scamps on record; but on whom, partly because he was left to him, partly because of his craving for affection, he lavished all his tenderness. His nature and his deafness drove his goodness inwards, and we must look to his music, and to the mystical aspirations with which he salutes God in the sunrise, or the beauty of the woods, for the deeply religious feelings of his great heart.

Though a Catholic by birth, and dying in that faith, he had little formal religion. And yet a more deeply religious mind never existed. In every trial his thoughts flew upwards, and his note-books are full of the most passionate ejaculations. God was to him the most solemn and intimate reality, whom he saw and welcomed through all aspects of nature, and in every mood of joy and sorrow. Living in a profligate city, and in a time of the loosest morals, and himself singularly attractive to women, his name is not connected with a single *liaison* or scandal. 'It is one of my first principles,' says he, 'never to stand in any relations but those of friendship with another man's wife.' Again, 'O God! let me find the woman who is destined to be mine, and who shall strengthen me in virtue.' He wrote no second opera because he could get no libretto of the virtuous, elevating cast which he thought essential, and which alone he would consent to set.

Beethoven was 5 feet 5 inches high, very broadly

and firmly built; his head large, and the hair black, thick, and abundant. His eyes were dark in colour, very bright, and peculiar. His voice was rough on occasion; but when he was touched it had a light tone which was peculiarly affecting.

For the details of Beethoven's life, and the best books regarding him, the reader is referred to the American A. W. Thayer's *Beethoven's Leben* (3 vols. Berlin, 1866-87), written in German and not translated; to the present writer's *Dictionary of Music and Musicians*, and to his *Beethoven and his Nine Symphonies* (1896).

Beetle, the name of an order of insects technically known as Coleoptera. There are indeed some insects popularly called 'beetles' which are not Coleoptera, and some Coleoptera which would hardly be termed 'beetles,' but for practical purposes the two words are synonymous. They have generally the usual four wings, but the front pair form hard and horny covers for those behind, which alone are used in flight. The feelers or antennæ have only a few joints; the jaws or mandibles are almost always biting organs like those of the Cockroach (q.v.), and the fourth pair of mouth appendages (second pair of maxillæ) are completely fused together. They go through a complete metamorphosis (q.v.), the young beetles being caterpillar-like forms, usually with six legs, and always unlike the adult. The males are usually distinguishable from the females by differences of size, form, colour, fighting organs, sounds, &c. For general anatomy, see INSECT. There are probably about 100,000 different species, more than twice the total number of backboneed animals, and among these myriads there is, within a small range, such a marvellous diversity of form, colour, size, and habit, that general characteristics are hard to note. About the beginning of this century, Latreille divided this vast multitude into four great groups according to the number of small joints in the lowest part of the leg. But his four divisions (Pentamera, Heteromera, Tetramera, and Trimera) are artificial, and are abandoned by many modern coleopterists, who arrange the host in seventy-five families. It may be said of most beetles that they are strong, voracious insects, acting as 'universal scavengers,' preferring to remain concealed during the day, and only on occasions taking to flight. Their food varies greatly from hard wood to soft fruits, from the carcasses of animals to dung, and a few become parasites. They are found in water and on land, on plants and among stones, burrowing in the ground and drilling holes in wood, in fact in almost every variety of habitat. Fossil-beetles begin to appear in the carboniferous strata, and are often found imbedded in amber. Their practical importance in regard to vegetation, and their numerous interesting peculiarities of form and habit, will be discussed under special articles.

Cantharis.	Glow-worm.	Water-beetle.
Cockchafer.	Ladybird.	Weevil.
Colorado Beetle.		Wire-worm.

Beetling. In some rural districts of Scotland the peasantry, when they have not ready access to a mangle, beat clothes, newly washed and dried, with a wooden mallet on a flat stone, and the operation is called beetling. The same term is applied to a finishing process in the manufacture of linen, and also of some kinds of cotton goods. Just as in the hammering by hand, the object is to fill up and give a finish to the cloth by flattening its surface. It is done by the rising and falling of upright wooden stamps, placed close together in a row, with their square butts resting on a roller over which the cloth passes under them. The stamps

are worked by the rotation of a horizontal shaft, acting with tapets, like the cylinder of a barrel-organ.

Linen weft yarns, and especially such as are used for heavy sail-cloth, are also beetled by this machine to soften them. But finer weft yarns of this material are now, instead of being beetled, passed through what is called a *softening machine*, which consists of two pairs of grooved wooden rollers with the requisite driving gear.

Beet-root Sugar. See BEET and SUGAR.

Beets. NICOLAUS, Dutch poet and writer, was born at Haarlem, 13th September 1814, and studied theology at Leyden. After serving at Heemstede, near Haarlem, he was in 1854 appointed to the pastorate of Utrecht, and in 1874 to the chair of Theology there. His poetical works have been collected (4 vols. 1873-81). Through the earlier pieces runs a strong vein of misanthropic sentiment, due probably to Byron, some of whose works he translated into Dutch (2 vols. 1835-37). His prose writings include *Camera Obscura* (13th ed. 1880), a series of tales and sketches of life and scenery in Holland, published under the pseudonym of 'Hildebrand'; they display keen observation and considerable humour. Besides several critical works, he has published in theology, notes on the life of St Paul (3d ed. 1858), and *Stichtelijke Uren* (new ed. 8 vols. 1872).

Befana, a corruption of *Epiphania* (Epiphany), which name in Italy has become personified for children as a toy-bringing old woman called *la Befana*. She is a kind of female counterpart of the Wandering Jew and Santa Claus combined, and is employed as a kind of bugbear to frighten naughty children. According to the popular story, she was busy cleaning the house when the three wise men of the East passed by on their way to offer their treasures to the infant Saviour, and when called to the window to see them, she said she could do so when they returned. They went home by another way, and she has ever since been watching for their return. On Twelfth Night she brings good children toys and sweetmeats, but bad children only find their stockings full of ashes. It was also customary in Italy, on the evening before the Epiphany (5th January), to carry an effigy called the *befana* in procession through the streets amid great rejoicings, but this has fallen greatly into disuse.

Beffroi. See BREACHING TOWER.

Beg, now always BEY ('lord'), a Turkish title, rather vague in its import, and commonly given to superior military officers and distinguished foreigners. In rank it stands between *Effendi* and *Pasha* (q.v.). It is often assumed without any authority, and nearly every young Turkish dandy allows himself to be addressed by the title. 'Beglerbeg,' or, more correctly, *Beilerbegi* ('lord of lords'), is the title given to the governor of a province.

Begas. KARL, court-painter to the king of Prussia, was born near Aix-la-Chapelle in 1794. He painted a great many biblical subjects for churches, as well as several historical pictures and portraits. He died November 23, 1854. Of his four sons, two became known as painters, and two as sculptors.

Begg. JAMES, D.D., born in 1808 at New Monkland manse in Lanarkshire, was educated at Glasgow University, and was licensed as a preacher in 1829. Minister of Liberton from 1835 to 1843, he 'came out' at the Disruption, and thenceforward to his death (29th September 1883) held the neighbouring Free Church of Newington, Edinburgh.

A man of fine presence and vigorous intellect, he distinguished himself by his old-world orthodoxy, his humour and combativeness, and his efforts to improve the houses of the poor. See the Memoir by Professor T. Smith (2 vols. 1885-88).

Beggar. See MENDICANCY.

Beggar-my-neighbour, a game at cards played by two persons, between whom the pack is equally divided. Holding their cards back-upwards, the players lay down a card alternately, till an honour is turned up, which is paid for by the adversary—four cards for an ace, three for a king, two for a queen, and one for a knave. Such payment being made, the winner lifts the trick; but if an honour is laid down during the payment, then the opposite party must pay for that in the same way; and so on, till a payment is made without an honour. The object is to win all the cards in the pack. The game is as old at least as 1777.

Beghards. Societies of laymen under this name first appeared in Germany, the Netherlands, and the south of France in the beginning of the 13th century, and were known in Italy as *Bizuchi* and *Bocasoti*; but they never obtained the reputation enjoyed by the Beguine sisterhood. Towards the end of the 13th century they were commonly stigmatised as *bons garçons*, *boni pueri*, and such contemptuous titles, which expressed the low estimation in which they were held. On account of heretics of all sorts retreating into these half-spiritual communities, they were subjected to severe persecutions after 1367, and were gradually dispersed, or joined the orders of Dominicans and Franciscans. In the Netherlands, where they had preserved a better character than elsewhere, they maintained their ground longer, and were protected by Pope Innocent IV. (1245), in Brussels by Cardinal Hugo (1254), and in Liège by Pope Urban IV. (1261); but their communities disappeared in the 14th century. The most probable origin of our word *beggar*, according to Dr Murray, is none other than the old French *begart*, *begard*, or its synonym, *beguin*, whence the verb *beguigner*, *beguiner*, 'to act the beguin.' If this etymology be true, it serves to show how widely these lay mendicants must have been spread over Western Europe.—See BEGUINES; Mosheim, *De Beghardis et Beguinibus* (Leip. 1790).

Begharmi. See BAGIRMI.

Beglerbeg. See BEG.

Begonia. This genus (which gives its name to a small order of doubtful affinities) contains a

Begonia rex.

large number of species which are cultivated in our greenhouses, partly on account of their usually

rink, unisexual flowers, and partly for their remarkable unequal-sided and often coloured leaves, to which they owe such various popular names as 'Elephant's ears' in the East Indies, or, more poetically, 'Angel's wings' in the Spanish Antilles and Mexico. They are almost all tropical plants; but a small species of *Begonia* ascends the Himalayas to at least 11,500 feet, often growing on the trunks of trees. The leaves and young stems are succulent and acid, and those of several species are used as pot-herbs or in tarts like rhubarb. The roots of some are used in their native countries as astringents, and some of the Mexican species are used as drastic purgatives. According to London, begonias were introduced into Great Britain from Jamaica in 1777, but they were little cultivated till 1840.

Beg-Shéhr, or KERELI GÖL, an extensive mountain lake in Asia Minor, 44 miles SW. of Konia, situated almost 3700 feet above the sea. It is over 30 miles long, and from 5 to 10 miles broad, and contains several islands. Its only visible outlet is a rivulet connecting it with the much smaller lake, Soghla Göl, the waters of which occasionally disappear altogether; and it is evident that a great part is carried off through subterranean channels in the limestone range of the Taurus. On its east and north shores are the towns of Begs-hehr and Kereli.

Beguines (BEGUINE, BEGUTTE), a sisterhood within the Catholic Church, first formed during the 12th century in the Netherlands. The origin of the word is doubtful. It is ascribed by some to a St Begga, who is said to have founded the first sisterhood in 696; by others to a priest named Lambertus le Begues or le Béghue, who founded in Liège, about 1180, a society of pious women who were called by his name. The Beguines were not restricted by vows, nor did they follow the rules of any order, but were united under a superior for the exercise of piety and benevolence, and lived generally in separate small cottages, which, collectively, formed the *Beguinaatium*. Their establishments were often enriched by liberal donations. A church, a hospital, and a house of reception or common entertainment, generally belonged to every community. The sisters were distinguished from the rest of the laity only by their diligence and devotedness, piety, modesty, and zeal for the purity of youthful education. Their most flourishing period was during the 12th and 13th centuries, when they spread themselves widely over France, Germany, and the Netherlands. As the pietists of the middle ages, they were often subjected to persecution by the mendicant orders of friars; but on account of their practical usefulness were long sheltered by the popes and councils as well as by the secular authorities. In the 13th and 14th centuries, through their sympathy with the persecuted Fraticelli (q.v.) and the 'Brethren and Sisters of the Free Spirit,' they were brought under the scrutiny of the Inquisition; and on account of certain immoralities, a synod held at Fritzlar in 1244 required that all candidates must be forty years old before they could enter a society of Beguines. These sisterhoods maintained their position in Germany and the Netherlands longer than in other countries. In Holland, they existed at the close of the 18th century; and in the present day we find here and there so-called *Beguinen-huuser* in Germany; but they are now nothing more than almshouses for poor spinsters. At Ghent, there is still a celebrated institution, the Béguinage of St Elizabeth, containing some 700 sisters, who live in a separate quarter of the town in 103 little brick-built cottages, with 18 convents and 2 churches, arranged in streets and squares within a common

wall, open to the visits of strangers. Living here a life of retirement and piety, the Beguines, in their simple dark dresses, go out as nurses to the hospitals, and perform other acts of kindness among the poor. Though they are under no monastic vow, it is their boast that none is known to have quitted the sisterhood. See BEGHARDS; also Hallmann's *Geschichte der Belg. Beghinen* (Berlin, 1843).

Begum (a feminine form corresponding to *Beg*, q.v.), an Indian title of honour equivalent to 'princess,' conferred on the mothers, sisters, or wives of native rulers. The Begum of Ondh (see HASTINGS, WARREN) is well known in Indian history.

Behaim, MARTIN, a famous cosmographer, was born at Nuremberg about 1459. He early entered into mercantile life, and in 1480 went to Portugal, where he soon acquired a reputation as a skilful maker of maps. In 1484 he accompanied the Portuguese navigator, Diego Cam, in a voyage of discovery along the west coast of Africa, and sailed as far as the mouth of the Zaire or Congo River. In 1486 Behaim sailed to Fayal, one of the Azores, but in 1490 he left Fayal and returned to Nuremberg. There he constructed a large globe, principally from the writings of Ptolemy, Pliny, Strabo, Marco Polo, and Sir John Mandeville. It is still preserved by the family of Behaim in Nuremberg, and is a valuable record of the progress of discovery, though it exhibits little accuracy, even for that date. Behaim again resided in Fayal from 1494 to 1506, and then removed to Lisbon, where he died in the same year.—MICHAEL BEHAIM (1416-74) was a German *meistersinger*, a native of Sülzbach, and by profession a weaver. His poems have been edited by Karajan and others (1843-67).

Beham, two brothers, natives of Nuremberg, and both of them painters and engravers.—HANS SEBALD (1500-50) and BARHEL (1502-40). They are reckoned amongst Dürer's seven followers, the 'Little Masters,' and form the subject of a monograph by A. Rosenberg (Leip. 1875).

Behar, or BAHAR (also spelt *Bihar*), once one of the three *subahs* or provinces under the Nawab of Bengal, now one of the four great provinces of Bengal, occupying part of the valley of the Ganges, comprising the two divisions of Patna and Bhagalpur, and subdivided into 12 administrative districts. Area, 44,186 sq. m.; pop. (1891) 24,393,504. The Ganges divides the province almost into two equal parts; it is watered besides by several of its important tributaries. Among the minerals, the most important are coal, lead, silver, copper, and mica, but these are scarcely worked. European vegetables have been introduced, and succeed well. Of indigenous productions, the chief are rice, wheat, barley, maize, pulse, sugar, cotton, indigo, and tobacco. Oil-seeds, opium, indigo, sugar, cotton, and saltpetre are exported. The cultivation of opium is a government monopoly, with its headquarters at Patna. Over 300,000 acres are under poppy cultivation for this purpose. Upwards of a million sterling is invested in the indigo industry in the different districts. The district is also engaged in the manufacturing of muslins, silks, carpets, blankets, tents, tapes, threads, ropes, paper, glass, cutlery, jewelry, leather, ink, soap, and pottery. The East Indian Railway runs through the entire length of the province, and is now the great commercial highway. Before the days even of Moslem domination, Behar appears to have been the centre of a Hindu empire, which native accounts describe as of matchless splendour, and of fabulous duration. *Kooch Behar* is a native state near Bhotan, under the lieutenant-governor of Bengal; area, 1307 sq. m.;

pop. 602,604. Its capital is also Kooch Behar, or Kuch Behar.

Behar, or **BAHAR**, a town of Bengal, 54 miles SE. by S. of the town of Patna. The original city is nearly deserted, and the present town consists of houses scattered about its remains, and interspersed with fields, gardens, and groves. There are some remains of fine mosques. Behar has a considerable trade, chiefly in rice, European cloth, cotton, and tobacco; while silk, cotton cloths, and muslin are manufactured here. Pop. (1891) 47,723.

Beheading. See EXECUTION, GUILLOTINE.

Behemoth (Heb., plural of *b'hēmāh*, 'beast,' a word of Egyptian origin), the name of a large and strong four-footed beast, referred to once in the Old Testament Scriptures, Job, xl. 15-24. Gesenius proves that the description in the passage is more suitable to the hippopotamus than to any other animal, though the elephant has been suggested by some scholars.

Behistun, or **BISUTUN** (ancient *Baghistan*), the site of an ancient Persian city, 22 miles E. of the city of Kirmanshahan. It is noted for its famous precipitous rock, anciently known as Mount Bagistanus, which on one side rises perpendicularly to the height of 1700 feet. Diodorus relates that Semiramis encamped near the rock, and caused the lower part to be smoothed away and an inscription engraved on it in her honour. This, like many other traditions attached to the mythic queen, is now proved false. The rock bears inscriptions of Darius Hystaspes about 518 B.C. The inscriptions—which are in the three forms of cuneiform writing, Persian, Babylonian, and Median—set forth the hereditary right of Darius to the throne of Persia, tracing his genealogy, through eight generations, up to Achæmenes; they then enumerate the provinces of his empire, and recount his triumphs over the various rebels who rose against him during the first four years of his reign. The monarch himself is represented on the tablet with a bow in hand, and his foot upon

Rock Inscriptions at Behistun.

the prostrate figure of a man, while nine rebels, chained together by the neck, stand humbly before him; behind him are two of his own warriors, and above him, another figure (see cut). The Persian

inscriptions which Sir H. Rawlinson has translated are contained in the five main columns numbered in cut 1, 2, 3, 4, 5. The first column contains 19 paragraphs and 96 lines. Each paragraph after the first, which commences, 'I am Darius the Great King,' begins with, 'Says Darius the King.' The second column has the same number of lines in 16 paragraphs; the third, 92 lines and 14 paragraphs; the fourth has also 92 lines and 18 paragraphs; and the fifth, which appears to be a supplementary column, 35 lines. The second, fourth, and fifth columns are much injured. Sir H. Rawlinson fixes the date of the sculpture at 516-515 B.C. See Rawlinson in *Journal of Royal Asiatic Society*, vol. x.; Oppert, *Le Peuple et la Langue des Medes* (Paris, 1879); and Spiegel, *Die Alt-persischen Keilschriften* (Leip. 1881).

Behm, DR ERNST, a German geographer, was born January 4, 1830, at Gotha, where he died on the 15th of March 1884. In 1856 he became Dr Petermann's chief assistant in editing the famous geographical periodical, *Mitteilungen*, to the editorship of which he succeeded on his chief's death in 1878. In 1872 he commenced, in conjunction with H. Wagner, the useful *Bevölkerung der Erde* (vol. vii. 1882), intended as a statistical supplement to the *Mitteilungen*; and from 1876 he undertook the statistical department of the *Almanach de Gotha*. His more extended writings of this nature are marked by fullness, accuracy, and marked lucidity of arrangement.

Behmen. See BOEHME, JAKOB.

Behn, AFRA, novelist and playwright, was born in 1640, at Wye, in Kent, the daughter of one Johnson, a barber. It is doubtful, then, who was the 'father,' lieutenant-governor of Surinam, with whom as a child she sailed for South America. He died on the voyage out, but Afra reached Surinam, and here made the acquaintance of the slave Oroonoko, who afterwards became the subject of one of her novels. Returning to England about 1658, she married Mr Behn, a merchant of Dutch extraction, but was a widow by 1666. Her personal appearance and vivacious freedom of manners pleased the 'Merry Monarch,' and she was sent as a spy to Antwerp, where she succeeded in discovering the intention of the Dutch to sail up the Thames and Medway. The English court, however, took no notice of her information, a slight which caused the fair agent to throw up state politics in disgust. On her return to England, she became intimate with all the profligate wits as well as the more staid scholars and poets of the time, and devoted herself to literature. Her plays and some of her poems are better than her novels, but all alike are disfigured by impurity of tone; and, in point of intellectual ability, none of her works deserves the high praise lavished on them by Dryden, Otway, and Southerne. She died 16th April 1689, and was buried in Westminster Abbey. Her works were reprinted in 6 vols. (1871).

Behring, or **BERING**, VITUS, a famous navigator, born in 1680, at Horsens, in Denmark. He entered early the newly-formed navy of Peter the Great, and for the ability and daring he displayed in the wars with Sweden, was appointed to conduct an expedition of discovery in the Sea of Kamchatka. Sailing in 1728 from a port on the east of Kamchatka, he followed the coast northward until he believed, from the westward trending of the land, that he had reached the north-east point of Asia. After some years spent in explorations on the coasts of Kamchatka, Okhotsk, and the north of Siberia, he sailed in 1741 from Okhotsk towards the American continent, and sighting land about 58½° N. lat., he followed the coast northward for some distance; but sickness

and storms obliged him to return, and being wrecked on the desert island of Avatela, since called Behring Island, he died there, December 19, 1741. Among the few who escaped, in a boat made from the wreck, was Steller, the naturalist, who has left an account of the voyage (St Petersburg, 1793).

Behring Strait separates Asia from America, and connects the Pacific with the Arctic Ocean. The proof that the two continents were not connected was given by a Cossack named Deschnev, who in 1648 sailed from a harbour in Siberia, in the Polar Ocean, into the Sea of Kamchatka. But his voyage was long regarded by Europeans as a fable, until Behring's (q.v.) expedition in 1728. The strait was explored and accurately described by Cook in 1778. The narrowest part is near 66° lat., between East Cape in Asia, and Cape Prince of Wales in America, where the capes approach within 36 miles; about midway are three uninhabited islands. The greatest depth is some 30 fathoms. Haze and fogs are the normal conditions of the atmosphere.—**BEHRING SEA**, a part of the North Pacific Ocean, commonly known as the Sea of Kamchatka, bounded W. by Kamchatka, E. by Alaska, S. by the Aleutian Islands, and N. by Behring Strait. There are several islands in this sea, and here also fogs prevail.—**BEHRING ISLAND**, the most westerly of the Aleutian Islands, barren and destitute of wood, but an important station of the Alaska fur industry. It has an area of 30 sq. m., and is noteworthy as the place where Behring, the discoverer, was wrecked and died in 1741.

Beilan, a pass in the northern extremity of Syria, on the east shore of the Gulf of Scanderoon, runs across the mountain-range of Amanus. It is the common route from Cilicia into Syria, and gave a passage to Alexander the Great, and afterwards to the Crusaders, into Syria. The town of Beilan (pop. 5000) is situated near the summit-level of the pass, at an elevation of 1584 feet above the Mediterranean Sea.

Beira, a Portuguese province, bounded N. by the provinces of Minho and Tras-os-Montes, S. by Estremadura and Alentejo, E. by Spain, and W. by the Atlantic Ocean. It has an area of about 9222 sq. m., and a pop. (1899) of 1,461,834. The surface is mountainous, and the soil on the plains sandy, and generally far from fertile. The mountain-slopes afford good pasturage for sheep and cattle, and from the hogs of Beira are made the well-known Lisbon hams. The products are corn, wine, honey, oil, flax, and various kinds of fruit. Sea-salt is obtained at the coast. The river Douro waters the whole of its northern, and the Tagus a portion of its southern boundary. Iron, coal, and marble are wrought in small quantity, and mineral springs are numerous. The province embraces the districts of Aveiro, Castello Branco, Coimbra, Guarda, and Vizeu. The capital is Coimbra.

Beira, a small town (pop. 2000) in Portuguese East Africa, near the mouth of the Pungwe (q.v.) River, 12 miles from the point whence the railway to Mashonaland starts.

Beiram. See BAIRAM.

Beirut. See BEYROUT.

Beit is an Arabic word, signifying 'house,' 'abode,' or 'place,' the Hebrew equivalent of which is *Beth*. In both languages it is employed in place-names; thus, in the former, we have *Beit-ul-Haram*, 'the house of the sanctuary,' or 'the sacred house;' and in the latter, *Beth-el*, 'house of God;' *Beth-any*, 'house of dates;' *Beth-abara*, 'house of the ford;' *Beth-ichen*, 'house of bread,' &c. See also BETHESDA, BETHSAIDA.

Beit-el-Fakih, a town of Yemen in Arabia, 50 miles SE. of Hodeida (q.v.). Pop. 8000.

Beith, a small town of North Ayrshire, on the borders of Renfrewshire, 18 miles SW. of Glasgow by rail. Its most notable manufacture is that of furniture in large cabinet-works. The chief building is the Speir School (1887), resembling the old college at Glasgow. Pop. (1881) 4037; (1891) 4795.

Beitullah (Arab., 'house of God'), the spacious building or temple at Mecca, which contains the Káaba. See MECCA and KÁABA.

Beja (the *Pax Julia* of the Romans), a town in the province of Alentejo, Portugal, 101 miles SE. of Lisbon by rail. It has a castle and a cathedral, and manufactures of leather and earthenwares. Among its interesting Roman antiquities, the chief are the south gate and an aqueduct. Pop. 8487.

Bejan, or BAJAN, the name of the first or 'freshman' class in the Scottish universities of St Andrews and Aberdeen, and of old in many continental universities. The word is believed to be derived from the French *bee-jaune*, 'yellow beak,' a term used to designate a nestling or unfledged bird. The levying of *bejannia*, or payments for 'first-footing' by students on entering college, was forbidden by the statutes of the university of Orleans in 1365, and of the university of Toulouse in 1401. The election of an *Abbas Bejanorum*, or 'Abbot of the Greenhorns,' was prohibited by the statutes of the university of Paris in 1493. *Bejanns* is another form.

Bejapur. See BLJAPUR.

Bejar, a town of Spain, 45 miles S. of Salamanca. It has cloth manufactures and an annual fair; and in the neighbourhood is a hot sulphur-spring. Pop. 12,312.

Bek, ANTONY, Bishop of Durham from 1283, took a prominent part in the Scottish wars of Edward I., and held a command at the battle of Falkirk. In 1300 he became involved in ecclesiastical disputes, which lasted till his death on 3d March 1311. He was a prelate of great magnificence and unbounded ambition, but chaste and liberal.—Another Antony Bek (1279–1343) was Bishop of Norwich from 1337; a Thomas Bek (died 1293) was Bishop of St David's from 1280; and a second Thomas Bek (1282–1347) was Bishop of Lincoln from 1342.

Bekaa. See COLE-SYRIA.

Beke, CHARLES TILSTONE, Abyssinian explorer and biblical critic, was born in London, October 10, 1800; received a commercial education; afterwards studied law in Lincoln's Inn, and devoted a great part of his attention to ancient history, philology, and ethnography. The results of these studies first appeared in his work, *Origines Biblicæ*, or researches in primeval history (vol. i. 1834), which was an attempt to reconstruct history on the principles of the science of geology, and which gained him the Tübingen degree of doctor of philosophy. In 1837–38 he acted as British consul in Saxony. His historical and geographical studies of the East led Beke to consider the great importance of Abyssinia for intercourse with Central Africa. Supported only by private individuals, he joined in Abyssinia the party led by Major Harris, and distinguished himself (1840–43) by the exploration of countries lying to the south, previously almost unknown in Europe. He fixed the latitude of more than seventy stations, and mapped about 70,000 square miles of country. He also collected the vocabularies of many languages and dialects. The results of these researches appeared in *Abyssinia* (1845) and in various journals. Having returned to Europe, he excited the attention of geographers by his *Essay on the Nile and its Tributaries* (1847). In 1853 he had become partner in a Mauri-

tius mercantile house, and in 1856 he made unsuccessful attempts at establishing commercial relations in Abyssinia. In 1861 Dr and Mrs Beke journeyed in Palestine; and undertook in 1865 a fruitless mission to Abyssinia, to obtain the release of the captives. In 1870 he was granted a pension on the Civil List. At the commencement of 1874, Dr Beke started for the region at the head of the Red Sea, where he claimed (though his views are disputed) to have discovered Mount Sinai, east of the Gulf of Akabah, and not west as generally supposed. He died at Bromley, Kent, July 31, 1874, being engaged at the time on an account of his journey to Sinai, and a second volume of his *Origines Biblicæ*. Beke in 1852 edited, for the Hakluyt Society, De Veer's *Three Voyages towards China*; he also published *The Sources of the Nile* (1860); *British Captives in Abyssinia* (1865); *King Theodore* (1869); *Idol in Horch* (1871); *Jesus the Messiah* (1872). His posthumous work, *Discoveries of Sinai in Arabia* (1878), was issued by his widow.

Bekes, or BEKESVAR, a town of Hungary, at the confluence of the Black and White Körös, 113 miles SE. of Pesth. The inhabitants principally engage in agriculture, and trade in cattle and corn, and honey. Pop. (1890) 25,087. See also CSABA.

Bekker, IMMANUEL, a scholar distinguished by his recensions of the texts of Greek classics, was born at Berlin in 1785, studied in Halle, and in 1811 became professor of Philology in his native city, where he died 7th June 1871. The results of his researches in the libraries of France, Italy, England, and Germany, appear in his numerous recensions of texts derived solely from MSS., and independently of printed editions. The writers included in these recensions are Plato, the Attic orators, Aristotle, Thucydides, Theognis, Aristophanes, as well as Livy and Tacitus.

Bekker, BALTHASAR (1634-98), pastor at Amsterdam, wrote against the belief in Witchcraft (q.v.)

Bektashi. See DERVISI.

Bel and the Dragon, an apocryphal book of the Old Testament, originally appended to the Book of Daniel. It first appears in the Septuagint, and does not seem to have been accepted as inspired by the Jewish Church, nor is there any proof that a Hebrew or Chaldean version of the story ever existed. Jerome considered it a 'fable,' an opinion in which most modern readers will coincide. It was, however, one of the books declared canonical by the Council of Trent (1546). The aim of the writer appears to have been to warn against the sin of idolatry some of his brethren who had embraced Egyptian superstitions. See APOCRYPHA.

Belbeis (ancient *Bubastis Agria*), a town situated on the east arm of the Nile, Lower Egypt, 28 miles NNE. of Cairo. Pop. about 5000.

Belcher, SIR EDWARD, admiral, born in 1799, entered the navy in 1812, and in 1816 took part in the bombardment of Algiers. In 1825 he was appointed assistant-surveyor to the expedition about to explore Behring Strait under Captain Beechey; and from 1836 to 1842 he commanded the *Sulphur*, commissioned to explore the western coast of America. Knighted in 1843, and for five years employed on surveying service in the East Indies, he was in 1852 appointed to the command of the unfortunate expedition sent out by government to search for Sir John Franklin. Belcher published *Narrative of a Voyage round the World in the Sulphur* (1843); *Narrative of a Voyage to the East Indies* (1848); *The Last of the Arctic Voyages* (1855), &c. In 1861 he became rear-

admiral of the Red, in 1866 vice-admiral, in 1867 K.C.B., and rear-admiral in 1872. He died 18th March 1877.

Belchité, a town of Spain, on the Aguas, 22 miles SSE. of Saragossa. Here, on June 18, 1809, the French, under Suchet, completely routed the Spanish under General Blake. Pop. 3262.

Belem'. See LISBON.

Belem', or PARA', capital of the Brazilian province of Para (q.v.).

Belemnites (Gr. *belemnion*, 'a dart' or 'arrow'), an interesting genus of fossil cephalopodous Mollusca, the type of a family called Belemnitidae, to the whole of which the name Belemnites is very generally extended, and which is closely allied to the Sepiade, or Cuttle (q.v.) family. No recent species of Belemnites is known: fossil species are very numerous, and are found in all the jurassic and cretaceous strata, from the lowest lias to the upper chalk, some of which are filled with myriads of their remains. These remains are generally those of the shell alone, which is now known to have been an internal shell, entirely included within the body of the animal, like that of the cuttle. The

Belemnites pistiliformis.

shell, as seen in the most perfect specimens, is double, consisting of a conical chambered portion (the *phragmacone*), inserted into a longer, solid, somewhat conical or tapering, and pointed sheath, which is termed the *rostrum* or *guard*. The space between the phragmacone and sheath is occupied either with radiating fibres or conical layers. The chambers of the shell are connected by a tube (*siphuncle*), so that the animal probably had the power of ascending and descending rapidly in the water. From some well-preserved specimens we learn that its body was furnished with lateral fins, and that it had eight arms and two longer tentacles. The suckers seem to have been provided with horny hooks; and these it probably fixed upon a fish, and descended with its prey to the bottom, like the hooked Calamary (q.v.) of the present seas. Horny mandibles and remains of an ink-bag, like that of the cuttle, have been found in the last and largest chambers of the belemnites; but remains of this chamber, which must have contained all the viscera of the animal, are very rarely preserved, the shell having been very thin at this part. The part most commonly found, and generally known by the name of belemnite, is the solid *guard*, or point into which the sheath was prolonged behind the chambered shell. These have received such popular names as Arrowheads, Petrified Fingers, Spectre-candles, Picks, Thunderstones, &c., from their form, or from the notions entertained of their nature and origin. Belemnites appear to have been of very different sizes; in some of the largest, the mere *muero* is 10 inches long, and the entire animal, with its arms outstretched, must have been several feet in length.

Belfast, the largest and most prosperous commercial and manufacturing city in Ireland, is principally situated in the county of Antrim, of which since 1850 it has been the county town. Belfast has growing suburbs, such as Ballymacarrett and Ballynafeigh on the Down side of the river Lagan, which discharges its waters into Belfast Lough. It is 12 miles from the Irish Sea, 101 N. of Dublin, 130 SW. of Glasgow, and 156 NW. of Liverpool. In this position Belfast stands on an alluvial deposit not more than six

feet above the sea-level. The river Lagan is crossed by the Queen Bridge, which has been recently widened; by the Albert Bridge, which was reconstructed in 1887-88; by a railway bridge; and by a bridge at Ormeau, close to the park of that name purchased from the Marquis of Donegal for popular recreation. Belfast has also several new parks in different parts of the town. On the Antrim side the picturesque hills, rising almost to the dignity of mountains, have an impressive effect, and the general aspect of the town is bright and animated. Though the seat of the linen industry, with a number of mills and manufactures of several kinds, Belfast has a much more pleasant appearance than most British manufacturing towns. On each side of the spacious lough, which resembles in some respects the Lake of Geneva, are a number of pleasant villas, whilst in the higher suburb of Malone, and along the Lisburn Road, handsome edifices of a similar character have sprung up with a cheerful diversity. A fine large new street called Royal Avenue was in 1884 driven through the centre of the town from York Street to Donegal Place. It contains the new post-office, the Ulster Reform Club, the offices of the Water Commissioners, and the free library, which, with many fine shops, form a very imposing thoroughfare. A sight of Belfast at the present time surprises those who have been taught to believe in the poverty and want of enterprise in Ireland. There are 33 Presbyterian churches; 29 Protestant Episcopalian, 15 Methodist, and 6 Roman Catholic. The Queen's College, a handsome brick building, was opened in 1849. The Presbyterian College in 1881 had, in conjunction with the Magee College of Londonderry, the power conferred on it of granting theological degrees. The Catholics and Methodists have colleges of their own, while a Royal Academical Institution and the Belfast Academy, with other institutions of a similar character, supply great educational facilities. The National Schools amount to 130; the Church Educational Society have schools of their own; and there are a number of excellent private schools.

The progress Belfast has made since the middle of the century may be indicated by some of the most recent returns. In the year 1821 the population was 37,117; in 1851 it was just over 100,000; in 1871 it was 174,112; in 1881, 208,122; in 1891, 255,896, of whom about 71 per cent. are Protestants. It thus is as large as were the largest English or Scotch manufacturing towns beyond London, when, in 1848, Macaulay wrote his celebrated third chapter. The area of the borough is 6805 acres; there are 1547 streets; and the number of buildings rose from 18,375 in 1861 to 48,514 at the beginning of 1887. The average number of persons in each house is 5½. The valuation of the borough, which in 1851 was £182,851, in 1886 was £647,114; thus in thirty-five years it had been more than trebled. Since 1867, £65,000 has been spent on the construction of arterial district sewage; and in 1887 a Belfast Main Drainage Act was passed for the purpose of extending, at an expenditure of £300,000, main-trunk and intercepting sewers for collecting all the sewage of the borough, and discharging it into the sea at a great distance from the town. Almost to the close of the parliamentary session of 1887, Belfast was under a very high municipal franchise; but at the time of the passing of the Main Drainage Bill, this franchise was reduced professedly to household suffrage; still, it is practically a £4, 5s. rating franchise. Simultaneously with the improvements in the town, the Harbour Commissioners have been engaged in greatly improving the quays and the harbour. With this object they

had already expended £500,000 when, under an Act of 1883, they obtained power authorising an additional expenditure of about a million of money more. Donegal Quay, devoted to the cross-channel steamboat service, is now a handsome and substantial structure, and there are other quays of similar construction. The returns give a very incomplete estimate of the foreign trade (in 1896, 400 ships of 349,470 tons entered, and 180 of 176,577 cleared), which is for the most part conducted through Glasgow and Liverpool, and is estimated at upwards of twenty millions. The total tonnage of Belfast, which in 1863 was nearly 1,000,000 tons, by 1896 had very nearly doubled itself. The revenue collected in 1886 amounted to £1,658,516, an amount then exceeded only by two ports in the United Kingdom; at present it amounts to £2,500,000 per annum. The valuation has since 1890 surpassed that of Dublin—as does the Belfast population that within the municipality of Dublin. The linen trade, though such a very important one to Belfast, is far from being the sole one. Other industries have since 1855 been developing all round. Among the most remarkable is the shipbuilding trade, of which the firm of Harland and Wolff is the most prominent representative, though other establishments are, according to their means, equally prosperous. Rope manufactures, and the manufacture of aerated waters, as well as several other businesses, including a very large whisky trade, add greatly to the prosperity of the town. At intervals, as in July 1880 and in June 1886, there have been serious riots between the lowest classes of the Protestant and Catholic population, in close proximity to each other. But Belfast is a town of great energy, steadily growing, even under adverse circumstances; handsome and picturesque beyond most large manufacturing towns. In 1888 it received the rank of a city.

See Benn, *History of Belfast to the End of the 18th Century* (1877); Young, *Historical Notices of Old Belfast* (1896); and the present writer's *Ulster as it Is* (1896).

Belfast, a port of entry in Maine, U.S., on the west side of Penobscot Bay, with shipbuilding and some manufactures. Pop. 5294.

Belfort, a town of France, capital of the French remnant of the department of Haut-Rhin, 117 miles ENE. of Dijon by rail. From 1870 this remnant (235 sq. m.), taking its name from the town, has been called the *Territoire de Belfort* (or alternatively *Haut-Rhin*), and consisted of those portions of Haut-Rhin which, seized by the Germans during the war of 1870-71, were restored to France by the preliminaries of peace arranged at Versailles, 26th February 1871. The strategical importance of Belfort was recognised by France on its cession by Austria in 1648, and it was fortified by Vauban. At the outbreak of the Franco-German war, Belfort was a fortress of the first rank; and it maintained, from 3d December 1870 till 16th February 1871, a gallant defence against the Germans. It then capitulated, the defenders marching out with all the honours of war. A memorial of its defence was unveiled in 1884; and the fortifications have been enormously strengthened. Pop. (1872) 8014; (1891) 25,282; of territory, (1891) 83,670.

Belfry (old Fr. *berfrei*; modern, *beffroi*, of Teutonic origin; lit. 'a place of safety'). Originally a kind of movable tower used for defence in sieges, it came to mean a tower to protect watchmen, a watch-tower, beacon-tower, or alarm bell-tower, then any tower where a bell is hung—a bell-tower or turret. The belfry usually forms part of a church, but is sometimes detached from it—as at Evesham, Berkeley, and Beccles, in England, and

still more frequently in Italy (see CAMPANILE). Where a church was built in a deep glen, the belfry was occasionally perched on a neighbouring height, as at St Fève and elsewhere in Cornwall, and at Ardalach and Auldbar in Scotland. At this last place, the bell was hung upon a tree, as was common enough in Scotland at the close of the 17th century. Where the belfry consists of a mere

Belfry at Bruges.

turret, it is often called a *bell-gable* or *bell-cote*, and is placed on the west end of the church; a smaller one being usually placed at the east end for the sanctus bell, for which reason it is placed over the altar. Municipal belfries are more common on the Continent than in this country. When the boroughs began to rise into importance after the 12th century, they asserted their right to have bells to call the burghers together for council or for action. Thus detached belfries arose in the heart of towns, and were regarded as important symbols of their freedom. At a later date, they often became part of the *maison de ville*, or town-house, as at Glasgow and Aberdeen, in this country; at St Quentin and Douai, in France; and at Brussels, in Belgium. The belfry attached to the building known as *Les Halles* (not the town-hall) in Bruges, was commenced in 1291. It is 353 feet high, and possesses a carillon of 48 bells, regarded as the finest in Europe. It is well known through Longfellow's poem.

Belgæ, the name given by Cæsar to the warlike tribes which in his time occupied that one of the great divisions of Gallia bounded on the N. by the Rhine, on the W. by the ocean, on the S. by the Sequana (Seine) and Matrona (Marne), and on the E. by the territory of the Treviri. Their country was level, containing no mountains of any height, except the Vosges in the south. The name seems to have originally designated several powerful tribes inhabiting the basin of the Seine, and to have been afterwards used by Cæsar as a general appellation for all the peoples north of that river. Most probably they were chiefly of Celtic origin, but within their territories were to be found both pure and mixed Germans.

When South Britain was invaded by Cæsar, he found that Belgæ from the opposite shores of Gaul

had preceded him, and were settled in Kent and Sussex, having driven the aborigines into the interior. The Belgæ in Britain resisted for nearly a century the Roman power, but were finally forced to yield to it. Cæsar regarded them as German, but they rather seem to have belonged to the Celtic portion of the Gallic Belgæ. Certainly none of the names of their three towns are Germanic. See Rhys's *Celtic Britain* (1882), and Elton's *Origins of English History* (1882).

Belgard, a town of Prussia, in the province of Pomerania, on the Persante, 16 miles SSW. of Köslin. It has an old castle, and important cattle and horse markets. There are also an iron-foundry, sawmill, &c. Pop. 7117.

Belgaum, or BELGAM, the chief city of a district of the same name in the presidency of Bombay, situated to the E. of the dividing ridge of the West Ghats, at a height of about 2500 feet above the sea, 55 miles NE. of Goa. Belgaum possesses a fort, which in 1818 was taken from the Peishwa by the British, under whom it has increased in wealth and size. The native town lies between the fort on the east and the military cantonment. The site of the town is well wooded, bamboos, mangoes, tamarinds, and banyans being plentiful. It has a superior institution for the education of native youths. The chief articles of commerce are dry fish, salt, dates, cocoa-nuts, coir. Cotton cloth is manufactured here. Belgaum is a seat of the London Missionary Society. Pop. (1891) 40,737. Area of Belgaum district, 4656 sq. m. Agriculture forms the chief occupation of the people, with spinning and weaving, manufactures of pottery, wood, and metals. Pop. (1891) 103,261.

Belgiojos'o, a town of Lombardy, North Italy, in a fruitful plain between the Po and the Olona, 9 miles E. of Pavia. Pop. 4000.—The Princess Cristina of Belgiojoso, an Italian authoress and patriot, was the daughter of the Marchese Trivulzio, and was born at Milan, 28th June 1808. In 1824 she married the Prince of Belgiojoso. She was an enthusiastic labourer in the cause of Italian liberty; raised and supported a body of troops in 1849; travelled in the East; and lived many years at Paris. She died at Milan, 5th June 1871. Amongst her works are *Récits Turco-Asiatiques* (1856); *Asie Mineure* (1858); *Histoire de la Maison de Savoie* (1860).

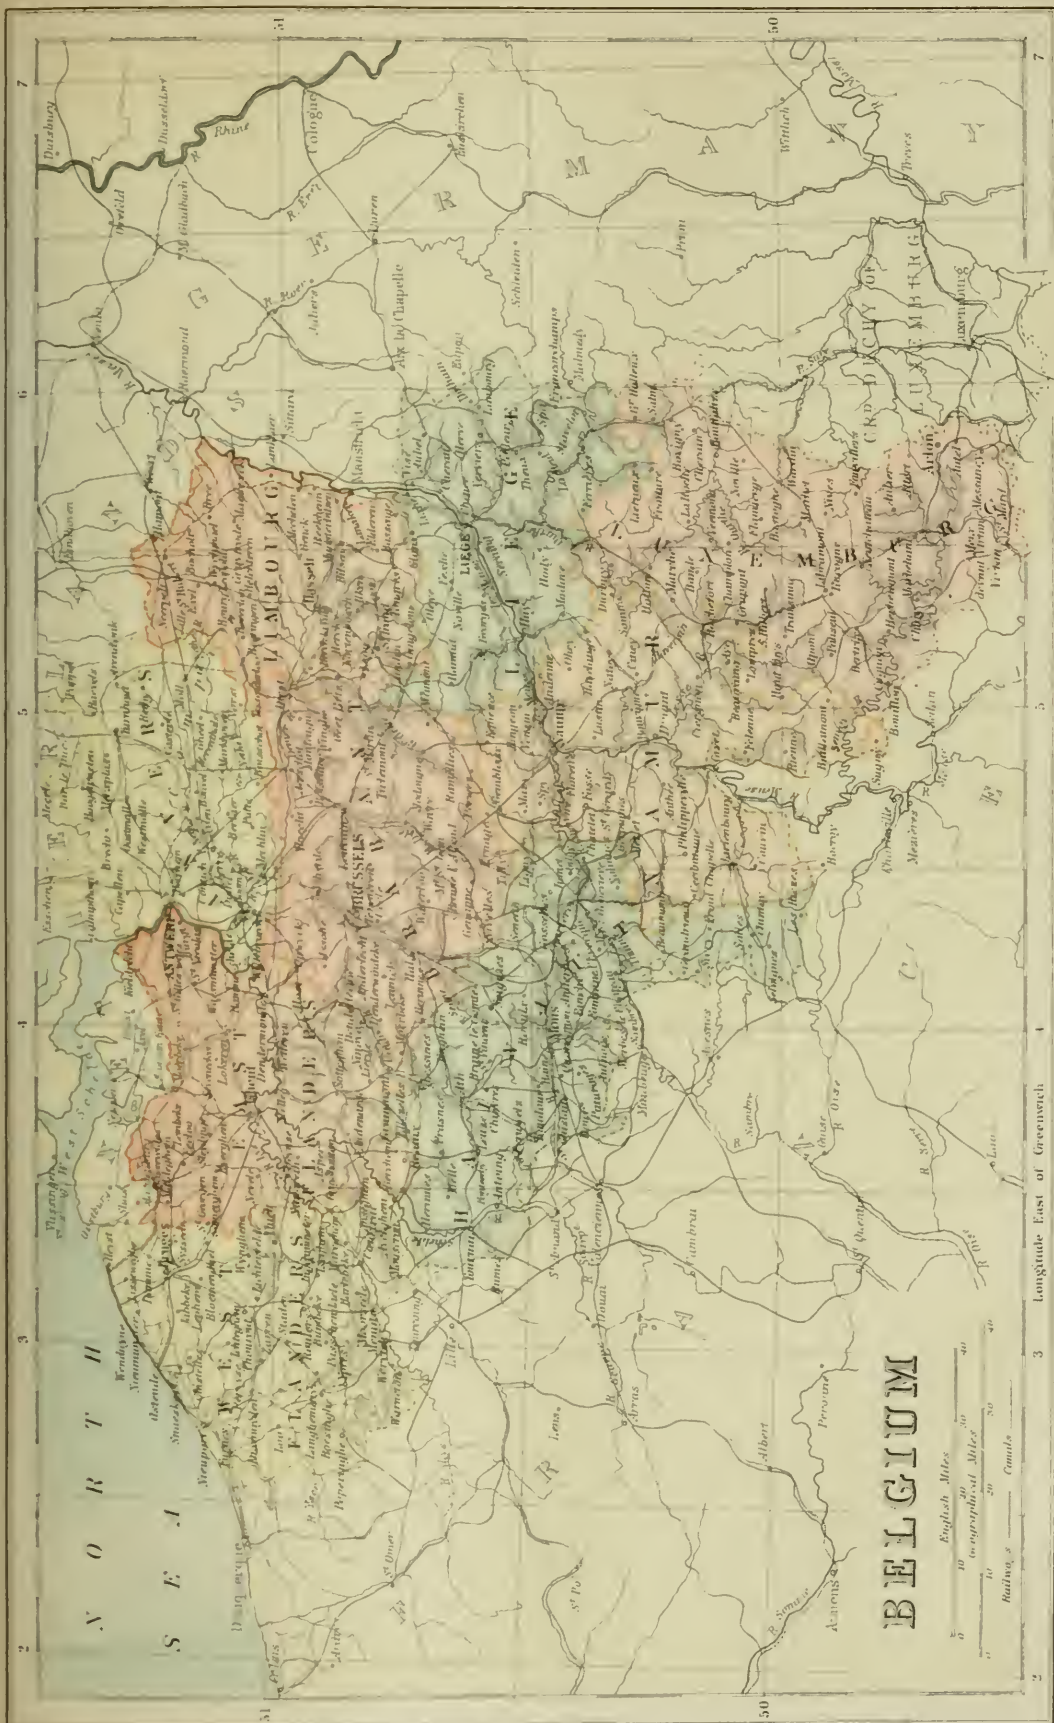

Belgium (Fr. *Belgique*), one of the smaller European states, consists of the southern portion of the former kingdom of the Netherlands (as created by the Congress of Vienna), lying between France and Holland (i.e. the present kingdom of the Netherlands), the North Sea and Rhenish Prussia. Its greatest length from north-west to south-east is 173 miles; and its greatest breadth from north to south, 105 miles.

Area and Population.—The whole area of Belgium is 11,373 sq. m., or slightly over a third of that of Ireland. The population at the census of 1880 was 5,520,009, and at that of 1890, 6,147,041. Beneath are given the provinces, their areas, their population at December 31, 1892, and their chief towns:

Provinces.	Sq. Miles.	Pop.	Chief Cities.
Antwerp.....	1,093	726,233	Antwerp.
West Flanders.....	1,249	749,291	Bruges.
East Flanders.....	1,158	961,007	Ghent.
Hainaut.....	1,437	1,065,881	Mons.
Liège.....	1,117	778,724	Liège.
Brabant.....	1,268	1,136,827	Brussels.
Limburg.....	931	225,000	Hasselt.
Luxemburg.....	1,706	212,171	Arlon.
Namur.....	1,414	330,321	Namur.

Total....11,373 6,195,355

At the same date the kingdom contained seventeen towns with over 20,000 inhabitants. Of these the largest were Brussels, the capital, 488,188

BELGIUM

Longitude East of Greenwich

W & R CHAMBERS, LIMITED LONDON & EDINBURGH.

(including suburbs); Antwerp, 240,343; Liège, 155,898; and Ghent, 151,811.

The population of Belgium is of mixed German and Celtic origin. The Flemings (of Teutonic stock) and Walloons (Celtic in origin), distinguished by their peculiar dialects (see HOLLAND, Vol. V. p. 745; WALLOONS), are still conspicuous among the pure Germans, Dutch, and French. East and West Flanders, Antwerp, and Limburg are almost wholly Flemish; and Brabant mainly so. The line between the Flemish and Walloon districts is sharply defined, the Flemish part being the richest and most cultivated. The French language has gained the ascendancy in educated society and in the offices of government; but the Flemish dialect prevails numerically in the proportion of nine to eight.

Belgium is the most densely peopled country in Europe, the population being 548 to the sq. m., as compared with 497 in England and Wales (in 1891 England without Wales having 540, Lancashire 2080). In Brabant the density was 896 per sq. m. The increase of the Belgian population is due largely to the steady excess of births over deaths, which in the years 1881-85 averaged 57,800 annually. This may be compared with the returns from France during the same period, where, with an area seventeen times greater, and a population more than six times as large, the total average excess was only 93,300. Of the total population in 1890, 45 per cent. spoke Flemish, 41 per cent. French, and 11 per cent. both tongues. In 1880 2,479,750 spoke Flemish only, 2,237,870 French only (including Walloon), 41,000 German only, 420,300 Flemish and French, 35,350 French and German, 2800 Flemish and German, and 13,400 spoke all three languages. There were, besides, 6500 foreigners.

Physical Aspect.—Belgium is, on the whole, a level, and even low-lying country; diversified, however, by hilly districts. In the south-east, a western branch of the Ardennes highlands makes its appearance, separating the basin of the Maas from that of the Moselle, but attains only the moderate elevation of 2000 feet. In the northern portions of Antwerp and Limburg, a naturally infertile district named the Campine, composed of marshes and barren heaths, extends along the Dutch frontier. In Flanders the land becomes so low that, in parts where the natural protection afforded by the dunes is deficient, dikes have been raised to check the encroachments of the sea; and the once impassable morasses of the *Morini* and the *Menapii*, which stayed the progress of Caesar's legions, are now drained and converted into fertile fields surrounded by dense plantations. Colonies having been settled on whatever patches of the sandy, marshy Campine district it was deemed possible to reclaim, it has been largely cleared and drained, and become the centre of a thriving agricultural industry. At the same time, the coast is said to be undergoing a change by which the land southward is gradually gaining on the sea, while the northern coast is losing.

Hydrography, Climate, Agriculture, &c.—The abundant water-system of Belgium is chiefly supplied by the great navigable rivers Scheldt and Maas, both of which rise in France, and have their embouchures in Holland. The Scheldt, like the Maas, is navigable all through Belgium. Its tributaries are the Lys, Dender, Durme, and Ruppel. The Maas, or Meuse, receives in its course the waters of the Sambre, the Ourthe, and the Roer. These natural hydrographical advantages are increased by a system of canals (44 in number, with an entire length of 563 miles). The climate is, in the plains near the sea, cool, humid, and somewhat unhealthy; but in the higher

south-east districts, hot summers alternate with very cold winters. The mean annual temperature at Brussels is 50° F. The rainfall ranges from 27.5 inches in the west, to 40 inches in the district east of the Maas. The Ardennes districts yield a large supply of wood, and their forests abound in game and other wild animals; while the level provinces raise all kinds of grain—wheat, rye, oats, and barley, leguminous plants, hemp, flax, colza, tobacco, hops, dye-plants, and chicory. The beet is cultivated in increasing quantities, both for sugar and for fodder. Belgium contains nearly 7,278,000 acres, of which almost two-thirds are in ordinary cultivation, more than one-eighth is meadow and pasture, one-sixth is under wood, and less than 600,000 acres are waste or water. Some hundreds of acres are devoted to vineyards, but the wine produced is of an inferior quality. Good pasturage is found on the slopes and in the valleys of the hilly districts, and in the rich meadows of the low provinces. Gardening occupies not less than 130,000 acres; indeed, it has been said that the agriculture of Belgium is gardening on a large scale, so carefully and laboriously is every inch of soil cultivated by the farmers, the vast majority of whom are small holders owning less than one hectare (about 2½ acres) of land. The spade is still the principal instrument used. The interests of this class are promoted and superintended by provincial committees of practical men, who are directed by a central council, and improvements are encouraged and rewarded at quinquennial exhibitions at Brussels. The state supports four agricultural schools and nine experimental stations, including a school of forestry, to which pupils are admitted for a fixed period as boarders; and at 29 middle-class state schools courses of agricultural lectures are delivered to the farmers of the district. Belgium is famous for its horses, and to improve the breeds a government stud of stallions is maintained at Tervueren. In the Campine, the care of bees and the cultivation of the silkworm are encouraged, and its butter is considered the best in Belgium. There are valuable fisheries on the coast, but foreign fish being admitted free of duty, the fishermen of Holland, England, and France have proved keen competitors in the Belgian markets. This led in 1887 to repeated disputes and much bad feeling, culminating in a series of riots at Ostend.

Geology.—The geological formations of Belgium are closely associated with those of France and Britain. The greater portion of the country is covered with *Tertiary deposits*. A line drawn across the course of the Scheldt, by Mechlin, along the Demer and Maas, will have on its northern and north-western aspect a tract of Tertiary deposits, bounded northwards by the sea. In these Tertiary strata the different geological periods are fully represented; but only the second, containing the Pliocene deposits, is rich in fossils. The *Secondary deposits* occupy an extensive tract in the centre of Belgium, between the Scheldt and the Demer. The most important district, economically, is the south-western, consisting of *Palaeozoic rocks*—Silurian, Devonian, and Carboniferous.

Mineral Products.—Belgium is rich in minerals, which, next to its abundant agriculture, constitute the chief source of its national prosperity. The four provinces in which they are found are Hainault, Namur, Liège, and Luxembourg. These yield lead, copper, zinc, calamine, alum, peat, marble, limestone, granite, slate, iron, and coal. Lead and zinc are wrought to some extent in Liège; copper in Hainault and Liège; manganese in Liège and Namur; black marble at Dinant; slates at Herbeumont; and calamine principally at Liège.

But these products are insignificant compared to the superabundance of coal—from anthracite to the richest gas coal—and iron, in which Belgium ranks next to England. The mines are superintended, under the minister of the interior, by a corps of mining engineers, one of whom is appointed over each of the six mining districts.

There are in Belgium some 250 coal-mines, employing 120,000 persons, and producing about 20,000,000 tons, of a total value of £5,000,000 or £6,000,000. The metallic mines produce about 200,000 tons of iron ore, 2500 of pyrites, 18,000 of calamine (zinc), 2000 of blende (also a zinc ore), 3000 of sulphuret of lead, and 450 of manganese. These mines give employment to over 1500 workmen; but this industry has fallen off, the corresponding number of miners in 1865 having been 11,800. There are upwards of 500 ironworks, producing manufactured iron and steel to the value of £6,000,000 or £7,000,000, and the produce of the quarries is valued at near £2,000,000.

Manufactures.—The chief manufactures are linen, woollens, cotton, silk, lace, leather, and metals. Flax is one of the most valuable products of Belgium. The great seats of the linen manufacture, the oldest in Belgium, are in Flanders; it employs some 350,000 persons. The lace industry has fallen off in importance, but still employs 150,000 workers and a capital of two millions sterling. Centres of the woollen manufacture are Ypres, Ghent, Tournay, and especially Verviers, which alone employs 20,000 workmen in this branch of industry. Brussels and Louvain have large carpet manufactures, and Hainault supplies a considerable amount of hosiery. The principal seat of the cotton trade is Ghent, where the industry was first established in 1798. It employs over 30,000 persons. Belgian leather has a good reputation, and the manufacture of gloves has made great progress in recent years. Metallurgy also has rapidly increased in productiveness since 1816, when Cockerill (see *SERAING*) introduced into Belgium the English method of smelting iron with coke. The principal seats of the metal manufacture are Liège, Ghent, Charleroi, Mons, and their neighbourhoods. There are large ordnance foundries at Liège and Antwerp, and celebrated makers of firearms and machinery in Liège; nail-making at Charleroi; manufactures of copper at Malines, and of tinware at Liège; wire and brass factories at Namur, Liège, and Brussels; zinc manufactures at Liège; and lead and shot factories at Ghent. Gold and silver goods are manufactured at Brussels, Liège, and Antwerp. Besides these, we may mention the straw-bonnet manufacture in the neighbourhood of Liège; the calico-printing at Ghent and Brussels; the paper fabrics of Brussels and Liège; the glass-works of Charleroi, Liège, and Namur, whose annual output reaches a value not far below £2,000,000; the porcelain of Tournay; and the sugar-refineries, of which there are 130. There are in Belgium upwards of 2500 breweries, mostly small, and 250 distilleries.

Commerce.—In the middle of the 13th century, Flanders, with Bruges as its chief seat of manufactures, had surpassed all its neighbours in industry. After the discovery of America, Antwerp took the place of Bruges. But the unhappy period of Spanish oppression and the war in the Netherlands deeply depressed Flemish commerce. Separation from Holland has also been indirectly favourable to the development of Belgian resources; and its admirable network of railways (2850 miles open in 1894) has greatly promoted commerce. There are 1000 miles of navigable rivers and canals.

The unit of the Belgian monetary system is the franc, and in 1865 Belgium, along with France, Italy,

Switzerland, and Greece, entered on a monetary league, in which these states agreed to adopt the French decimal system of coins, weights, and measures, and established a reciprocity of currency, whereby their respective unit coins would have the same value throughout their territories.

Among the principal articles of export are coal, flax, linen, woollen and cotton goods, glass, firearms, and nails. About a fourth of the whole is consigned to France, and most of the remainder to Germany, England, and Holland. The carrying trade is almost entirely in the hands of the British, the native shipping being only some 60 vessels, of under 100,000 tons burden, besides 350 fishing-vessels. In 1882-92 the exports had an annual value of from £47,000,000 to £61,000,000; the imports from £53,000,000 to £72,000,000. The commercial intercourse with Great Britain is represented by exports thither to the amount of from £15,000,000 to £17,000,000 a year (woollen yarn, silks, flax, sugar, iron manufactures, eggs, poultry and game, &c.), and by imports from Britain worth from £6,300,000 to £7,600,000 (cottons, cotton-yarns, woollens, machinery, iron, &c.). Imports and exports in 1831 were £3,750,000 and £4,025,000 respectively.

Religion.—The Roman Catholic is the dominant religion. Although full liberty of worship is guaranteed to all, and the ministers of each denomination are paid by the state, almost the entire population are Roman Catholics, the number of Protestants being set down at 15,000, of Jews at 3000. The supreme Catholic dignitaries of Belgium are the Archbishop of Mechlin, and the five diocesan bishops of Bruges, Ghent, Tournay, Namur, and Liège. There are over 1200 conventual houses, inhabited by 4000 monks and 21,000 nuns.

Culture.—Diversity of dialects has retarded the growth of the national intellect and the formation of an independent national literature to act as the bond of national unity. The Flemish element—the most important—has done much of late to foster the Flemish tongue, and if possible secure its predominance. Flemish theatres are supported in the great towns; a Royal Academy to encourage the study of its language and literature was opened at Ghent in 1886; and in 1887 the king was constrained to make speeches in Flemish. Scientific and literary societies, museums, and public libraries, are of course numerous. Great efforts are being made to improve the musical standard of the people; there are as many as 60 musical schools throughout the country, with about 1000 pupils, and the conservatoires of Brussels, Ghent, and Liège count 3000 or 4000 pupils. Painting and architecture formerly flourished in the wealthy old towns of Flanders; and although, after the brilliant epoch of Rubens and his pupils, a long period of dullness followed, in modern times a revival of art has taken place, and important academies have been founded at Antwerp and Brussels. For the achievements of the old Flemish school, see *PAINTING*, and the articles on *RUBENS*, *TENIERS*, *VAN DYCK*.

The Belgian school-system has undergone many changes during the present century. In 1879 education in the public schools was completely secularised; but on the succession of a Catholic ministry in 1884, the government support was withdrawn from these schools, and each parish had to decide whether its primary school should be continued at the parish's cost, or the children be sent to the church school. As a result, numerous church schools have been recognised as public schools, the others having been abolished. There are universities at Ghent and Liège, a Catholic university at Louvain, a free university at Brussels, 10 *Athénées*, over 150 middle-class and many private schools, and four Jesuit gymnasia. Yet in

1890, 27 per cent. of the inhabitants over fifteen years of age could neither read nor write.

Literature.—The older literature of the country falls to be discussed under HOLLAND (*Language and Literature*). Of modern authors in Flemish, Conscience (q.v.) the novelist and Willems the philologist are noteworthy; the work *Onze Dichters*, published in 1880, is an anthology of the poets who, since 1830, have contributed to the revival of Flemish literature. Of late, however, the main current of Belgian literary activity runs mainly in the channels of politics and modern national history, and in the French tongue. Historians are Pouillet, Moke, Namèche, and Juste; Laveleye was a well-known publicist. Quetelet, the statistician and astronomer, was a Belgian. The *Bibliotheca Belgica* is a work on a large scale containing many of the chief documents of national history. The *Bibliographie Nationale* (1880) is a dictionary of Belgian writers and their works from 1830 to 1880; there is also a *Bibliographie de l'Histoire de la Belgique*.

Army.—The organisation of the Belgian army is established by a law of 1873, under which the peace-strength is fixed at 47,000 men, to be raised in time of war to 103,000. It is intended solely for defence, and to preserve the neutrality of the territory; it is formed by conscription, to which every healthy man who has passed his nineteenth year is liable. Substitution is allowed. The legal period of service is eight years, but five of these are, as a rule, passed on furlough or in the reserve. Besides the standing army, there is a *Garde Civique*, numbering in all some 45,000 men, with a reserve of 90,000. The importance of Belgium in a military point of view, and the length of its frontier towards Holland, Germany, and France, affords a reason for the maintenance of fortifications at Antwerp, Breda, Namur, Diest, Liège, Mons, Tournai, and Ypres. The chief arsenal is at Antwerp.

Finances.—In the period 1885-1891 the revenue rose from £13,300,000 to over £16,000,000, but there was an annual deficit (amounting in 1890 to £1,600,000, in 1896 to only £35,000). The debt, with a gross total of close on £90,000,000, has been incurred mainly for works of public utility, especially state railways; and its interest is more than covered by the revenue from the railways. The debt includes a proportion of the debt of the kingdom of the Netherlands.

Government.—The government of Belgium is a limited constitutional and hereditary monarchy, and was established in its present form by the revolution of 1830. The administration of justice is governed by the *Code Napoléon*. The legislative body consists of two chambers—the Senate, and the Chamber of Representatives. The members of the Chamber are paid £160 a year, and have a railway pass to and from their homes. By the constitution as amended in 1893 all citizens (not disqualified) of twenty-five years of age and upwards have a vote; and citizens over thirty-five, married or widower, with legitimate issue, and paying 5 francs a year in house-tax, have a supplementary vote—as has also every one of the younger class possessed of a certain amount of property. Deputies are elected for five years. The senators are elected for eight years, partly directly, by a similar constituency, and partly indirectly. The directly elected members are half as many as those in the Chamber of Representatives. The others are chosen by the provincial councils, from 2 to 4 for the province according to population. A senator must be 40 years old, and pay 1200 francs of direct taxes.

History.—The history of Belgium dates from 1831, when the Southern Netherlands parted from Holland and became an independent kingdom. The narrative prior to 1831 of the provinces forming

the present Belgium will be found in the article HOLLAND. But it may be well to introduce our account of Belgian history with a brief sketch of its previous development. On the downfall of the Roman empire, the *Gallia Belgica* of the Romans passed under the dominion of the Franks. As the feudal system arose, the country was distributed under a number of dukes and counts with a considerable measure of local independence. These provinces were absorbed by the great House of Burgundy from 1385 onwards, and they continued under that rule till the downfall of Charles the Bold in 1477. With his daughter Mary they then passed to the House of Hapsburg, and remained with the Spanish branch of that line till the peace of Utrecht in 1713, being known as the Spanish Netherlands to distinguish them from the northern provinces, which, in the reign of Philip II., had revolted from Spain, and formed a Protestant Republic, while the southern provinces continued subject to the Roman Catholic Church. In 1713, by the peace of Utrecht, the Spanish provinces were transferred from Spain to Austria, as the Austrian Netherlands. The country was conquered by Pichegrin in the campaign of 1794, and subsequently united to France by the treaties of Campo-Formio and Lunéville. It now shared the fortunes of France during the Consulate and the Empire, received the *Code Napoléon*, and in all political relations was organised as a part of France. After the fall of Napoleon it was united with Holland under Prince William-Frederick of Nassau, and its boundaries were defined by the Congress of Vienna (May 31, 1815). In the campaign of 1815 Belgium was once again, as it had often been, the 'battle-field of Europe'; and Belgian troops were present at Waterloo.

The union of what had been the Spanish or Austrian Netherlands to Holland in 1815 was from the first an arbitrary one, as the people of the northern and southern parts of the united kingdom differed essentially in religion, language, interests, and historic feeling. Nor was the policy of the Dutch fair or conciliatory. The Dutch almost exclusively occupied the higher posts in the army and administration. The use of French in the southern provinces was discouraged, and the privileges of the Catholic clergy were curtailed. Old feelings of patriotism and the interests of self-government were equally disregarded. Thus, Liberals and Catholics were alike ready to revolt against Dutch supremacy, and the concessions tardily made to satisfy the growing discontent did no good. The outbreak of the French Revolution in 1830 set the example to the discontent across the frontier. On the king's birthday (August 24, 1830), several riots occurred in various towns of Belgium. At this period, however, the idea of separation from Holland does not seem to have presented itself consciously to the Belgian mind; the deputies who were sent to the Hague to state the causes of the general dissatisfaction merely insisted on Belgium's possessing a separate administration, with the redress of particular grievances. But the dilatory and obstructive conduct of the Dutch deputies in the States-general assembled at the Hague on the 13th September, together with the ill-advised occupation of Brussels by an army of 14,000 men, exasperated the Belgian nation beyond measure. A new and more resolute insurrection instantly took place. In seven days the people had deposed the old authorities and appointed a provisional government. Prince Frederick, the son of the Dutch king, who commanded the troops, was compelled to retreat from Brussels to Antwerp, having suffered considerable loss. On the 4th of October Belgium was declared independent by the provisional government. The useless bombard-

ment of Antwerp by the Dutch general Chassé (October 27) increased the bitterness of feeling, and rendered reconciliation wholly impossible. At the national congress of November 10, out of 200 votes only 13 were in favour of republican government. Meanwhile, the London Congress had assembled, and after mature deliberation, the representatives of Austria, Prussia, Russia, and England recognised the severance of the two kingdoms as a *fait accompli* (December 20). When the Belgian Congress met, it appointed Baron Surllet de Chokier provisional regent, but on June 4, 1831, it elected Prince Leopold of Saxe-Coburg king of the Belgians. Leopold entered Brussels on the 21st July, and subscribed the constitution. His marriage to a daughter of Louis-Philippe secured French support. Holland refused to acknowledge the validity of the decision of the London Congress, and declared war, which was speedily terminated by France and England—Holland securing that Belgium should annually pay 8,400,000 florins as interest for its share in the national debt of the Netherlands. And it was agreed by the powers that Belgium should remain an independent and perfectly neutral state. Holland, however, was still dissatisfied, and ventured to employ force. England and France were compelled to interfere. The French besieged and took Antwerp, still held by the Dutch troops; and the blockade of the coast of Holland having brought the Dutch to terms, the dispute was closed by a treaty signed in London, May 21, 1833.

In 1838 it seemed as if Holland and Belgium were likely to engage in war once more. According to the 'twenty-four articles' of the 'Definitive Treaty,' Belgium was under obligation to give up Limburg and a part of Luxembourg during the above-mentioned year. This it now refused to do, and put its army on a war-footing; but its obstinacy finally gave way to the unanimous decision of the five great powers, and on the 19th April 1839 a treaty of peace was signed at London, Belgium's annual share of the Netherlands' debt being at the same time reduced to 5,000,000 florins; and both Limburg and Luxembourg being partitioned between Holland and Belgium.

After 1840 the opposition of the Catholic to the Liberal party became more and more decided, the educational laws not being satisfactory to the clergy, until, in July 1845, the liberal Van de Weyer endeavoured to confirm the so-called 'union' of the two parties. In 1846 a purely Catholic ministry took office; but in 1847 a liberal ministry was formed by Rogier. The revolutionary tempest of 1848 menaced the tranquillity of the country; but the king disarmed hostility by promptly declaring himself ready to retain or to surrender the crown of Belgium, according to the decision of the people.

In July 1848 the elections greatly strengthened the liberal-constitutional party, and in 1850 the educational question was supposed to be settled on soundly liberal principles; but since then there has been a keen and continued struggle between Progressists and Ultramontanes, the balance of power shifting from time to time. Thus liberal ministries have been in power from 1857 to 1864, and in 1878 (under Frère-Orban); clerical ministries in 1870, 1876, 1880, and 1884, the education question being the chief bone of contention. On the death of Leopold I. in 1865, his son had succeeded as Leopold II. In 1861 Belgium took part in the London conference for settling the Luxembourg question, which threatened to plunge Europe in war, but did not sign the guarantee for the neutrality of Luxembourg. On the outbreak of the Franco-German war in 1870, the Belgians, fearing risks both from Prussia and from France, mobilised their army; but in a special treaty

arranged by England, both belligerents recognised anew the neutrality of Belgium, guaranteed in 1831 and 1839. In 1885 the Congo Free State (q.v.), under the presidency of Leopold II., was acknowledged by the powers. Although the country has on the whole steadily grown in prosperity, and constitutional principles have been generally strengthened, yet 1886-87 witnessed industrial riots and Socialist disturbances of a serious aspect, attended at Liège, Mons, Charleroi, and other places, with great violence. The king at the opening of the chambers in November promised that measures of reform should be introduced, and this had the effect of quelling the disturbances. In 1880 the jubilee of the state was celebrated with much enthusiasm.

Compare FLANDERS and the articles on the several provinces; see also Genonceaux, *La Belgique* (1879); Hymans, *La Belgique Contemporaine* (1880); Wauters, *La Belgique, Ancienne et Moderne* (1882 ff.); the *Annuaire Statistique*; and the histories by Juste (4th ed. 1868), Moke (7th ed. 1881), and Hymans (5 vols. 1880).

Belgorod' (Russian *Bjelgorod*, 'white town'), a town in the Russian government of Kursk, on the Donetz, 412 miles S. of Moscow by rail. It is an archbishop's see, has numerous churches, two monasteries, manufactures of leather, soap, and woollens, and carries on a considerable trade in wax, bristles, and hemp. Three important fairs are held here during the year. Pop. 16,097.

Belgrade (Serb *Bielgorod*, 'white town'), an important fortified and commercial city, the capital of the kingdom of Servia, lies opposite Semlin, at the confluence of the Save and Danube, 215 miles SSE. of Pesth, and 234 miles NNW. of Vranja, by rail. The walls have disappeared since 1862; the last and finest of the five gates was demolished in 1868; and the citadel is hardly up to the requirements of modern warfare. Year by year the town is losing its old Turkish aspect, becoming more modern, more European. Only one mosque is left for the tiny remnant of Mohammedans, whilst there are seven churches and two synagogues. The royal palace, the residence of the metropolitan, the national theatre (1871), and the public offices, are the principal buildings. Opposite the theatre is a bronze monument (1882) to the murdered Prince Michael III. Belgrade has but trifling manufactures of arms, cutlery, saddlery, silk goods, carpets, &c. It is, however, the entrepôt of the trade between Turkey and Austria. Pop. (1872) 26,674; (1890) 54,249. Belgrade is the *Singidunum* of Ptolemy. Its position has made it the chief point of communication between Constantinople and Vienna, and the key to Hungary on the south-east. It has consequently been the scene of many hard-fought contests. The Greeks held it until 1073, when it was captured by the Hungarian king, Salomon. After this, it passed through the hands of Greeks, Bulgarians, Bosnians, and Servians, and these last proprietors sold it in 1426 to the Emperor Sigismund. In 1440 it was unsuccessfully besieged by the Turks, with a large and vain outlay of time and money; and when stormed (1456), was retaken from the Turks by the heroism of Hunyadi and Capistrano. In 1522 it was carried by the Sultan Soliman II. In 1688 it was stormed and taken by Maximilian, Elector of Bavaria; but in 1690 was recaptured by the Turks, when the Christian garrison had been reduced to 500 men. In 1692 Belgrade was vainly besieged by the Duke of Croy; and in 1717 the citadel surrendered to Prince Eugene, after he had defeated an army of 200,000 Turks, with a loss to them of 20,000 men. But in 1739 Belgrade again changed owners, the Turks obtaining it without a shot. In conformity

with the treaty then signed, the fortifications were demolished. In 1789 it was again taken by the Austrians under General Laudon; but by the treaty of peace (1791), was restored to the Turks. From 1806 to 1812 it was in the possession of the insurgent Servians; and in 1862, after a wanton bombardment from the citadel, it was made the capital of the principality of Servia, though the citadel remained in the hands of the Turks till 1867.

Belgravia, a district in the southern part of the West End of London, bordering on Hyde Park and Buckingham Palace Gardens. The word, now proverbial for birth, wealth, luxury, and fashion, is derived from Belgrave Square, in the centre of that quarter; and has its name from one of the titles of the Duke of Westminster, who owns the whole district. Belgrave is a parish in Leicester-shire.

Bel'ial, or, more accurately, *Bel'ial*, a Hebrew word, often treated by the translators of the authorised version as a proper name, but really an abstract term meaning 'that which is without use or profit,' 'worthlessness,' hence 'wickedness.' It is mostly used in the forms 'son of Belial,' 'man of Belial'; but the adjunct is often omitted, and the word stands by itself as a term of reproach.

Belief is a term which is sufficiently definite for most ordinary purposes; but it is used with some variety in meaning, and psychologists do not always agree in the tests they give for distinguishing belief from other states of mind. The word is used to mean the acceptance of a proposition, statement, or fact as true on the ground of evidence, authority, or irresistible mental predisposition; the state of trust in and reliance on a person, thing, or principle; as also for the fact believed, and sometimes specifically for the apostles' creed. Belief is by some distinguished from knowledge, inasmuch as the latter rests on evidence, while belief rests on authority. Belief should, some say, not be used of facts such as are occurring in one's own experience, or principles of which the opposite implies absurdity, such as the axioms of geometry. These we *know*; and according to this view, the term should be limited to cases where a proposition is accepted without evidence, or where such evidence as is available implies only probability. On the other hand, the psychologists of what is called the intuitive school are accustomed to regard as beliefs the fundamental data on which reasoning rests; and to say that all knowledge rests ultimately on belief. Belief, they say, may admit of all degrees of confidence, from a slight suspicion to full assurance. There are many operations of mind in which it is an ingredient—consciousness, remembrance, perception. Kant defined *opinion* as a judgment which is insufficiently based, subjectively as well as objectively; *belief*, as subjectively sufficient but objectively inadequate; *knowledge*, as both subjectively and objectively sufficient. The strongest beliefs may of course be false; beliefs in ghosts, astrological prognostications, &c., are usually treated as superstitions. Beliefs as such rest on grounds regarded as sufficient by the person believing, who is prepared to act on his belief; but their grounds may have absolutely no validity for any other person. Such beliefs are nevertheless very real. On the other hand there are many propositions accepted traditionally, and spoken of as beliefs, which are not real vital abiding truths for those who nominally accept them: which have no influence on character or mental tone, and on which those who hold them would not be prepared to act. Faith is a word used in very much the same sense as belief, but specially signifies the acceptance of and reliance on the truths of religion.

For this use, see FAITH, GOD, IMMORTALITY, JUSTIFICATION.

Belisarius (Slav. *Beli-tzar*, 'white prince'). This heroic and loyal soldier, to whom the Emperor Justinian was principally indebted for the glory of his reign, was born at Germania, in Illyria, about 505 A.D. Appointed to the command of the eastern army of the empire, stationed on the confines of Persia, he gained in 530 a victory over a Persian army nearly twice as large as his own. In the following year, when the Persians had penetrated into Syria, Belisarius was compelled by the impatience of his troops to offer battle at Callinicum on the Euphrates, and his defeat was followed by his recall. He still remained, however, the firm supporter of his sovereign. In Constantinople, the strife of the two parties, styled the 'Green' and the 'Blue,' had endangered the authority and even the life of Justinian; already a new emperor, Hypatius, had been elected, when Belisarius attacked and slew in the hippodrome 30,000 of the Green or anti-loyalist party, and thus restored tranquillity. Prior to this he had married a wealthy but profligate lady, Antonina, whom he loved with blind uxoriousness.

The military career of Belisarius may be divided into two great epochs—the war against the Vandals in Africa, and the war against the Goths in Italy. The first of these epochs was commenced by Justinian sending Belisarius in 533 with an army of 15,000 men into Africa, in order to recover the provinces there held by the Vandal king, Gelimer. After achieving two victories, Belisarius made the king a prisoner, seized his treasures, and conquering Sardinia, Corsica, and the Balearic Isles, brought him to Constantinople, where he appeared in a triumphal procession of the conqueror—the first that a subject had enjoyed since the days of Tiberius. The African Vandals never recovered from this overthrow. Medals were struck in Belisarius's honour; and on the 1st January 535 he was invested with the dignity of 'consul.' The second war was occasioned by Justinian's attempt to wrest Italy from the hands of the barbarians. In 535 Belisarius conquered Sicily; and in the autumn of 536 he occupied Lower Italy. He entered Rome by amicable arrangement with the inhabitants; and finding his forces not strong enough to contend with the Goths in open field, he allowed himself to be besieged for a year, when the siege was raised by the Goths. In 538 Narses had been sent with a reinforcement for the army in Italy; but some misunderstanding occurring between the two generals, they were prevented from relieving Milan, which in 539 was carried and devastated by Braias, nephew of the Gothic king, Vitiges. Consequently, Narses was recalled from Italy; and Belisarius, now placed at the head of both armies, refused to assent to a treaty proposed by Justinian's ambassadors to Vitiges, who had persuaded the Persian king, Chosroes, to invade the eastern Roman territory. Belisarius drove the Goths back to Ravenna, which he captured in 540, along with Vitiges himself. But before he could complete his conquest of the Goths, he was recalled by Justinian to Constantinople. In 541–542 he was engaged in a campaign against the Persians, who had captured Antioch; but was again recalled on account of slanderous representations. His second great struggle with the Ostrogoths now begins. In 544 the barbarians under Totila again invaded and reconquered Italy. Belisarius was sent against them, but with an insufficient army. He, however, maintained his ground for five years, and even succeeded so far as to regain possession of Rome. But in spite of his repeated entreaties, no reinforcements were sent

to him; and in 548 he gave up the command, his rival, Narses, being appointed in his place. In 559, after ten years of retirement, Belisarius once more came forward at the head of an army hastily collected, and overthrew the Bulgarians who were threatening Constantinople. Here this faithful servant, who at Ravenna had refused the crown of Italy offered to him by the Goths, was at length accused of a conspiracy against Justinian, and imprisoned (563); but Justinian, becoming convinced of Belisarius's innocence, restored him after six months to all his honours. He died in 565. Tzetzes, in the 12th century, was the first to aver that, during his half-year's imprisonment, Belisarius suspended a bag from the window of his cell, and exclaimed to those who passed by: 'Give an obolus to Belisarius, who rose by merit, and was cast down by envy!' Lord Mahon, in his *Life of Belisarius* (Lond. 1829), endeavours, but without success, to confirm the tradition of Belisarius being deprived of sight and reduced to mendicancy—a fiction given in Marmontel's romance, which supplied the painter Gérard with the subject for a fine picture.

Belize, or **BRITISH HONDURAS**, a British colony washed on the E. by the Bay of Honduras, in the Caribbean Sea, and elsewhere surrounded by Guatemala and Mexico. It forms the south-east part of the peninsula of Yucatan, and measuring 180 by 60 miles, has an area of 7562 sq. m., or a little larger than Wales. In 1891 the population was 31,471, of whom about 1600 were whites. The river Belize traverses the middle of the country, and the Rio Hondo and the Sarstoon form respectively its north-western and its southern boundary. The Cockscomb Mountains (4000 feet) are the highest eminences, the land all along the coast being low and swampy. The country has a general tropical fertility; its chief exports are mahogany and logwood, besides sugar, coffee, cotton, sarsaparilla, bananas, plantains, and india-rubber. The yearly value of the imports ranges between £160,000 and £269,000; of the exports, between £124,500 and £317,500. The name Belize is probably a Spanish corruption of the name Wallis, one of the early British settlers; otherwise it is usually referred to the Fr. *balise*, 'a beacon.' Those early settlers, buccaneers at starting, then logwood-cutters, were frequently attacked by the Spaniards; but since 1798, when they repulsed a fleet and a land-force of 2000 men, their occupation has been formally acquiesced in. Since 1862 Belize has ranked as a British colony, with a lieutenant-governor, whose rank was raised in 1884 to that of governor. Belize, the capital, is a dépôt for British goods for Central America, and has a pop. of about 6600. See A. R. Gibbs's *British Honduras* (Lond. 1883).

Bell. Though there has been some variation from time to time in the substance of which bells are formed, yet in all ages the best-approved has been a mixture of copper and tin called bronze. The proportions of the metals are by no means the same in all cases. The small bells found by Mr Layard in the palace of Nimroud contain 10 parts of copper to 1 of tin; but such an excess of the former metal is rare, and 2 to 1 was for ages in Europe a more approximate ratio. For instance, in the reign of Henry III., 1050 lb. of copper and 500 lb. of tin were allowed, together with old bell-metal, for casting three bells for Dover Castle. The tendency of after-ages has been to increase the proportion of copper, which is stated on good authority to be in the ratio of 13 to 4 to the tin. Of late, steel bells have been cast in Sheffield by Riepe's patent, but these have a less sustained vibration, which is also the result of attempting to

extract from a specified amount of bronze a deeper note than it is fairly capable of affording. The fragility of glass bells will prove a serious obstacle to their use, whatever beauty there may be in their sound. As to hand-bells, crotals, and the like, they have been made of almost endless variety of material. Silver, however, is always injurious to the tone of any bell, great or small, and it is only the eye which feels pleasure from these little instruments. An elegant specimen of a silver-gilt hand-bell, which belonged to Mary, Queen of Scots, was exhibited in the year 1887 at Peterborough among a number of other objects connected with that unhappy queen. The pitch of a bell is regulated by the thickness of the

Queen Mary's Hand-bell.

striking-place in proportion to the diameter, the ratio being about 1 to 12 in a bell of 10 cwt. Some medieval bells of good tone are remarkable for the thinness of the sound-bow.

From a remote antiquity cymbals and hand-bells were used in religious ceremonies. In Egypt we find that the festivals of Isis were celebrated with the sound of *sistra*, apparently small crotals. Aaron and other Jewish high-priests wore golden bells attached to their vestments; and the priests of Cybele used cymbals in their rites. The Greeks employed bells of some kind (*kōdōnes*) in camps and garrison; and the Romans announced the hour of bathing by the *as thermarum*. Great uncertainty prevails as to the introduction of bells into Christian churches. Suetonius relates that Augustus Caesar placed *tinnabula* round the top of the temple of Jupiter Tonans; and it is possible that when basilicas and other buildings came into the possession of the church in the reign of Constantine the Great, the bells belonging to them were readily adapted to the purpose of calling together congregations. The ascription of the first use of bells for church purposes to Paulinus, Bishop of Nola in Campania, appears to rest mainly on the names *Nola* and *Campana*, which are commonly given to bells. *Nola*, however, is a word in use long before the time of Paulinus, and hardly likely to be taken from the name of a city without modification. The derivations of both words are probably not local. Bells appear to have been introduced into France about 550; and Benedict, abbot of Wearmouth, is related to have brought one from Italy for his church about 680. Bells came into use in the Greek Church in the 9th century, and in Switzerland and Germany in the 11th. Most of the bells first used in Western Christendom seem to have been hand-bells. Several specimens, some of them, it is believed, as old as the 6th century, are still preserved in Ireland, Scotland, and Wales. They are made of thin plates of hammered iron, bent into a four-sided form, fastened with rivets, and brazed or bronzed. Perhaps the most remarkable is that which is said to have belonged to St Patrick, called the *Clog-an-cadhachta Phatraic*, or 'The bell of Patrick's Will.' It is 6 inches high, 5 inches broad, and 4 inches deep, and is kept in a case or shrine of brass, enriched with gems and with gold and silver filigree, and was made (as an inscription in Irish shows) between the years 1091 and 1105. The bell itself is believed to be mentioned in the *Annals of Ulster* as early as the year 552. Engravings as well of the bell as of its shrine, with a

history of both, by the Rev. Dr Reeves of Lusk, were published at Belfast (where the relic is preserved) in 1850. The accompanying cut shows an ancient specimen of this type from Brittany. Some of the Scottish bells, of the same primitive type, are figured and described in Dr Joseph Anderson's *Scotland in Early Christian Times* (Rhind Lectures, Edin. 1881). The four-sided bell of St Gall, an Irish missionary who died about 646, is still shown in the monastery of the city which bears his name in Switzerland.

Ancient Bell from Brittany.

Church-bells were suspended either in the steeples or church-towers, or in special bell-towers. They were long of comparatively small size: the bell which a king presented to the church of Orleans in the 11th century, and which was remarkable in its age, weighed only 2600 lb. In the 13th century much larger bells began to be cast, but it was not until the 14th century that they reached really considerable dimensions. The bell 'Jaqueline' of Paris, cast in 1400, weighed 15,000 lb.; another Paris bell, cast in 1472, weighed 25,000 lb.; the famous bell of Ronen, cast in 1501, weighed

10½ tons; 'Great Tom' at Christ Church, Oxford, a faulty bell, cast in 1680, 7½ tons; 'Great Tom' at Lincoln, cast in 1834, 5½ tons; the Great Bell at St Paul's, cast in 1881, 17½ tons; the church of the Sacred Heart at Montmartre, close on 19 tons. Many of these weights have been imperfectly verified, and must be received with reserve. See Gatty's *The Bell* (1848), Stainer's *Great Paul* (1882), North's *English Bells and Bell-lore* (1891), and the present writer's *Church Bells of Suffolk* (1891); with a bibliography of English Campanology.

Associated in various ways with the ancient ritual of the church—insomuch that Mohammedanism (q.v., p. 249) rejects the use of bells and substitutes the muezzin's cry—bells acquired a kind of sacred character. They were consecrated by a complete baptismal service; received names, had sponsors, were sprinkled with water, anointed, and finally covered with the white garment or chrism, like infants. This usage is as old as the time of Aeluin, and is still practised in Roman Catholic countries. Bells had mostly pious inscriptions, sometimes indicative of the widespread belief in the mysterious virtue of their sound. They were believed to disperse storms and pestilence, drive away enemies, extinguish fire, &c. The mediæval inscription, 'Voce mea viva depello euncta noevia,' is still frequently found on bells in the west of England. Among the superstitions usages recorded to have taken place in old St Paul's Church in London, was the 'ringing the hallowed belle in great tempestes or lightnings.' The strange notion that bells are efficacious in dispelling storms is by no means extinct.

Church-bells were at one time tolled for those passing out of the world, in order that the people might put up their prayers for the dying person, as we learn from the *Rationale* of Durandus. The tolling of the passing-bell was retained at the Reformation; nor do the Puritans seem to have objected to the practice, as, for instance, when Dr John Rainolds was dying, 'he expressed by signes that he would have the passing bell tole for him.' But by the beginning of the 18th century, the passing-bell, in the proper sense of the term, had almost ceased to be heard; the tolling took place after the death, instead of before. The practice of slowly and solemnly tolling church-bells after deaths, and before funerals, is still an established usage throughout England. The *Pardon*, *Gabriel*, or *Ave bell*, prior to the Reformation, was rung at morning, noon, or evening, or before or after service, inviting to the recitation of the salutation of the angel Gabriel, *Ave Maria, gratia plena, Dominus tecum*, for purposes of intercessory prayer, or the forgiveness of personal sins. The *Ave bell* was generally one of the ring dedicated to the angel Gabriel, and bearing on it the words of the Annunciation; but any bell might serve the purpose. The *Sanctus* or *Sacring bell*, rung at the *Sanctus* in the mass and at the elevation of the host, was often hung in a place by itself, usually on the gable at the east end of the nave; but a small hand-bell is now usual. *Vesper-bell*, properly the bell that summons to Vespers (q.v.), is usually a popular phrase for a bell rung at evening. Bishop Burnet has recorded the order of Bishop Shaxton of Sarum in 1538, concerning the discontinuance of the custom.

The ringing of the *curfew-bell*, supposed to have been introduced into England by William the Conqueror, was a custom of a civil or political nature, and only strictly observed till the end of the reign of William Rufus, the statute being abolished by Henry I. in 1100. Its object was to warn the public to extinguish their fires and lights at eight o'clock in the evening. The eight o'clock ringing is still continued in many parts of England and Scotland.

Great Bell at Moscow (from a Photograph).

36,364 lb. The largest bell in the world is the Great Bell, Monarch or Czar Bell (*Tsar Kolokol*), of Moscow. It is 19 feet high, 60 feet round the rim, and weighs 198 tons. Cast in 1653, it came cracked out of the foundry, and never was hung. In 1837 it was raised on a granite basement, and makes a kind of chapel, the broken side forming the doorway. Another Moscow bell, the largest in use, weighs 128 tons. The Great Bell at Pekin weighs 53½ tons; the 'Kaiserglocke' of Cologne Cathedral (1887), 14½ feet high, 11½ in diameter, is made of 22 French cannon, and weighs 26 tons 13 cwt.; those of Olmütz, Ronen, and Vienna, nearly 18 tons; that first cast for the New Palace at Westminster (but cracked), 14 tons; that of the Roman Catholic cathedral at Montreal (cast 1847), 13½ tons; 'Great Peter,' placed in York Minster 1845,

On all that belongs to the playing of bells in belfries, the inventive genius of the Netherlands long since arrived at proficiency. In some of the church-towers of that country, the striking, chiming, and playing of bells is incessant; the tinkling called *chimes* usually accompanies the striking of the hours, half-hours, and quarters; while the playing of tunes comes in as a special divertisement. In some instances, these tune-playing bells are sounded by means of a cylinder, on the principle of a barrel-organ; but in others, they are played with keys by a musician. The term *carillons* is used either to the tunes played on bells, or of the suites of bells which yield this kind of music. The tower of Les Halles, at Bruges, is allowed to have the finest carillons in Europe (see BELFERY, CAMPANILE).

Many of the church-towers throughout England, in villages as well as in towns, are provided with peals of bells, the ringing of which is a well-known practice. The number of *changes* or permutations of order that can be rung on a peal, is the *factorial* of the number of bells—i.e. the continued product of all the natural numbers from unity to the number of bells. Thus: 3 bells allow 6 changes; 4 bells, 24; 8 bells, 40,320; 12 bells give as many as 479,001,600 changes. The ringing of peals differs entirely from chiming or tolling.

There is no method of sounding bells equal to the English ringing, when the bell at each pull revolves round a complete circle, and is under the full command of the ringer. This power over the bells makes the sequence of sounds to be regulated at the will of the band of performers, each of whom has his bell, while the leader 'calls' the peal. It is of course necessary that strict order should be observed in arranging the changes, for no unassisted memory would carry a ringer far into the peal. Also, from the nature of bell-machinery, a certain time must elapse between two strokes of the same bell, to allow for its swinging round. The first known writer on the subject is Fabian Stedman, a Cambridge printer, whose *Tintinnologia* was published in 1668. He is said to have printed his changes on slips of paper in his leisure hours, and taught them to his company in the tower of St Benedict, Cambridge. According to his account, there was no idea of change-ringing till the beginning of the 17th century, though there certainly seem traces of it in Udall's *Ralph Roister Doister*, which was written in 1553. Once started, the art made rapid progress, and rings of bells increased from five or six to ten and twelve, the latter being the greatest number ever rung in peal. The simplest peals are those called *Grandsire* on an odd number of bells, and *Bob* on an even number. Thus, changes on seven bells, with the tenor, or great bell, sounded last in each change, are called *Grandsire Triples*; on nine, *Grandsire Cuters*; and on eleven, *Grandsire Cinques*; while on six, eight, ten, or twelve, the more usual methods are respectively *Bob Minor*, *Bob Major*, *Bob Royal*, and *Bob Maximus*. There are, however, a variety of other methods of producing the changes, known as *Oxford Treble Bob*, *Norwich Court Bob*, &c. The muffled peal, which is an invention of later days, is rung with a leather cap over half of the chapper, thus rendering the chimes alternately clear and dull. The effect is very fine.

The general method of making bells has not varied much for centuries, though constant modifications in detail have come into vogue. A *core* of brickwork covered with soft clay is moulded to the intended form of the inner surface of the bell by means of a curved compass called a *crook*, and in a similar way the form of the outer surface is moulded on the inside of the outer mould, or *cope*. The cope is fitted over the core, with a hole left at the

top for the escape of the air, and the metal in a state of fusion is admitted to fill the space intervening between the cope and the core (see CASTING).

The art of casting bells in sequence of sound appears to have been practised after the Conquest, partly by ecclesiastics, and partly by handicraftsmen, who produced bronze lavers, mortars, and after a time cannons, as well as bells. Walter of Odington, a monk of Evesham, in the time of Henry III., has given careful directions for producing a tunable ring, and Sandre (or Alexander) founder of Gloucester, shortly afterwards, was an ecclesiastic. By the end of the 14th century the work appears to have fallen entirely into the hands of laymen; and excellent bells of the period from that time to the Reformation from the foundries in Norwich, Bury St Edmunds, York, Leicester, and other centres, remain in abundance all over England. Nor has the general form of the bell undergone much change since that time. The late 'Tom of Lincoln,' weighing a ton less than the present bell, was cast in the Minster Yard in 1610 by the joint efforts of Henry Oldfield of Nottingham and William Newcombe of Leicester. The bells made by Miles Graye of Colchester, who died in 1649, are deservedly much esteemed by ringers. At the present day the principal foundries in England are those of Messrs Mears & Stainbank, Whitechapel; Messrs Warner & Sons, Cripplegate; and Messrs Taylor & Co., at Loughborough. The foundry at Louvain, lately famous under M. Severin van Aerschoot, has produced many excellent bells, great and small, since the days of the Van den Gheyns, more than three centuries ago. A few medieval bells from Venlo are still found in England. The twelve bells of Christ Church, Oxford, are renowned for their tone; the largest peal in England is that of St Paul's (12 bells, the tenor weighing 64 cwt.).

Rings of bells other than carillons are apparently unknown on the Continent, but in every considerable town fine-toned large bells are to be found, sometimes in sequence though in different churches. Very few old bells remain in France, some districts having been entirely cleared of them in the time of the first Napoleon.

The cost of bells varies according to the current price of tin and copper. It may be taken at from £6 to £7 per hundredweight, so that a ring of twelve bells of the best quality can be obtained for about £1200. The recent invention of tubular bells of steel, patented by Harrington of Coventry, may revolutionise all our notions of ringing, but it is as yet hardly on its trial. The tubes, varying in length from 4 or 5 to 12 or 14 feet, are suspended in a frame in the belfry by means of cords passed through holes in the upper part of each tube, and are struck by a hammer above the point of suspension. The volume of sound is remarkable both for mellowness and fullness; and a ring of eight bells costs from £75 to £130, according to size.

The custom of hanging bells on the necks of horses, cows, and other animals, was in use by the Romans, and still survives in Switzerland and elsewhere. The bells are useful in the dark, or when the animals that wear them are out of sight. The attaching of small spherical bells or crotals to riding and sleigh-horses is common in some parts of Europe and America. These crotals used for this purpose are often exactly like those found in British graves, which were suspended on the spear of the warrior.

Ancient Crotal.

London : Women Take Up Heavy Bell-Ringing as Hobby

Public Ledger Foreign Service
Copyright 1926 Public Ledger Co.

LONDON.—Bell ringing, or, more properly, change ringing, is an art in England which is being taken up by an increasing number of women as a hobby. Heretofore men who manipulate the ropes in church towers have allowed a woman to handle one of the bells now and then, but now the women have mastered the whole business themselves and stand the strain surprisingly well.

Only recently ten women with a woman director rang a quarter-peal at St. Clement Danes Church, which required 49 minutes to complete the 1287 strikes. The next attempt will be given the full peal of Stedman Caters of 5148 strikes, requiring about three hours and a half.

These young women—the one who handles the heaviest bell in a peal of ten, being only 17—organized themselves just before the war into the Ladies' Guild of Change Ringers, and the guild now has a membership of nearly 500. It is increasing in popularity. Eight of them have already accomplished peals of Stedman triples on eight bells with 5040 changes or strikes.

The English people do not believe that a proper effect can be obtained by ringing bells with mechanical devices; there are few, hence carillons in the beautiful towers of England's churches and the peals of bells artistically rung by human effort are a great deal more popular than chimes which usually require some mechanism to gain accurate results.

Virtually all bell ringing follows Stedman, the seventeenth century campanologist, who invented the principle of "caters," which he took from the French word "quatre."

Change ringing on five bells is called "doubles," because two pairs of bells at a time change place with each other; for seven bells the term is "triples," because three pairs change; and for nine bells the term is "caters" (quatre) because four

pairs change with each other. These "odd-bell" changes are generally rung with a "tenor behind," that is the biggest bell is struck at the end of each change.

Stedman's principle consists in the three front bells ringing their six possible changes which the remaining pairs of bells "dodge"—that is, take a step backward in their course "up" or "down". The way the bells change order can best be explained by the following table, which represents the first changes of the caters:

ROUNDS												
1	2	3	4	5	6	7	8	9	0			
2	1	3	5	4	7	6	9	8	0			
3	2	3	1	4	5	6	7	8	9	0		
4	3	4	1	6	5	8	7	9	0			
5	4	3	4	6	1	8	5	9	7	0		
6	5	4	3	1	6	5	8	7	9	0		
7	6	5	3	6	1	8	5	9	7	0		
8	7	6	2	1	6	5	8	7	9	0		
9	8	7	4	2	6	1	8	5	9	7	0	

This looks rather complicated, but it represents only 90 strokes of the 1287 accurately executed by these ten young women. Each one of them had to bear in mind, first, which way her bell was working, "up" from first to last place or "down" from last to first; second, in what place her bell was striking, and, third, what bell or bells were striking immediately before or after hers.

This is simplified, however, by the knack of "rope sight," which is watching the rope being pulled immediately before or after one's own, and is acquired only after long practice. The ringer must keep in mind every moment many rules of the particular method that is being rung. Of course, assistance is given by the director, who stands within the circle made by the ringers and calls out the different changes.

The ringers themselves, however, can hardly enjoy the peals as they pour forth from the tower high above. At the very start it seems like a terrible clatter minus the beautiful tones heard on the outside, and in the case of St. Clement Danes, which is a very old church with a comparatively low tower, the room where the ringers stand actually shakes with vibration.

Change ringing has been an art in England for more than 250 years and has been a hobby of young and old alike. On last New Year's Day a ringer of 84 years took his place in the circle of younger men and accurately handled his bell during a peal that required three hours and a quarter to complete. The youth of the country, however, are not attracted to this hobby in such numbers as they were generations ago; consequently these enthusiastic young women get more opportunities.

SIDNEY THATCHER.

News of Congress for Today and 100 Years Ago

By United Press

CONGRESS 100 YEARS AGO TODAY

Senate: Resumed debate on bill to authorize counsel for Marquis De Maison Rouge to bring suit against the United States to test validity of title to 300,000 acres of land in Louisiana claimed by De Maison Rouse.

House: Referred to a special committee a resolution to increase the duty on imported liquor and to levy an excise tax on liquor distilled in this country; revenue therefrom to be used exclusively for education and internal improvements.

CONGRESS TODAY

Senate: Debates tax bill.

House: Considers District of Columbia legislation.

Appropriations committee considers state and justice, commerce and labor and independent offices appropriation bills.

Naval committee considers aviation legislation.

DR. CHANEY TO GIVE TALK ON GOBI TRIP

His experiences in the Gobi Desert will be discussed by Dr. Ralph W. Chaney on February 23 in Wheeler Auditorium. The lecture will be illustrated and will be delivered at 8 o'clock. Dr. Chaney was a member of the Roy Chapman Andrews expedition into the Gobi last year, returning just after Christmas from the Orient.

Dr. Chaney is curator of the Paleobotanical collection at the University of California and is a research associate of the Carnegie Institution of Washington. This will be the first public address since his return.

Amusements

Berkeley 8450

The *hanging of bells* in dwelling-houses, and ringing them by means of wires from the different apartments, is quite a modern invention: for it was not known in England in the reign of Queen Anne.

More recently, electric bells have been introduced. A galvanic battery requiring attention only at long intervals is used. From this an insulated wire goes to a 'press-button' in a room or lobby, thence to the bell, and back to the battery to complete the circuit. The press-button makes contact when one requires to ring: at other times the current is broken. Beside the bell there is an electromagnet, with an arrangement by which a spring is attracted and released in rapid succession as long as the automatically interrupted current of electricity is passing. This spring carries a knob which strikes the bell as it oscillates to and fro. An index is used when the bell is rung by press-buttons from several rooms.

The best-known earlier campanologists are Hieronymus Magius (Girolamo Magi, an Italian jurist), Paciuchelli, and Stockfleth. Among later English writers, Lord Grimthorpe (Mr Beckett Denison, Q.C.) approached the subject from the side of acoustics, while Messrs Ellacombe, North, Stahl-schmidt, and others have investigated the archaeology of the bells of several districts in England. Schiller's famous *Song of the Bell*, and Poe's *Bells*, may be mentioned as notable amongst poems on the subject.

'BELLS,' on shipboard, is a term having a peculiar meaning, not exactly equivalent to, but serving as a substitute for 'time' or 'o'clock' in ordinary land-life. The division of the day into watches, usually of four hours' duration each, is explained at WATCH. Each half-hour is marked by striking on a bell, in either single or double strokes. The number of strokes depends not on the hour, according to ordinary reckoning, but on the number of half-hours which have elapsed in that particular watch. Thus, 'three bells' is a phrase denoting that three half-hours have elapsed, but it does not in itself show to which particular watch it refers, and may indicate either half-past one, half-past five, or half-past nine in the ordinary watches, or half-past seven in the dog-watch, which is half the period of the ordinary watch. In foggy weather, both steamers and sailing-vessels *when at anchor* sound their bells (see FOG SIGNALS).

Bell, ALEXANDER MELVILLE, was born at Edinburgh in 1819, and there established himself as a teacher of elocution. In 1865 he removed to London, where, two years later, he published his work on *Visible Speech* (q.v.). He had been engaged for more than twenty years in perfecting his phonetic system; and with a view to bring it before the world, he visited the United States in 1868, and delivered a series of lectures, with such success that, in 1870, he removed to America, and finally settled in Washington. He has there published numerous manuals and essays on subjects connected with phonetics; and his *Principles of Phonetics* reached a 5th edition in 1887. Among his earlier writings may be noted an ingenious system of *Steno-Phonography* (1854).—His son, **ALEXANDER GRAHAM BELL**, the inventor of the telephone, was born at Edinburgh in 1847, and was educated at the High School there, and in Germany, obtaining at Würzburg the degree of Ph.D. He removed to America, and at Boston devoted himself to the teaching of deaf-mutes, and to spreading his father's system of 'Visible Speech.' His inventions of the articulating Telephone (q.v.) in 1872-76, of the Photophone (q.v.) in 1880, of the Graphophone (resembling Edison's Phonograph, q.v.) in 1887, and of kindred instruments, have since brought him both wealth and fame.

Bell, ANDREW, D.D., founder of the 'Madras System of Education,' was born at St Andrews, 27th March 1753, and educated at the university of that place. After acting as a tutor in Virginia (1774-81), he took orders in the Church of England, sailed for India in 1787, and within two years was appointed to eight army chaplainships, all of which he managed to hold simultaneously. In 1789 he became superintendent of the Madras Orphanage for the sons of soldiers. Finding it impossible to obtain the services of properly qualified masters, he at length resorted to the expedient of conducting the school by the aid of the scholars themselves. Hence originated the far-famed 'Monitorial System' (q.v.). The state of his health forced him to return to England, where, in 1797, he was pensioned by the East India Company. His pamphlet entitled *An Experiment in Education, made at the Male Asylum of Madras* (1797), attracted little attention, until Joseph Lancaster (1778-1838), a Quaker, commenced to work upon the system, and succeeded in obtaining for it a large measure of public recognition. In 1803 Lancaster also published a tractate on education, recommending the monitorial system, as it was now called, and admitting Bell to be the original inventor of it, an admission which he afterwards discredibly retracted. Lancasterian schools now began to spread over the country. The church grew alarmed, and in 1811 founded the 'National Society for the Education of the Poor,' of which Bell was appointed superintendent, the number of its schools soon increasing to 12,000. He made a journey to the Continent in 1816 to spread his ideas, when he met Pestalozzi. Wordsworth, Coleridge, and Southey, who all had faith in the system, encouraged Bell; but it was found that although powerful service had been rendered to education by its aid, many evils, such as ignorance and inefficiency on the part of teachers, had also resulted from the system. Rector of Swanage till 1809, Bell then was made master of Sherburn Hospital, Durham, and in 1818-19 a prebendary of Hereford and of Westminster. He died at Cheltenham, 27th January 1832. He left (besides a valuable estate) £120,000 for the purpose of founding educational institutions. Half of this was to go to St Andrews, the other half to be equally divided between Edinburgh, Glasgow, Leith, Aberdeen, Inverness, Cnpar, and the Royal Naval School, London. See his *Life* by Southey (3 vols. 1844), and Meiklejohn's *An Old Educational Reformer* (1881).

Bell, SIR CHARLES, an eminent surgeon, whose discoveries in the nervous system have given him a European fame, was born at Edinburgh in 1774, the youngest of five sons of William Bell, a clergyman of the Episcopal Church in Scotland. Three of his brothers became professors, the eldest, Robert, filling the chair of Conveyancing in Edinburgh from 1800 to 1816; John and George Joseph are separately treated. While a mere youth, Charles assisted his brother John in his anatomical lectures and demonstrations. In 1799 he was admitted a member of the Edinburgh College of Surgeons; in 1804 he proceeded to London, where for some years he lectured with great success on anatomy and surgery at the academy in Great Windmill Street. In 1807 he made the discovery, which he established by the publication of his *Anatomy of the Brain* (1811), of the existence of sensory and motor nerves in the brain; his investigations were completed between 1821-29, and included researches on the cranial nerves, which are embodied in his *Nervous System* (1830). These discoveries in physiology have been described as the greatest since Harvey demonstrated the circulation of the

blood. Appointed in 1812 surgeon to the Middlesex Hospital, a few years later he became a member of the Royal College of Surgeons, London; in the former institution he delivered clinical lectures, and raised it to the highest repute. To obtain a knowledge of gunshot wounds, he twice relinquished his London engagements—first after the battle of Corunna in 1809, when he visited Haslar Hospital; next after Waterloo, when he repaired to Brussels, and was put in charge of a hospital. In 1824 he was appointed senior professor of Anatomy and Surgery to the Royal College of Surgeons, London, and subsequently a member of the council. On the establishment of the London University, now University College, in 1826, Bell was placed at the head of their new medical school, but soon resigned, and confined himself to his extensive practice, which was chiefly in nervous affections. In 1829 he received the Royal Society's medal for discoveries in science. In 1831 he was knighted on the accession of William IV. In 1836 he was elected professor of Surgery in the university of Edinburgh. He was a Fellow of the Royal Societies of London and Edinburgh, and a member of some other learned bodies. He was editor, jointly with Lord Brougham, of Paley's *Evidences of Natural Religion*. He died suddenly, 28th April 1842, at Hallow Park, Worcester, where he was staying, and was buried in the churchyard there. Of a cheerful disposition, Bell enjoyed literature and music; fishing was a favourite recreation with him. Among his principal works on surgery and the nervous system are: *Anatomy of the Brain*, 12 plates (1802); *Engravings, explaining the Course of the Nerves* (1804); *Anatomy of Expression in Painting* (1806; posthumous edition, enlarged, 1844); *A System of Operative Surgery* (2 vols. 1807-9); *Gunshot Wounds* (1814); *Anatomy and Physiology of the Human Body* (3 vols. 1816); various papers on the nervous system, which originally appeared in the *Philosophical Transactions*; *Nerves of the Human Body* (1824); *Injuries of the Spine and of the Thigh Bone* (1824); *Institutes of Surgery* (1838); *Animal Mechanics*, contributed to the Library for the Diffusion of Useful Knowledge (1828); *Nervous System of the Human Body* (1830, 4to); *Practical Essays* (1841). *The Hand* (1833) is one of the celebrated *Bridgewater Treatises*. See Pichot's *Vie et Travaux de Sir Charles Bell* (1839), and his *Correspondence* (1870).

Bell, CURRER. See BRONTË.

Bell, GEORGE JOSEPH, an eminent lawyer, a brother of Sir Charles, was born at Edinburgh, 26th March 1770, and passed advocate in 1791. Acknowledged one of the greatest masters of commercial jurisprudence of his time, and in particular of that department of it which relates to the laws of bankruptcy, he was in 1822 appointed professor of Scots Law in Edinburgh University, and in 1823 a member of the commission for inquiring into Scottish judicial proceedings. On the report, drawn up by Bell, was founded the Scottish Judicature Act (1825), prepared by him, which effected many important changes in the forms of process in the superior courts of Scotland; the jury court being abolished as a separate judicature, and conjoined with the Court of Session. Appointed in 1832 one of the clerks of the Court of Session, he was in 1833 chairman of the Royal Commission to examine into the state of the law in general. He also prepared a bill for the establishment of a Court of Bankruptcy in Scotland. A Whig in politics, he was intimate with Lord Jeffrey; he was genial and courteous in manner, and possessed considerable culture. He died 23d September 1843. His principal works are: *A Treatise on the Laws of Bankruptcy in Scotland* (1804), and *Commentaries*

on the Laws of Scotland, which soon ranked with Stair's *Institutes* as a standard authority (1810; 7th ed. 1870); *Principles of the Law of Scotland* (1829; 6th ed. 1872); and *Commentaries on Statutes relative to Mercantile Bankruptcy* (1840).

Bell, HENRY, the father of steam-navigation in Europe, was born at Torphichen Mill, Linlithgow, April 7, 1767. After three years spent as a stone-mason, he was in 1783 apprenticed to his uncle, a millwright. He served under Rennie in London and other engineers, worked in a ship-building yard at Borrowstounness, and in 1790 settled in Glasgow, whence in 1807 he removed to Helensburgh, where his wife kept the principal inn, and he devoted himself to mechanical experiments. As early as 1786 he seems to have conceived the idea of applying steam to navigation; how far he had been anticipated by Fulton and others will be considered under the head of SHIPBUILDING (p. 402). Anyhow, on 12th January 1812, a small vessel, 40 feet in length, called the *Comet*, built under his directions, and with an engine constructed by himself, was launched on the Clyde with success—the first on European waters. Bell died at Helensburgh, November 14, 1830.

Bell, HENRY GLASSFORD, lawyer and man of letters, was born in Glasgow, 8th November 1803. He attended Edinburgh University, studied law, passed as an advocate in 1832, and gained the acquaintance of the ruling literary spirits of that time in Edinburgh. He was appointed a sheriff-substitute of Lanarkshire in 1839; in 1867 he succeeded Sir Archibald Alison as sheriff, and acquired the reputation of being the best Scottish mercantile lawyer of his day. He founded (1828) and was for three years editor of the *Edinburgh Literary Journal*; besides publishing a vindication of Mary, Queen of Scots (1830); *Summer and Winter Hours* (1831); *My Old Portfolio* (1832); and *Romances and Minor Poems* (1866). He died 7th January 1874. See the Memoir by Stoddart (1892).

Bell, SIR ISAAC LOWTHIAN, was born in 1816, and educated at Edinburgh and Paris. After being engaged in extensive chemical works, he founded, with his brothers, the great Clarence iron-smelting works on the Tees. He wrote many papers on metallurgical and chemical subjects; became F.R.S., D.C.L., and an officer of the Legion of Honour; was M.P. for Hartlepool from 1875 till 1880; and was made a baronet in 1885.

Bell, JOHN, of Anternony, a celebrated Asiatic traveller, born in Campsie parish, Stirlingshire, in 1691, studied for the medical profession. In 1714 he went to St Petersburg, and soon after was appointed physician to an embassy from Russia to Persia. In 1719 he was sent upon another to China, through Siberia, from which he returned in 1821. Next year he accompanied an expedition to Persia, and in 1737 to Constantinople, where he settled for some years as a merchant. About 1746 he returned to Scotland, where he died at Anternony, July 1, 1780. His *Travels* were published in 1763, and reprinted in Pinkerton's *Voyages and Travels*. Bell is said to have applied to Robertson for help in writing this work, when the latter recommended *Gulliver's Travels* as a model. Hence, perhaps, Bell's simplicity of style, long regarded as a model for travel-writing.

Bell, JOHN, an eminent surgeon, elder brother of Sir Charles, was born in Edinburgh, May 12, 1763. He studied under Black, Cullen, and Monro *secundus*; commenced in 1786 lecturing at Edinburgh on surgery and anatomy; and between 1793 and 1802 published his *Anatomy*. This was followed by a volume of anatomical drawings, illustrative of the structure of the bones, muscles, and joints, and another illustrative of the arteries.

In 1800 he published a *Memorial concerning Military Surgery*; his *System of Anatomy* (1793-95) was translated into German. Of his *Principles of Surgery* (1801-7) a new edition, by his brother, Sir Charles Bell, appeared in 1826. A long and bitter controversy with Dr Gregory as to the attendance of surgeons at the infirmary led to his exclusion from the same. A fall from his horse in 1816, and consequent ill-health, necessitated a visit to the Continent; and he died at Rome, April 15, 1820.

Bell, JOHN, an American statesman, born near Nashville, Tennessee, February 18, 1797, was admitted to the bar in 1816. He was a member of congress from 1827 to 1841, and was made Speaker in 1834, and Secretary of War in 1841. During this period he became, from an ardent Free-trader, a Protectionist and supporter of the Whigs, and favoured the reception of petitions for the abolition of slavery in the district of Columbia; afterwards (1858) he vigorously opposed the admission of Kansas as a slave state. He sat in the United States senate from 1847 to 1859, and in 1860 was nominated for the presidency by the 'Constitutional Union' party, but received only 39 electoral votes, cast by the states of Tennessee, Kentucky, and Virginia. He afterwards took no active share in politics, and died at Cumberland Ironworks, September 10, 1869.

Bell, JOHN, sculptor, was born at Hopton, Suffolk, in 1811, and exhibited at the Royal Academy as early as 1832, but first became well known by his figure of 'Dorothea' (1841). Among his subsequent works have been statues of Lord Falkland (1847) and Sir Robert Walpole (1854), for the new Houses of Parliament, the Guards' Memorial (1858) in Waterloo Place, and the America group in the Hyde Park Albert Memorial (1873), a replica of which, in terra-cotta, is at Washington. To Bell is due the fashion of carved wooden bread-trenchers. He died in March 1895.

Bell, ROBERT, a busy litterateur, born in 1800 at Cork, in 1828 came to London, and till 1841 was editor of the *Atlas* newspaper. He wrote *The History of Russia and Lives of the Poets for Lardner's Cyclopaedia*, the last volumes of Southey's *Naval History* and Mackintosh's *History of England*, three five-act comedies, two novels, a *Life of Canning*, &c.; but he is best known by his annotated edition of the English poets from Chaucer to Cowper (24 vols. 1824-57). He died 12th April 1867.

Bell, THOMAS, naturalist, was born at Poole, Dorsetshire, in 1792, and in 1813 entered Gny's Hospital, where from 1817 till 1861 he held the post of dental surgeon, whilst also lecturing on comparative anatomy. In 1836 he became professor of Zoology in King's College, London. Elected in 1828 a Fellow of the Royal Society, from 1840 to 1853 he acted as its secretary, and he was also president of the Linnean Society (1853-61), and first president of the Ray Society (1844). He was author of *British Quadrupeds* (1837; 2d ed. 1874), *British Reptiles* (1839), *British Stalk-eyed Crustacea* (1853), and the article 'Reptiles' in Darwin's *Zoology of the Voyage of the Beagle*. In 1832 he commenced a *Monograph of the Testudinata*, of which only eight parts appeared. The plates were reissued in 1872 with letterpress by Dr Gray. He was associated with Professor Owen in the production of *Fossil Reptilia of London Clay* (1849). His, too, was the classic edition of White's *Selborne* (2 vols. 1878). Retiring from practice in his seventieth year, he had purchased the Wakes of Selborne from the grandnieces of Gilbert White, and there, after enjoying a hale and hearty old age, he died March 13, 1880.

Bella, a town of Italy, in the province of Potenza (Basilicata), 17 miles S. of Melfi. Pop. 5830.

Bella, STEFANO DELLA, designer and engraver, was born at Florence in 1610. He was intended for a goldsmith, but early devoted himself to engraving. He executed upwards of 1000 different works—battles, sea-pieces, landscapes, animals, and historical scenes. All are characterised by freedom and delicacy. He died in 1664.

Belladonna, DWALE, or DEADLY NIGHTSHADE (*Atropa belladonna*; *Belladonna*, Ital. 'fair lady,' see below; *atropa*, Gr. *Atropos*, one of the Fates; *dwale*, from A.S., connected with *dull*, from its stupefying effects), a plant of the natural order Solanaceae (q.v.); a herbaceous perennial, growing up every year as a bush, from 2 to 4 feet high, with ovate entire leaves, and bell-shaped flowers of a lurid purple colour, which are fully larger than those of the common harebell, stalked and solitary in the axils of the leaves. It produces berries of the size of a middle-sized cherry, and which, when ripe, are of a shining black colour, and of a sweetish and not nauseous taste, although the whole plant has a disagreeable heavy smell. It is a native of the southern and middle parts of Europe, and is not uncommon in Britain, in the neighbourhood of towns and of ruins, and flowers from June to November. All parts of the plant are narcotic and poisonous, and fatal consequences not unfrequently follow from the eating of its berries, which have an inviting appearance. Its roots have sometimes been mistaken for parsnips. It owes its poisonous properties to the presence of the alkaloid Atropia (q.v.), which is found in all parts of the plant. Large doses either of belladonna or atropia produce dryness of the mouth and throat, dilatation of the pupils, dimness of vision, bright redness or an

Belladonna (*Atropa belladonna*):
a, flower; b, fruit.

actual rash on the skin, quickening of the pulse and respiration, talkative delirium, sometimes convulsions; at a later stage complete paralysis, stupor, and death. The treatment in cases of poisoning consists in the prompt use of emetics; and thereafter in the administration of stimulants, especially strong coffee; vegetable astringents, as tannin; and Calabar bean. In medicinal doses belladonna and atropia are used to relieve spasm, as in colic, whooping-cough; to check excessive secretions—e.g. of sweat, milk, saliva; as an antidote in poisoning by opium, Calabar bean, and prussic acid; and for many other purposes. Local application, in the form of liniment, ointment, or plaster, is often more efficacious, especially in the relief of pain, than internal administration. Belladonna

has been recommended as a preventive of scarlet fever, apparently on the ground of its tendency, when administered in frequent small doses, to produce an eruption and an affection of the throat somewhat similar to those characteristic of that disease; but the evidence of its utility for this purpose is not sufficient to warrant confidence. But perhaps the most important medicinal use of belladonna, and especially its alkaloid, is in the treatment of diseases of the eye (see EYE, DISEASES OF), in many of which its action is invaluable. Its power of enlarging the pupil and giving a glistening appearance to the eyes, has long been used to enhance the female charms; hence the name. For the Common Nightshade, see NIGHTSHADE; for the Woody Nightshade, see BITTERSWEET.

Belladonna Lily (*Amaryllis belladonna*), a very beautiful and nearly or quite hardy species of *Amaryllis* (q.v.), with rose-coloured drooping flowers pencilled with crimson. It is a native of South Africa, has become naturalised in Madeira, and has been cultivated in Europe since the 17th century.

Bellaggio, an Italian village on the promontory that separates the two arms of Lake Como. Its hotels are amongst the finest in Italy, and some of its lovely villas contain valuable art-collections. Pop. 966.

Bellaire, a town and railway terminus of Belmont county, Ohio, on the Ohio River, 5 miles below Wheeling, with manufactures of glass, nails, pig-iron, and agricultural machines. Coal, limestone, and fireclay abound close by. Pop. (1890) 9934.

Bellamy, GEORGE ANNE, an English actress, born most likely at Lisbon in 1727, was the natural daughter of a Quaker school-girl and Lord Tyrawley, by whom she was educated. Having forfeited his favour by going to live with her mother, she secured an engagement at Covent Garden in 1744, and appeared with Quin as Monimia in *The Orphan*. Mrs Bellamy's professional career was brilliant; but her extravagance and profligacy were notorious. In 1785, after many alternations of fortune, a 'free benefit' released her from the debtors' prison, and in the same year she published an 'Apology' for her life (6 vols.). She died in 1788.

Bellamy, JACOBUS, a Dutch poet, born at Flushing in 1757. The son of a Swiss baker, he was indebted for his education to a clergyman and others, who subscribed to send him to the university of Utrecht. He died 10th March 1786, having published three volumes of poetry between 1782 and 1785. Collected editions of his works have appeared at Haarlem in 1826 and 1852, but they omit the finest of all his poems, *Rosje*, a romance remarkable for its pathos.

Bell Animalcules. See VORTICELLA.

Bellarmino, ROBERT, one of the most celebrated Catholic theologians, was born at Montepulciano, near Siena, in 1542. He entered the order of Jesuits at Rome in 1560, and studied theology at Padua and Louvain. Ordained priest in 1569, he was appointed the year after to the chair of theology at Louvain; but he returned to Rome in 1576 to lecture in the Roman College on controversial theology. In 1592 he became rector of the Roman College, was made a cardinal in 1599 against his own inclination, and in 1602 Archbishop of Capua. After the death of Clement VIII., he contrived to escape promotion to the papal chair, but was induced by Pius V. (1605) to hold an important place in the Vatican, where he remained until the time of his death, which took place in the Novitiate-house of the Jesuits,

September 17, 1621. Bellarmine was the chief defender of the church in the 16th century, when its antagonists were mightiest. His ponderous learning, excellent method, and moderation gained him the praise of Bayle, who will not be suspected of any bias in favour of a Jesuit. He gave a conspicuous proof of his fearless honesty in his strenuous opposition to the Pelagian tenets of Molina, a member of his own order. His great work, *Disputationes de Controversiis Christianæ Fidei adversus hujus Temporis Hæreticos* (3 vols. Rome, 1581), is regarded by Catholics as containing the best arguments for their tenets. There can be no question of the merit of his disputations as regards erudition and dialectic dexterity; but as Gerhard, in his *Bellarminus Orthodoxie Testis*, has shown, many of the conclusions are far from being sound or logical. Industry, clearness, and acuteness are the chief merits of Bellarmine's great work; but it is seriously lessened in value by a needless subtlety, forced conclusions, and a very defective exegesis—faults which have long been evident to enlightened Catholic writers themselves. Among his other writings the most able is the *Christianæ Doctrinæ Applicatio*, which was translated into all the European languages. His book, *De Potestate Pontificis in rebus temporalibus*, in which he maintains the supremacy of the pontiff's authority over temporal princes, was condemned as treasonable in Paris and Venice. Pope Urban VIII., at the instigation of the Jesuits, declared Bellarmine to be a 'faithful servant of God'; but his canonisation as a saint has hitherto been opposed. Complete editions of his works have been published at Venice in 1721 (5 vols.), Cologne in 1619 (7 vols.), and Paris in 1874 (12 vols.). His life was written in Italian by the Jesuit Fuligatti (Rome, 1624); an autobiography reaching down to 1613, written in Latin and hitherto withheld by the Jesuits, was edited in 1887, with a German translation, by Döllinger and Rensch. This interesting book somewhat belittles the man, if not the controversialist and theologian.

Bellary, the chief town of Bellary district, 395 miles N.W. of Madras by rail. One of the principal military stations in the presidency of Madras, it is strongly defended by two lines of fortifications. The upper fort, crowning a rock 2 miles in circuit, and 450 feet high, is supplied with water from tanks excavated in the solid granite. Besides the fort and adjacent cantonments, Bellary comprises a native town to the southward, with fine military bazaars. On the north are the public offices, churches, dispensary, school, and railway station. The heat is great, but the town is considered healthy. The cotton traffic and trade of the town has been stimulated by railway connection. Pop. (1891) 59,467.—The district lying between the Nizam's territories and Mysore has an area of 5904 sq. m.; pop. (1881) 736,807, a decrease of 20 per cent. since 1871, due to the famine of 1876-78; (1891) 900,126. Elevated on the east slope of the West Ghats, Bellary has an extremely dry climate. Iron, copper, lead, antimony, manganese, and alum are found; salt and saltpetre are extracted from the soil. Cotton, oil-seeds, hemp, sugar-cane, are the chief products; there are manufactures of cotton and woollen goods, and salt, clintz-stamping, and iron-smelting.

Bellay, JOACHIM DU, a distinguished French poet and prose-writer, the exact date of whose birth is unknown, though an attempt has been made to prove that it happened in 1525, 'as a compensation from nature to France for the battle of Pavia.' He was, next to Ronsard, the most important member

of the famous group of writers known as the *Pleiade*, through whom the enthusiasm and culture of the Renaissance were turned into the channel of French poetry. His *Défence et Illustration de la Langue Française* (1549), in which the aims of the *Pleiade* were explained and vindicated, marks an epoch in French literature. In this work Du Bellay maintained that French prose should be modelled as closely as might be on the Greek and Latin masterpieces; that the earlier French poetry should be set aside as trivial and shapeless; that French verse-writers should thenceforth seek to reproduce the classic stateliness of rhythm and diction in new metrical forms, such as the ode and the sonnet, adopted from their Latin and Italian predecessors. The book contributed greatly to the success of the literary revolution which was effected by the *Pleiade* (see the article *PLEIADE*). In 1549 Du Bellay published a collection of sonnets which led to a brief quarrel with Ronsard on the question of priority in a new field of poetry. He went to Rome as secretary to his relative, the Cardinal du Bellay; but a diplomatic career proved to be uncongenial to him, and he had lost the cardinal's favour and fallen into difficulties before his death in 1560. His poems include a series of sonnets addressed to one *Mademoiselle de Viole*: *Regrets*, *Jeux Rustiques*, and *Les Antiquités de Rome*, translated by Spenser under the title of the *Ruins of Rome*. His verses give singularly graceful expression to the mood, at once pensive and pleasure-loving, which is a characteristic of most writers of the French Renaissance. A few of his poems—among them his best-known piece, the charming *Vaucor*—have been admirably translated by Mr A. Lang in *Ballads and Lyrics of Old France* (1872). The best edition of Du Bellay is that of Marty-Laveaux (1866-67). See also Pater's *Studies in the Renaissance*.

Bell-bird (*Chasmorchelus*), one of the chattering (Cotingidae), found in some of the warm parts of South America, remarkable for the metallic resonance of its cry, which resembles the tolling of a bell, with pauses varying from a minute to several minutes. It is about the size of a jay; the beak is very broad, flat, and wide in its gape; the neck and cheeks are naked. The male is of snow-white plumage, and from his forehead rises a spiral tubular appendage nearly three inches in height when fully erected. The exact anatomical relations of the excrecence are not known. He generally takes his place on the top of a lofty tree, and his tolling can be heard to the distance of three miles. It resounds through the forest, not only at morning and evening, but also at mid-day, when the heat of the blazing sun has imposed silence on almost every other creature. The female is smaller, and brightly coloured. Four species are known.

Bell, Book, and Candle. 'To curse by bell, book, and candle,' is a common phrase referring to a form of excommunication in the Church of Rome, which closed with the words, 'Do to the book, quench the candle, ring the bell.'

Belle-Alliance, the name given by the Prussians to the battle of Waterloo (q.v.), from a farm occupied by the centre of the French army.

Belle de Nuit (Fr., 'beauty of the night'), a name sometimes given to the Marvel of Peru (*Mirabilis jalapa*), sometimes also to certain tropical American and West Indian species of *Convolvulaceae*, with extremely beautiful and fragrant flowers, which open only during the night.

Bellegarde, a second-class fortress of France, in the department of Pyrénées-Orientales, built by Louis XIV. in 1679. It is situated on the Spanish confines on the road leading over the Col de Pertuis from Perpignan to Figueras.

Belle Isle, a British island in the Atlantic, about midway between the NW. of Newfoundland and the eastern point of Labrador. About 21 miles in circumference, it is chiefly known as giving name to the adjacent strait on the south-west, which, with a length of 70 miles, and a greatest breadth of 11 miles, separates Labrador from Newfoundland, and forms the most northerly of the three channels between the Gulf of St Lawrence and the open ocean.—There is another small island of the same name in the Bay of Conception, Newfoundland.

Belleisle, CHARLES LOUIS AUGUSTE FOUQUET, DUC DE, marshal of France, born in 1684 at Villefranche, in Aveyron, was the grandson of the intendant Fouquet. He early distinguished himself in the wars in Italy and the Low Countries against Spain, and afterwards in Poland. In the war of the Austrian succession, he stormed Prague in 1741, and in the following year conducted the marvellously skilful retreat to Eger. In 1757 he was made war minister, and as such introduced important improvements in the French service, reforming the promotion and camp-discipline, and increasing the military schools. He died January 26, 1761, the last of his house.

Belleisle-en-Mer, a French island in the Atlantic, 8 miles S. of Quiberon Point, in the department of Morbihan. It has an extreme length and breadth of 11 and 7 miles, and an area of 330 sq. m. Population, 10,177, chiefly engaged in fishing. Salt is made along the shores, and good pastures are found in the interior. The chief town is Le Palais (pop. 2980), a seaport and fortified place. In the 16th century, the monks of Quimperlé ceded it to Charles IX., who gave it to the Marshal de Retz, that he might fortify it. His successor sold the island in 1658 to Fouquet, intendant of finance, who further improved and strengthened it. His grandson, the celebrated Marshal Belleisle, ceded the island to Louis XV. in exchange for the Comté Gisors (1718). It was captured in 1761 by the English fleet under Keppel, but restored in 1763.

Bellenden (BALLANTYNE), JOHN, of Moray, a Scottish writer in the reigns of James V. and Queen Mary, was born towards the close of the 15th century, and in 1508 matriculated at St Andrews as 'of the Lothian nation.' He completed his education at Paris, where he took the degree of D.D. at the Sorbonne. Bellenden is best remembered by his translation of Boece's *Historia gentis Scotorum*, and of the first five books of Livy (both done in 1533), interesting as specimens of the Scottish prose of that period, and remarkable for the ease and vigour of their style. To each of these works are prefixed poetical *prohemies* or prologues. Bellenden's *Croniklis of Scotland* professes to be a translation of Boece, but it is a very free one, and contains numerous passages not to be found in the original, so that it is in some respects to be considered almost an original work. The author enjoyed great favour for a long time at the court of James, at whose request he executed the translations. As the reward of his performances, he received grants of considerable value from the treasury, and afterwards was made archdeacon of Moray and canon of Ross. Becoming involved, however, in ecclesiastical controversy, he left his country, and, according to Bale and Dempster, went to Rome, where he died about 1550, or as late as 1587. The 'traduction' of Livy was first published in 1822 by Mr Thomas Maitland (afterwards Lord Dundrennan), uniform with his edition of the *Croniklis* in the previous year.

Bellenden, WILLIAM, a Scottish author, who was born, it would seem, at Lasswade, about 1555,

and who died about 1633. Most likely a Catholic, he was a professor in the university, and an advocate in the parliament, of Paris, and was employed in that city in a diplomatic capacity by Queen Mary, and also by her son, who about 1610 conferred on him the appointment of Master of Requests. His *Ciceronis Princeps* (1608), *Ciceronis Consul, Senator, Populusque Romanus* (1612), and *De Statu Prisci Orbis* (1615), he republished in 1616 under the title *De Statu Libri tres*. His crowning labour was *De Tribus Luminibus Romanorum* (1634), the 'three luminaries' being Cicero, Seneca, and Pliny, out of whose works he intended to compile, on the same plan as his previous works, a comprehensive digest of the civil and religious history, and the moral and physical science, of the Romans. 'Bellenden,' says Hallam, 'seems to have taken a more comprehensive view of history, and to have reflected more philosophically on it, than perhaps any one had done before.' His works furnished the materials for Middleton's *Life of Cicero*. Warton first denounced the theft, which was afterwards made clear by Dr Parr in his edition of the *De Statu* (1787).

Bellerophon (originally called HIPPOCHUS) was the son of the Corinthian king Glaucus, and Eurymede, daughter of Sisyphus. Other accounts make Neptune his father. Having accidentally killed the Corinthian Bellerus, he fled to his relative Pretus, king of Argos, whose wife, Antea, fell in love with the young hero. He rejected her offers, whereupon in revenge she poisoned her husband's mind against his guest. Pretus sent him to his father-in-law, Iobates, king of Lycia, with a sealed message, asking Iobates to cause the youth to be slain. The latter, reluctant to do so directly, imposed upon Bellerophon the seemingly impossible task of slaying the formidable Chimera (q.v.). Mounted on the winged steed Pegasus (given to him by Pallas), the hero ascended into the air, and succeeded in slaying the monster with his arrows. He was next sent against the Amazons, whom he also defeated. On his way home he destroyed an ambuscade of Lycians, set by Iobates for his destruction. That monarch now thought it useless to attempt his death, and, as a sort of recompense, gave the hero in marriage his daughter Philonoë, by whom he had three children—Isander, Hippolochus, and Laodameia. Homer relates that he at last drew on himself the hatred of the gods, and wandered lonely through the Aleian field. Pindar relates that Bellerophon on Pegasus endeavoured to mount to Olympus, when the steed, maddened by Jove through the agency of a gadfly, threw his rider, who was stricken with blindness. Bellerophon was a favourite subject in ancient art. His story was dramatised by Sophocles in *Iobates*, and by Euripides in *Sthenobou* and *Bellerophontes*, but not one of the three has come down to us.

Bellerophon, an extinct genus of molluscs, known as an abundant fossil. The shell is spirally coiled in one plane, and the outer margin has a deep notch. About 300 species are known, persisting from the Cambrian to the Carboniferous

Bellerophon tangentialis.

strata. Bellerophon has been baulded about from one division of molluscs to another. Montfort, who established the genus, placed it among cepha-

lopods; till lately it was regarded as a heteropod; now it is placed among fissobranch gasteropods, not far from the common ear-shell, and nearer the family Pleurotomariidae.

Belles-lettres, a term adopted from the French into the English and various other languages. It is commonly used in a somewhat general sense to designate the more elegant or refined departments of literature. In English usage it is synonymous with another vague expression, *polite literature*, including history, poetry and the drama, fiction, essays, and criticism.

Belleville, an eastern suburb or outlying section of Paris, now inclosed by the line of fortifications. It is largely inhabited by the poorest class of workmen, and is notable as a centre of Communist agitation.

Belleville, a thriving town in the province of Ontario, Canada, situated on the Bay of Quinte, Lake Ontario, 48 miles W. of Kingston by rail. It is the seat of Albert University (1857). Pop. 9516.

Belleville, a city of Illinois, U.S., situated in a productive region, 16 miles SE. of St Louis, with coal-beds in the vicinity. Two railways intersect here; and there are manufactures of iron goods, thrashing-machines, and flour. Pop. (1871) 8146; (1891) 15,361, of which a large proportion is German.

Belley, a town in the French department of Ain, 40 miles E. of Lyons. It has a cathedral dating from 889, and fine lithographing stones are procured in the neighbourhood. Pop. 5221.

Bell-flower. See CAMPANULA.

Belligerent. See ENEMY, NEUTRALITY.

Bellingham. See PERCEVAL.

Bellini, the name of a Venetian family which produced several remarkable painters. The earliest was JACOPO BELLINI, who died in 1470. He was a pupil of the celebrated Gentile da Fabriano, and was the first to bring to Venice the skill of Florence. Most of his pictures have perished.—His elder son, GENTILE BELLINI (born probably in 1424; died 1507), was distinguished as a portrait-painter, and also for his processional groups, with fine architectural perspective. Along with his brother, he was commissioned to decorate the council-chamber of the Venetian senate. Mohammed II., having by accident seen some of his works, invited Gentile to Constantinople, employed him to execute various historical works, and dismissed him laden with presents. The 'Preaching of St Mark' is his most famous achievement.—His more celebrated brother, GIOVANNI BELLINI (born about 1428; died 1516), was the founder of the older Venetian school of painting, and contributed greatly to its progress. His works are marked at first by a somewhat hard manner and severe drawing, due to the influence of his brother-in-law, Andrea Mantegna, but gradually increase in warmth and tenderness to the very last. His best works are altar-pieces and devotional pictures, and these rank among the noblest products of the religious art of the world. Besides several examples in Venice and Naples, his 'Circumcision,' now at Castle Howard, his gorgeous 'Feast of the Gods,' at Alnwick Castle, and his 'Blood of the Redeemer,' acquired in 1887 for the National Gallery, are well known. Among his numerous pupils the most distinguished were Giorgione and Titian.

Bellini, VINCENZO, operatic composer, was born at Catania, in Sicily, November 3, 1802. An organist's son, he was sent by a Sicilian nobleman to the Conservatorio of Naples, and there was instructed in composition by Tritto and Zingarelli. His two earliest operas were *Addelson e Salvia* (1824) and *Bianca e Fernando* (1826); the latter

had such success that in 1827 he was commissioned to write a piece for La Scala at Milan. The splendid rendering of this opera, *Il Pirata*, immediately carried the composer's name beyond Italy, and for the short remainder of his life fresh operas appeared almost every year, and were received with unstinted applause by the musical world. Worthy of mention are *I Capuleti ed i Montecchi* (1830); *La Sonnambula* (1831); and *Norina* (1832). Bellini's best and most popular work. In 1833 the composer went to Paris, where he became acquainted with other forms of music beside the Italian. He was received with great applause in London, whither he had accompanied the famous Pasta, for whom he had written *La Sonnambula*. After his return to Paris, he wrote his opera *I Puritani* (1834), which shows the influence of the French school of music, but without servile imitation. At an early age, before the composer had fully developed his powers, his career was cut short by death at his villa in Puteaux, near Paris, 21st September 1835. Bellini was the most genial and original of all the followers of Rossini. His compositions are entirely devoid of either dramatic vigour or musical depth, but, even in their sometimes monotonous melancholy, display such irresistible sweetness as must insure their popularity so long as pleasing tunes and rich melodies are appreciated. See Pongin, *Bellini, sa Vie, ses Œuvres* (Paris, 1868), and Hiller's *Kunstlerleben* (Cologne, 1880).

Bellinzona, or BELLENZ, the chief town of the Swiss canton of Ticino, on the left bank of the river Ticino, 109 miles SSE. of Lucerne by rail. It has still its three old castles, which, with their towers and battlements, give the place a very medieval appearance, but of which only two are now fortified, the third serving as a house of correction. Pop. 2436, mostly Italian-speaking.

Bellman. See SWEDEN, p. 9.

Bellona, the goddess of war among the Romans, probably a Sabine divinity, was described by the poets as the companion, sister, or wife of Mars, and was represented as armed with a bloody scourge, and as inspiring her votaries with a restless enthusiasm in battle. During the war with the Samnites, 296 B.C., the consul Appius Claudius vowed a temple to Bellona, which was erected afterwards in the Campus Martius. In this temple the senate gave audience to embassies from foreign powers, and also to returning consuls, whose claims to a triumph and entrance into the city would have been nullified. The priests of the goddess were styled *Bellonarii*, and at their mystic festivals, especially on the 'day of blood' (March 20), used to gash their own arms and shoulders, and thus to offer their blood.

Bellot, JOSEPH RENÉ, Arctic explorer, was born in Paris, 18th March 1826. A lieutenant in the French navy, he served with distinction in the French expedition against Tamatave in 1845, and in May 1851 he joined the expedition in search of Sir John Franklin, sent out by Lady Franklin. Distinguished by his noble daring and spirit of enterprise, he took part in several explorations; in one of which he discovered Bellot Strait. He was lost in an ice crack in Inglefield's expedition, 21st August 1853. His *Journal* was edited by Lemer at Paris in 1854 (Eng. trans. 1855).

Bellot Strait, the passage on the north coast of North America which separates North Somerset from Boothia Felix, and connects Prince Regent Inlet with Franklin Channel. Its east entrance was discovered in 1852 by Lieutenant Bellot. After four unsuccessful attempts, it was explored for the first time by McClintock on his crowning voyage. It is about 20 miles long, and, at its

narrowest part, about 1 mile wide, running pretty nearly on the parallel of 72°, between granite shores which, everywhere high, rise here and there to 1500 or 1600 feet. Through this funnel both the winds and the waters have full play; the latter, permanent currents and flood-tides alike, coming from the west. A point on the south shore, 71° 55' N., 95° W., is the most northerly point of the North American continent.

Bellows. See BLOWING MACHINES.

Belloy, PIERRE LAURENT BUIRETTE DE, one of the first French dramatists who ventured to introduce on the stage native instead of classical heroes. He was born at St Flour, in Auvergne, in 1727, and educated for the law; but the seductions of the stage proved irresistible, and under the name of Dormont he played for some years at St Petersburg and other northern cities. In 1758 he returned to France to superintend the bringing out of his tragedy *Titus*, trusting that its success would reconcile his family to him. In this, however, he was disappointed, for the piece proved a failure, being only a feeble imitation of Metastasio, and he returned to St Petersburg. In 1762 he again visited France, and obtained a decided success by his tragedy of *Zelmire*. It was followed by *Le Siège de Calais* (1765), *Gaston et Bayard* (1771), and *Pierre le Cruel* (1772). He died at Paris, 5th March 1775. His collected works were edited by Gaillard in 6 vols. in 1779; a selection by Anger in 2 vols. appeared in 1811.

Bell Rock, or INCHCAPE, a reef of old red sandstone rocks in the German Ocean, 12 miles SE. of Arbroath, and nearly opposite the mouth of the Tay. The reef is 2000 feet long; at high water of spring-tides it is covered to a depth of 16 feet, at low water is partly uncovered to a height of 4 feet; and for 100 yards around, the sea is only 3 fathoms deep. It was formerly a fruitful cause of shipwreck, and, according to tradition, the abbot of Aberbrothock (Arbroath) placed a bell on it, 'fixed upon a tree or timber, which rang continually, being moved by the sea, giving notice to the saylers of the danger.' This tradition has been embodied by Southey in his well-known ballad of *The Inchcape Rock*. A lighthouse, 120 feet high, designed by Robert Stevenson and Rennie, was erected in 1807-10, at a cost of £61,331.

Section of Bell Rock Lighthouse.

Belluno (the ancient *Bellunna*), a cathedral city of Venetia, Northern Italy, finely situated on the right bank of the Piave, 42 miles N. of Treviso. It is the capital of a province. Pop. 5190.

Beloit, a city of Wisconsin, U.S., on Rock River, 75 miles SW. of Milwaukee by rail. It has a college (1847), several flour and paper mills, foundries, and manufactories of agricultural implements, &c. Pop. (1870) 4396; (1890) 6315.

Belon, PIERRE, a French naturalist, born in 1518 at Soulletière in Maine, studied medicine at Paris, and in 1546 set out on a journey to Greece, Asia Minor, Egypt, and Arabia. He returned in 1549, and in 1553 published the results of his travels. In April 1564 he was murdered by robbers whilst gathering herbs at a late hour of the evening

in the Bois de Boulogne. Besides his book of travels, Belon wrote several valuable treatises on trees, herbs, birds, and fishes. He was one of the first who established the homologies between the skeletons of different vertebrates; he planted the first cedar in France; and he formed two botanical gardens more than a century before the creation of the Jardin des Plantes. A statue of him was unveiled at Le Mans in October 1887.

Belone. See GAR-PIKE.

Belper, a market-town of Derbyshire, on the Derwent, $7\frac{1}{2}$ miles N. of Derby. It owes its prosperity to the cotton-works of Messrs Strutt, one of whom was in 1856 created Lord Belper. The manufacture of silk and cotton hosiery is also largely carried on; but nail-making has declined. Pop. (1851) 10,082; (1881) 9875; (1891) 10,420.

Belsham, THOMAS, a Unitarian theologian, was born at Bedford, 26th April 1750. The son of a dissenting minister and of a granddaughter of the first Earl of Anglesey, he was educated a Calvinist, and became pastor of an Independent congregation at Worcester in 1778, and head of the theological academy at Daventry in 1781. These offices he resigned in 1789, on embracing Unitarian views, and shortly after received the charge of a new theological academy at Hackney, which collapsed for want of funds in 1796. Before its extinction he succeeded Priestley in his pastoral charge of the Gravel-pit Unitarian Chapel, Hackney, and from 1805 till his death, 11th November 1829, filled the pulpit of Essex Street Chapel. Most of his numerous works are controversial. His doctrine regarding the person of Christ represents the purely 'humanitarian' view, as distinguished from the more nearly Arian sentiments of men like Channing. He published also *Elements of the Philosophy of the Human Mind* (1801); a memoir of his predecessor, Theophilus Lindsey (1812; centenary edition, 1873); *The Improved Version of the New Testament* (1808); and the *Epistles of Paul translated* (4 vols. 1822). See his *Life* by Williams (1833).—His brother, WILLIAM (1752–1827), was an active and voluminous writer of history and political tracts on the side of the Whigs. His principal work, written in a liberal spirit, and in a clear and simple style, was his *History of Great Britain to the Conclusion of the Peace of Amiens* (12 vols. 1806).

Belshazzar, the name of a Babylonian prince mentioned in the book of Daniel as the last Chaldean king of Babylon, slain at the capture of the city by the Medes and Persians. No ancient historian mentions his name as one of the successors of Nebuchadnezzar, but the Babylonian cuneiform inscriptions give the name Bel-sar-uzar as that of the son of Nabonidus, the last king of Babylon (555–538 B.C.), and one of his later inscriptions gives ground for the inference that the son was associated with his father on the throne. According to the book of Daniel he had a divine intimation of his impending fate in the words written by an invisible hand upon the wall, *Mene, Mene, Tekel, Upharsin* (lit. 'numbered, numbered, weighed, and divisions').

Belt, the name given to two straits, the GREAT and the LITTLE BELT, which, with the Sound, connect the Baltic with the Cattegat. The GREAT BELT, nearly 40 miles in length, and varying in breadth from about 10 to nearly 20 miles, divides the Danish islands, Zealand and Laaland, from Fünen and Langeland. The LITTLE BELT divides the island of Fünen from Jutland. It is equal in length to the Great Belt, but much narrower. Its greatest breadth is about 10 miles, but it gradually narrows towards the north, until at the fort of Fredericia it is less than a mile wide; thus the

passage from the Cattegat into the Baltic is here easily commanded. Both the Belts are dangerous to navigation on account of numerous sand-banks and strong currents; and therefore, for large vessels, the passage by the Sound (q.v.) is preferred.

Beltane, BELTEIN, or BEALTAINN, the name of a heathen festival once common to all the Celtic nations, and traces of which have survived to the present day. The name is derived from *tin* or *teine*, fire, and *beal*; *Beil* is understood to be the name of a god not directly connected with the Asiatic Belus, but a deity of light peculiar to the Celts, appearing as Belinus in Ausonius, Tertullian, and numerous inscriptions. The great festival of this worship among the Celtic nations was held in the beginning of May, but there seems to have been a somewhat similar observance in the beginning of November—the beginning and the end of summer. On such occasions, all the fires in the district were extinguished; the *needfire* was then kindled with great solemnity, and from this sacrificial fire the domestic hearths were rekindled.

The earliest mention of the beltane is found in Cormac, Archbishop of Cashel in the beginning of the 10th century. Two fires were lighted side by side, and to pass unhurt between them was wholesome for men and cattle. Traces of this usage existed in the Scottish Highlands even in the 19th century, and it is more than probable that the leaping through the flames which was then practised was a survival of a time when sacrifices of animals and even of human beings were thus offered. At Carnac, in Brittany, and in the Irish South Isles of Aran to the present day, the domestic animals are driven through the flames, and thus obtain immunity from accident and disease throughout the year.

Some scholars have striven to identify the worship of the Celtic Beal with that of the Baal or Bel of the Phœnicians and other Semitic nations. It is unnecessary, however, to go beyond the family of nations to which the Celts belong in order to find analogies either for the name or the thing. Grimm identifies the Celtic Beal not only with the Slavonic *Belbog* or *Bjelbog* (*bel* or *bjel*, 'white,' *bog*, 'a god'), but also with the Scandinavian and Teutonic Balder or Paltar, whose name appears under the form of *Baldag* ('the white or bright day'), and who appears to have been also extensively worshipped under the name of *Phol* or *Pol*. The universality all over Europe in heathen times of the worship of these personifications of the sun and of light through the kindling of fires and other rites, still finds a survival in the periodical lighting of *bonfires*. The more marked turning-points of the seasons would naturally determine the times of these festivals. The two solstices at midwinter and midsummer, and the beginning and end of summer, would be among the chief seasons. The periods of observance, which varied, no doubt, originally, more or less in different places, were still further disturbed by the introduction of Christianity. Unable to extirpate these rites, the church sought to Christianise them by associating them with rites of her own, and for this purpose either appointed a church-festival at the time of the heathen one, or endeavoured to shift the time of the heathen observance to that of an already fixed church-festival. All over the south of Germany, the great bonfire celebration was held at midsummer (*Johannisfeuer*), a relic, probably, of the sun-festival of the summer solstice: throughout the north of Germany, it was held at Easter. It is probable that this fire-festival (*Osterfeuer*) of Ostara—a principal deity among the Saxons and Angles—had been originally held on the 1st or

May, and was shifted so as to coincide with the church-festival now known as Easter.

In Great Britain, St John's Eve was celebrated with bonfires; and Easter had its fire-rites, which, although incorporated in the service of the Roman Catholic Church, were clearly of heathen origin. But the great day for bonfires in the British islands was the 1st of November. Fewer traces of this are found in other countries, and therefore we must look upon it as more peculiarly Celtic.

Belts and Belting. Flexible belts for the transmission of motion in machinery are made of leather, india-rubber, cotton, woven hair, gutta-percha and canvas, and other materials. In so limited a time, indeed, as the three years ending with 1886, patents have been taken out for making belting of most of the well-known textile fibres, including flax, cotton, coir, rhea, and some kinds of wool or hair. Sometimes two or more of these are combined along with wire.

The valuable qualities in a belt are: (1) Proper grip of the surface of the pulley. (2) Strength or capacity to resist strain. (3) Non liability to stretch. (4) Durability. Those tanned with oak bark are the most lasting of leather belts, but much excellent belting is made from leather tanned with other substances, such as the bark of the American hemlock spruce. In order to secure uniformity of stretch, so that a belt will run straight, the strips from the tanned hide require to be cut out and combined with much judgment. These strips are prepared by being stretched by powerful machinery to the utmost tension they will stand without injuring the fibre. They are afterwards joined by riveting, lacing, or cementing and lacing, in such a way as to present an even surface to the pulley. One of the largest leather belts yet constructed was made for a paper-mill at Wilmington, Delaware. It was 186 feet long, 5 feet wide, and weighed 2212 lb. A portion of an English belt almost as large as this was exhibited at Manchester in 1887. Belts 4 feet wide are now not uncommon in America. Experiments made in America show that a belt will transmit about 30 per cent. more power with a given tension when the grain or smooth side of the leather is in contact with the pulley than when the flesh side is turned inward. Carefully made leather belts have been known to last in daily use more than thirty years.

What is called leather chain belting, or leather link belting, is formed of short pieces or links of leather joined together by metal rivets. It is employed for driving dynamos for electric lighting, and for other purposes. Solid woven hair belting is similarly used.

India-rubber belting is formed of several plies of cotton duck or canvas, each overspread with rubber composition, and then subjected to a vulcanising heat. This kind of belting is used to a larger extent in the United States than in Great Britain. It is less easily repaired than leather belting, but rubber bands can be made with only one joint, or even without any joint, which is the weak part of a belt. Rubber belting is easily injured by contact with almost any kind of oil.

Cotton belting, of which there are several varieties, some being waterproof, is now a good deal used both in England and in America.

The following are the breaking strains per square inch of section of several kinds of belts:

Best Leather Belting.....	3,300 lb.
Stitch Stitched Cotton Belting.....	6,800 "
Solid Woven Cotton Belting.....	10,420 "
Superior India-rubber Belting.....	4,000 "

Rubber belting varies very much in strength, according to the quality of the canvas or duck used in its manufacture.

The safe working tension of leather belting does not exceed 330 lb. per square inch of section, or about 41 lb. per inch in width of belting $\frac{1}{4}$ th of an inch in thickness. The other kinds also require a large factor of safety.

The extensive use of belting in place of toothed gear-wheels has long been a feature in American engineering, but a preference for driving belts on account of the reduction of jar and noise, facility of adaptation, immunity from accident, and other advantages, has for some time been extending in other countries. It should be added that ropes are now frequently used where belting was formerly employed. See TRANSMISSION OF POWER.

Belu'chistan, or BALUCHISTAN, a country of Southern Asia, bounded on the N. by Afghanistan, on the E. by Sind, on the S. by the Arabian Sea, and on the W. by the Persian province of Kerman. The frontier towards Afghanistan is seldom anywhere clearly defined, but that towards India is more carefully laid down. Beluchistan, which has a coast-line of over 500 miles, corresponds in general with the ancient Gedrosia, excepting that the latter name appears to have extended to the Indus, while the former nowhere reaches that river. The area is about 106,000 sq. m., and the pop. is estimated at some 400,000. Though it was anciently a part of Persia, yet its modern relations connect it rather with India, more particularly since Sind and Multan have fallen under the dominion of the English. In the bygone ages, the Beluchi Desert formed a barrier for the Lower Indus, constraining every assailant from Alexander downwards to prefer the less barren, though perhaps more rugged route through Afghanistan into the Punjab—a preference strengthened by Alexander's direful experience in returning from the Indus along the coast. Until 1810 Beluchistan was almost entirely a *terra incognita* to Europeans. Most of the country indeed is still unknown, but it has been crossed by several travellers; and the laying of the Indo-Afghan Railway (completed to Quetta, March 1887) through the 90 miles of desert in the north-east, as well as the surveys of the Indo-European Telegraph Company in the south, have established its general features. The surface is generally mountainous, more especially towards the north, where branches of the great Suliman Range, running north and south, rise to a height of 12,000 feet. The ranges in the south generally run east and west, parallel with the coast, and the longitudinal valleys between form the principal thoroughfares, there being no regular routes in the country except those through the Bolan and Mula passes to Quetta and Kelat. Even the bottoms of some of the valleys have an elevation of 5700 feet; and the capital, Kelat, situated on the side of one of them, is 6783 feet above the level of the sea. Large deserts, rendered impassable in summer by sandstorms, and swept in winter by benumbing, piercing winds, occupy hundreds of square miles of the country; and the rivers—unless after heavy rains, when those in the north-east frequently inundate great tracts of country—are inconceivable, few of the streams in the south appearing to be perennial at all. The west is largely a land of drought, with stretches of sand varied by bare hills and treeless valleys. The temperature is one of striking and sudden extremes, 125° F. in the shade having been registered on the coast even in March, although at Kelat, in February, water has been observed to freeze as it was poured on the ground. The pastures, as may be supposed, are poor, so that there are few cattle; sheep, however, as well as mountain goats and antelopes, are numerous. The camel is the ordinary beast of burden; but in the north-west, towards Kerman, serviceable horses, with a marked strain of Arab blood, are bred.

The wild animals include the tiger, leopard, wolf, hyena, ape, wild ass, &c., and fish in great quantities are caught off the coast. Wherever there is a sufficiency of water the soil is productive—the lowlands yielding rice, sugar, cotton, indigo, and tobacco; and the higher grounds, wheat, barley, madder, maize, and pulse. The mountains are bare at the top, and their slopes are scantily wooded as a rule; but in the valleys the almond, olive, and peach grow wild, and even the deserts furnish a useful brushwood. The gardens produce excellent fruits of all sorts, and in the sandy coast-district of Mekran the date is carefully cultivated. The minerals are gold, silver, copper, lead, antimony, iron, tin, sulphur, alum, and sal-ammoniac, and in 1887 valuable petroleum wells were discovered in the north; the manufactures are chiefly confined to carpets, tent-covers of goat's and camel's hair, and rude firearms. The only town is the capital, Kelát (q.v.), with (including suburbs) about 14,000 inhabitants, an old citadel, and a number of badly-built and very dirty houses. There are no seaports, the fishing-villages in the south being mere collections of wretched hovels; but along the surf-beaten, sandy cliffs of the coast some sheltered roadsteads are found. The best of these are Sonmiani Bay, Honara, and Gwadar, the last having a fort and a telegraph station. There is an insignificant inland trade, chiefly monopolised by Hindus.

The inhabitants belong to the distinct races of Brahui and Beluchis. The Brahuïs, who are hospitable and generous, are the aboriginal, dominant, and most numerous race—it has even been proposed to call the country Brahuistan. The Beluchis, praised by some travellers and mis-called by others, are powerful on the borders. Opinions are widely divided as to the origin of the Brahui, many assuming their kinship with the Dravidians of Southern India, although apparently on insufficient grounds. Their language presents no marked affinities, but appears to contain many ancient Hindu words, and echoes the accent of the Punjab dialect. In appearance they are short, sturdy, and strongly built, with round, flat faces, and brown hair. Their dress is a coarse calico tunic, with trousers fastened at the ankles, and a skull-cap with sash of the same colour. The Beluchis are of Iranian descent, with a mingling of Tartar blood, and their language closely resembles the modern Persian; they are both numerically smaller and a more recent element than the Brahui. They are tall, with longer and more prominent features, and are brave, but restless and prone to predatory warfare, in which they frequently show themselves senselessly cruel. Their dress is distinguished from that of the ruling race by a turban and wider trousers not confined at the ankles. The women's attire is very much the same as the men's. Both races are inured to extremes of heat and cold, and are capable of considerable exertion; but the normal life of the Beluchis, at least, is one of laziness and indulgence, broken only by hunting, racing, and athletic contests, although Mr Floyer testifies that he found the Mekrani shrewd, merry fellows, willing to work, and priding themselves on their politeness and integrity. A Beluchi warrior carries a formidable armoury of weapons, comprising either a flint-lock musket or a spear, with sword, dagger, and shield. Both races are Mohammedans of the Sunni sect, but the teaching of the Koran is confused with numberless superstitious beliefs, and polygamy is said to be universal. Besides these two races, there are colonies of Persian descent called Delhwars ('villagers'), who form a vassal class, and the Luri, a sort of Gipsies of possibly Indian origin, who are scattered in single families all over the country. Beluchistan is, in a

somewhat indefinite manner, under the authority of the khan of Kelát, who, with a revenue of about £30,000, maintains an army of 3000 men. This petty sovereign having acted treacherously towards the British during the Afghan campaign of 1839, his royal city was taken by storm. In 1841 it was again captured, for temporary occupation, by the British. In 1877 England obtained by treaty with the khan the right of permanently occupying Quetta (which was annexed, with his consent, in 1887), and of having a political agent at Kelát; and the khan practically became a feudatory of the Indian empire, and placed his territory at the disposal of the British government for all military and strategical purposes, gaining by its moral support a prestige that has made his authority more respected by the semi-independent chiefs of the pastoral tribes. In 1893, the reigning Khan was deposed by the British, and his son peacefully proclaimed in his stead.—See Bellew's *From the Indus to the Tigris* (Lond. 1874), and the works on Beluchistan by Hughes (1877), Macgregor (1882), Floyer (1882), and Oliver (1890).

BRITISH BELUCHISTAN is a chief-commissionership of British India, so constituted in 1887, out of the districts of Pishin, Thal Chotiali, and Sibi, in South-eastern Afghanistan, which had been administered by the British since the war of 1878–81.

Belu'ga, or WHITE WHALE (*Beluga* or *Delphinapterus leucas*), one of the dolphin family, closely related to the narwhal. The body is from 12 to 16 feet in length, of graceful proportions, and remarkable for its creamy-white colour, and for the absence of a dorsal fin, which is represented only by a slight ridge. The flippers are short; the head is arched, and sinks abruptly to the short rounded snout; the teeth are small and conical, comparatively few in number (8 to 10 on each half-jaw), somewhat distant from one another, absent posteriorly, and often falling out in the adults. It is a markedly gregarious animal, associating in droves of both sexes. The female shows great solicitude for her young. These are at first of a bluish-gray colour. The white whales feed on fishes, which they often follow far up the rivers—e.g. the St Lawrence and the Amur. According to Eschricht, they also eat cuttle-fishes. They are fearless sportive animals, and have been successfully kept in aquaria. Their headquarters are round Greenland, but they occur all over the Arctic seas, often going as far south as the St Lawrence. They only rarely appear on British coasts. The Greenlanders capture them in the fiords by means of strong nets, or by harpooning, though the comparatively soft skin often fails to retain the weapon. The flesh is largely eaten, the fat yields very fine oil, the skin is made into leather, and some of the internal membranes are also utilised. This name is also applied to a great Russian sturgeon (the Bielaga or Huso). See CETACEA, DOLPHIN, NARWHAL, WHALE.

Belur', a village of Mysore, 130 miles W. of Bangalore. Known in the Purānas as *Velapura*, locally regarded as the Southern Benares, it is the site of a celebrated temple. Pop. 2917.

Belus. See BAAL.

Bel'vedere (It., lit. 'fine view'), a raised turret or lantern on the top of a house, or a high summer-house in a garden or park, from which to look out on the surrounding country. A part of the Vatican in Rome is known as the Belvedere, and gives its name to the famous statue of Apollo (q.v.). The picture-gallery in the royal palace at Vienna bears the same name. Others are at Warsaw, Prague, and Weimar.

Belvedere (*Kochia salsola scoparia*), an annual belonging to the Chenopodiaceæ (q.v.), a native of

the middle and south of Europe. It has long been familiar in British gardens as an ornamental annual, not upon account of its flowers—for they have no beauty—but of its close pyramidal, rigid form, and numerous narrow leaves, which give it some resemblance to a miniature cypress-tree. It is hence sometimes called Summer Cypress.

Belvisia. See NAPOLEONA.

Belzoni, GIOVANNI BATTISTA, a famous traveller, was born, the son of a poor barber, at Padua in 1778. He was educated at Rome for the priesthood, but soon displayed a preference for mechanical science, and when the French republican troops took possession of the pontifical city, quitted his religious studies altogether. About the year 1800 he visited Holland, and in 1803 came to England. Six feet seven inches tall, for a time he gained a living by exhibiting feats of strength, at first in the streets, and afterwards at Astley's. At the same time, however, he continued his mechanical studies, and exhibited models of hydraulic engines in the large towns of the kingdom. After a sojourn of nine years in England, he went to Spain and Portugal in his capacity of theatrical athlete. From the Peninsula he passed to Malta, and thence to Egypt in 1815, on the invitation of Mehemet Ali, who wished him to construct a hydraulic machine for the irrigation of his gardens near Cairo. Although he succeeded in this undertaking, the design was abandoned by the pasha, and Belzoni was induced by the traveller Burckhardt and Mr Salt, the British consul, to direct his attention to the exploration of Egyptian antiquities. He threw himself with ardour into his new vocation. He removed the colossal bust of the so-called 'Young Memnon' from the neighbourhood of Thebes to Alexandria, and was the first who opened the temple of Abu Simbel. In the valley of 'the tombs of the kings'—Biban-el-Muluk—near Thebes, he discovered several important catacombs containing mummies, and among others, opened in 1817 the celebrated grotto-sepulchre of Seti I., from which he removed the splendid sarcophagus, now, along with the 'Young Memnon,' and other results of Belzoni's labours, in the British Museum. But his greatest undertaking was his opening of the second pyramid of Gizeh, supposed since Herodotus' time to contain no interior chamber. An attempt made on his life caused his departure from Egypt, but previously he made a journey along the coast of the Red Sea, and another to Lake Moeris and the Lesser Oasis, which he erroneously supposed to be that of Siwah (q.v.), in search of the ruins of the temple of Jupiter Ammon. In the course of his explorations he discovered the emerald mines of Zubara and the ruins of Berenice, the ancient commercial entrepôt between Europe and India. In 1819 he returned to Europe, and in 1821 published at London his *Narrative of Excavations in Egypt and Nubia*. In 1821 he opened in London a successful exhibition of his Egyptian antiquities, which he took to Paris in the following year. Becoming restless, he soon afterwards undertook a journey to Timbuktu, in Central Africa. At Benin he was attacked by dysentery, from which he died at Gato, December 3, 1823.

Bem. JOSEPH, a Polish leader of the Hungarian insurgents, was born in 1795 at Tarnov, in Galicia. After thirteen years' military service (1812-25), and after taking an active part in the Polish rebellion of 1830-31, he went to France, where he earned a livelihood by teaching mechanics and mnemonics. In 1848, having failed in an attempt to organise an insurrection in Vienna, he joined the Hungarians, and was intrusted with the command of the army of Transylvania, amounting to

10,000 men. He soon defeated the Austrians in several engagements, announcing his victory over the famous Ban Jellachich in the laconic despatch, *Bem Ban Bum* ('Bem has beaten the Ban'); and finally succeeded, in March 1849, in driving both them and their allies, the Russians, into Wallachia. He then proposed, by amnesties and general mild rule, to gain the adherence of the German and Slavonic population; but his propositions were not entertained by Kossuth and the Hungarian commissariat. After expelling the troops under Puchner from the Banat, Bem returned into Transylvania, where the Russians had defeated the Hungarians. Here he was defeated in a battle near Schässburg, where he was opposed to three times the number of his own troops. At Kossuth's request he now hastened into Hungary, and took part in the unfortunate battle near Temesvar. Retreating into Transylvania, he defended himself for some days against a vastly superior force, and then made his escape into Turkey, where he embraced, from political motives, the profession of Islam, and, as Amurat Pasha, obtained a command in the Turkish army. In February 1850 he was sent to Aleppo, where, after suppressing the sanguinary insurrection of the Arabs against the Christian population, he died of fever, December 10, 1850. Bem was distinguished as a general by promptness and courage, and his personal kindness made him popular with his followers.

Bembato'ka, BAY OF, a safe and commodious bay on the NW. coast of Madagascar, in 16° S. lat. and 46° E. long. The river Betsiboka, with the Ikiopa, drain into the bay; the former, which is about 300 miles long, is navigable for small steamers for about 90 miles. Mojanga, on the north side of the bay, is the second town in the island, with about 14,000 inhabitants, Bembatoka being but a village.

Bembex (i.e. 'whirl'), a genus of solitary sand-wasps (Sphegidae), represented by numerous species in most parts of the world. They are roughly wasp-like in appearance, with broad heads and very large eyes, and make a loud buzz during their rapid flight. The female bembex burrows a hole in the sand, and there deposits her eggs, but before closing it up collects a store of flies, on which the larvæ at first subsist. See WASP.

Bembo, PIETRO, one of the most celebrated Italian scholars of the 16th century, was born in Venice, May 20, 1470; having studied at Padua and Ferrara, he early devoted himself to polite literature. He edited the Italian poems of Petrarch, printed by Aldus in 1501, and the *Terzerime* of Dante, 1502. In 1506 he proceeded to the court of Urbino, where he resided until 1512, then went to Rome, and was made secretary to Pope Leo X. On the death of that pope, Bembo returned to Padua, where he became a liberal patron of literature and the arts, as well as a prolific writer himself. In 1529 he accepted the office of historiographer to the republic of Venice, and was also appointed keeper of St Mark's Library. In 1539 Bembo, who had taken only the minor ecclesiastical orders, was unexpectedly presented with a cardinal's hat by Pope Paul III., who afterwards appointed him to the dioceses of Gubbio and Bergamo. He died January 18, 1547. Bembo united in his character all that is amiable. He was the restorer of good style in both Latin and Italian literature. His taste is said to have been so fastidious with regard to style, that he subjected each of his own writings to forty revisions previous to publication. Some of them are marred by the licentiousness of the time. Among his works may be mentioned the *Rerum Veneticarum Libri XII.* (Venice, 1551; Italian ed. 1552); his little

treatise on Italian prose, which marked an era in Italian grammar; *Gli Asolani*, a dialogue on Platonic love; *Rime*, a collection of sonnets and canzonets; and his Letters, Italian and Latin. His *Tutte Opere* were published at Venice in 4 vols. in 1729, and often since.

Bembridge Beds, a division of the Oligocene or Upper Eocene strata, resting on the St Helen's, and capped by the Hempstead series, are principally developed in the Isle of Wight. Edward Forbes arranged them in four divisions: (1) The upper marls and laminated gray clays, which form the basement bed of the 'black band,' the lowest member of the Hempstead series. They are distinguished by the abundance of *Melania turretilsimus*. (2) Unfossiliferous mottled clays, alternating with fossiliferous marls and clays, whose characteristic organisms are *Cerithium mutabile* and *Cyrenia pulchra*. (3) The oyster-bed, consisting of greenish marl, and containing immense quantities of a species of oyster (*Ostrea vecdensis*), accompanied with *Cerithia*, *Mytili*, and other marine mollusca. (4) The Bembridge limestone, generally a compact, pale-yellow, or cream-coloured limestone, but sometimes vesicular and concretionary, and containing occasionally siliceous or cherty bands. This is interstratified with shales and friable marls. All the beds are fossiliferous, containing numerous land and fresh-water shells. One bed is composed almost entirely of the remains of a little globular *Paludina*. Shells of *Lymnea* and *Planorbis* are abundant, and are accompanied with the spirally striated nucleoli of two species of *Chara*, water-plants which have been well preserved because of the large quantity of lime which enters into their composition. In this division have been found the mammalian remains of the species of *Pakiotherium* (q.v.) and *Anoplotherium* (q.v.), which characterise the gypseous deposits of Montmartre.

Bemersyde, an estate with an old mansion, in Berwickshire, near the Tweed, $3\frac{1}{2}$ miles E. of Melrose. It has been held since the 12th century by the Haigs, who form the subject of an excellent monograph by John Russell (Edin. 1881).

Ben (Heb. and Arab., 'son'), often used in connection with the father's name to form Jewish and Arabic personal names, and consequently used, owing to the lack of family-names among the Semitic peoples, to form patronymics—thus Ali Ben Hassan = Ali, son of Hassan. The Hebrew form *Ben* is familiar to us from its use in Bible names—e.g. Benhadad, 'the son or worshipper of Hadad' or Adad, the chief idol of the Syrians; Benoni, 'son of my pain'; Benjamin, 'son of the right hand,' &c. Similarly, many Jews have formed with this prefix new family-names, as Benary = the son of Ari, analogous to English names in *-son*. The Arabs, Persians, and Turks often make the prefix into *Ibn* (*Ebn*); the Jews, under Arabic influ-

ences, *Aben*, *Aven*, as in Aben Esra. The plural, *Beni*, is found in the names of many Arab tribes—as Beni Omayyah, 'the sons of Omayyah,' the family known in history as the Omniades; and sometimes in the names of places—as Beni-Hassan (see BENI-ISRAEL). The corresponding word in Aramaic is *Bar*, as in Simon Bar-jona.

Ben, or BEINN, the Gaelic and Irish form (Welsh *Pen*) of a Celtic word signifying 'mountain' or 'mountain head.' It occurs, usually as a prefix, in the names of a great many mountains and places within the British Isles, as *Ben Nevis*, *Ben Macdui*, The Twelve *Pins*, *Pennigant*, *Penzance*; and it appears in many continental names, as the *Penine* Alps, the *Apennines*, and *Pindus*.

Ben, OIL OF, a fluid fixed oil, obtained from the seeds of a tree found in India and Arabia, and known as the Horse-radish Tree (*Moringa pterygosperma*). The seeds are called Ben Nuts, and are roundish, with three membranous wings. The oil has several properties which make it of special value to perfumers and watchmakers. When exposed to cold, it deposits a white flaky matter; and when this is removed, an oil is left which is most suitable for watches owing to its non-liability to freeze. Oil of ben is also used to extract the odorous principles from flowers; and as it is not liable to turn rancid, it is much prized in the manufacture of perfumes, although its frequent adulteration with other oils has tended to restrict its use. See HORSE-RADISH TREE.

Benares (*Bandras*), the most sacred city of the Hindus, and one of the principal towns of North India, situated on the left or northern bank of the Ganges, 420 miles by rail from Calcutta, and 74 from Allahabad. It is the largest city in the North-west Provinces (excluding Oudh). It skirts the Ganges for 3 miles, and the high bank is lined continuously with broad flights

The Burning Ghat, Benares.

of stairs or *ghâts*, leading to the innumerable temples and large substantial houses, which present towards the river an imposing array of towers and pinnacles and richly carved façades. The river takes a great crescent-like sweep at this point, and the view of the city is one of the most striking in the world. Benares, however,

is disappointing internally, the streets being mere narrow lanes between the lines of tall, dismal houses. But the crowds of priests and pilgrims on the ghats and at the temples, the sacred bulls wandering at large, and even the wares exposed for sale, all point to the religious character of the place. Among the chief buildings are the Nepalese Temple, Aungmye's mosque, with its two minarets 147 feet high; Raja Jai Singh's observatory; the Gopal Mandir, wealthiest of all the temples; the Bishwar or Golden Temple of Siva, the holiest of all; and the famous Monkey Temple, in the suburbs. Other points of special interest are the well of Mani Karniki, formed of Vishnu's sweat; the Juana-vapi, or 'pool of knowledge'; and the Lat Bhairo, a portion, it is believed, of one of Asoka's pillars. To bathe in the Mani Karniki is to be cleansed from all sins for time and eternity. At the Burning Ghat the bodies of Hindus are reduced to ashes. The city counts 1450 Hindu temples or shrines, most of them small, and 272 Mohammedan mosques. In the European part of the city there is the Government College, a large freestone structure, with 700 students; the Prince of Wales's Hospital; and a town-hall. By far the most important European work is the new Dufferin Bridge, opened on the 18th of December 1887, on the East Indian and Oudh and Rohilkhand railways. It crosses the Ganges in sixteen spans, having a total length, not including approaches, of 3518 feet. Formerly there was only a bridge of boats, which had to be withdrawn during the floods. Benares draws immense revenues from the thousands of pilgrims who visit it from all parts of India. It has a considerable trade, not only in country produce, but in English goods, jewelry, and precious stones. Its brass ware, kinoh or gold-cloth, and bequeathed toys are famous. Pop. (1881) 191,025, of whom 147,230 were Hindus, 45,529 Mohammedans, and 266 Christians; (1891) 222,420, of whom 160,000 are Hindus. A city of great antiquity, Benares (Sansk. *Vārāṇasī*) was for 800 years the headquarters of Buddhism. In the 4th century B.C. it reverted to the ancient faith, of which it has ever since been the metropolis. It has been in the hands of many temporal rulers—the Rajput princes, the Mogul emperors, the Oudh nawabs—being ceded by the latter to the English in 1775. There was a rising here during the Mutiny in 1857, but it was promptly dealt with, and the constant passage of troops from Calcutta to the north kept the city free from disturbance. The western suburb of Sikol (Seerole) contains the military cantonments and European quarter; the suburb of Sighra is the seat of most of the missionary institutions. The district has an area of 998 sq. m. The climate is the hottest and dampest in the North-west Provinces, the mean temperature being 77°, and the annual rainfall about 40 inches. The soil is very fertile. The population is over 900 to the square mile.

Benaventé, a town of Spain, in the province of Zamora, on the western bank of the Esla, 34 miles N. from Zamora. It is overlooked by a huge half ruined castle, and is now a dull and poverty-stricken place, built chiefly of mud cottages. It was here that Moore's retreat commenced, 25th December 1808. Pop. 4507.

Benbecula, one of the Hebrides or Western Isles of Scotland, between North and South Uist, 20 miles W. of Skye, and belonging to Inverness-shire. Measuring 6 or 7 miles either way, it is nearly 35 sq. m. in area, low and flat, and consists chiefly of bog, sand, and lake, resting on a substratum of gneiss rock, with a very broken coastline. Nearly three-fourths of the area are under crofts and farms. Pop. 1534.

Benbow, JOHN, admiral, was born in 1653, the son of a Shrewsbury tanner. He entered the navy as a master's mate in 1678, but it was as captain of a merchantman that he first distinguished himself in a bloody action with Sallee pirates (1686). After the Revolution he re-entered the navy, and received his first commission as third-lieutenant, June 1, 1689; but before the close of the same year he was appointed in succession captain to three men-of-war, and by 1696 had risen to be rear-admiral. The most memorable of all his exploits was his last, where his stubborn valour contrasted nobly with the disloyal behaviour of his captains. Off Santa Marta, in the West Indies, on 19th August 1702, he came up with a superior French force under Du Casse. For four days he kept up a running fight with the enemy, almost deserted by the rest of his squadron. On the morning of the 24th his right leg was smashed by a chain-shot. His officers consoled with him. 'I had rather have lost them both,' said the sturdy admiral, 'than have seen this dishonour brought upon the English nation. But, hark ye—if another shot should take me off, behave like men, and fight it out!' As soon as his wound was dressed he was carried to the quarter-deck, and directed the fight while it lasted. The enemy sustained severe loss; but the behaviour of the other captains, who actually refused to obey the admiral's signals, made the contest hopeless, and Benbow sailed away to Jamaica. He died of his wound at Port Royal, on the 4th November. The recusant officers were tried by court-martial, and two captains were shot. Cowardice is none so common among English naval officers that we can rest content with that as an explanation of the strange conduct of Benbow's captains in their unmitigated disobedience to his orders. Indeed, it is more than likely that their disaffection was to a large extent a personal matter, and that the 'honest, rough seaman,' by his overbearing and bullying nature, had made himself as hateful to his higher officers as he was popular with his crew for his off-hand manners and personal courage.

Bench, the high seat of the court-room or chamber where judges sit to administer the laws, or the platform on which the chairs for the judges are placed. The court of King's or Queen's Bench (q.v.) was originally so called because in it the sovereign sat in person when he administered justice. The court of Common Pleas was also called Common Bench. The term bench is also applied in America as in Britain to the judges themselves as a class; thus, we speak of the *bench* and *bar*. It has likewise, popularly and conventionally, an ecclesiastical application, the bishops of the Church of England being, as a body, sometimes designated by it; hence the expression, 'Bench of Bishops.' So also in the Episcopal and Methodist-Episcopal churches in the United States. 'Benchers' is the time-honoured name of the governing bodies of the four Inns of Court (q.v.). See also BANC.

Bench-warrant is a warrant issued by the court before which an indictment has been found to arrest the accused, that he may appeal and find bail for his appearance at the trial. It is used extensively in the United States to bring into court persons who have neglected to obey an order of court, such as delinquent jurymen.

Bencoolen, capital of a Dutch residency on the SW. coast of Sumatra. Owing to the surf and coral reefs, landing here is difficult; the site is low and swampy, and the houses are mostly built on bamboo piles. A lighthouse has been erected; and the town is defended by a fort. Rice, coffee, maize, sugar-cane, the cocoa-nut, and other

fruits are grown; pepper and camphor are the chief exports, but trade has declined. Bencoolen was founded by the English (1686), but was ceded to the Dutch by the London treaty of 1825. Pop. of town, 12,000; of residency, with an area of 9682 sq. m., 158,200.

Bend, in Heraldry, one of the figures known as Ordinaries, consists of the space contained between two parallel lines crossing the shield diagonally from dexter chief to sinister base (fig. 1). It is said to occupy a fifth part of the shield unless charged, when it occupies a third part. Its diminutives are the *Bendlet*, which is half its width (fig. 2), the *Cotise* (q.v.), one-fourth (generally borne in pairs flanking the bend), and the *Ribbon*, one-eighth of its width. In early Heraldry the bend was used as a difference or mark of cadency as well as an original bearing.

The *Bend-sinister* is an occasionally occurring variety of the bend, drawn from sinister chief to dexter base (fig. 3). The *Scarpe* is its diminutive; and that well-known mark of illegitimacy, the *Baton-sinister* (q.v.), is also so accounted.

Charges placed in the direction of a bend are said to be *bendwise*, and when a bend is charged with other figures, the charges on it are understood to be placed bendwise. The term *in bend*, when applied to several charges, differs from *bendwise*, in so far as it has reference to the relative position of the charges, not the direction in which each charge lies, as will be understood from the figure,

where the three crosses botonné are placed *palewise in bend* (fig. 4).

A field divided by a diagonal line in the direction of a bend is said to be *parted per bend* (fig. 5).

Bendy is a term applied in Heraldry to a field divided into four or a larger even number of parts by lines drawn diagonally, or in the direction of a bend

as in the figure, Bendy of six argent and azure.

Benda, GEORG, the most distinguished of a notable musical family, born at Jungbunzlau, in Bohemia, in 1721, and distinguished as a pianist, violinist, and composer, died at Köstritz in 1795. He was bandmaster to the Duke of Gotha (1748-87), and in this period produced several operas and cantatas, such as *Ariadne auf Naxos* and *Medea*.

Bendemann, EDUARD, painter, was born in Berlin in 1811, and studied under Schadow. As early as 1832 his great picture of the Captive Jews was exhibited at Berlin, and in 1837 he gained the gold medal at Paris. In 1838 he was appointed professor of the Academy of Art at Dresden. Here he was intrusted with the execution of the larger frescoes in the palace, and on these his fame chiefly depends. In 1858 he succeeded his

father-in-law as director of the Düsseldorf Academy, a post which he held until 1867. He afterwards produced several large canvases and frescoes, some of which are among his best works. He died 27th December 1889.

Bender, a strongly fortified town, with a citadel, in the Russian province of Bessarabia, on the right bank of the Dniester, 82 miles NW. of Odessa by rail. Population, 44,684, including many Armenians, Tartars, Moldavians, and Jews. The principal industries are the manufacture of bricks, stoneware, paper, and leather, with agriculture, fishing, and mining. The local trade is important. In 1770 the Russians captured the place, and put the garrison and inhabitants, then amounting to about 30,000, to the sword. It was restored to the Turks in 1774, but was again stormed by the Russians in 1789, 1806, and 1811. Finally, by the peace of Bucharest in 1812, the town, with the whole of Bessarabia, was formally ceded to Russia. Charles XII. of Sweden lived from 1709 till 1712 at Varnitza, near Bender.—Bender Abbas is another name for the town of Gombroon (q.v.).

Ben'digo, a county of the Loddon district, Victoria, has the river Loddon on its W. boundary, and the Campaspe on the E. Area, 1949 sq. m.; pop. 52,756. The chief town, Bendigo, formerly known as Sandhurst (q.v.), is often reputed as only second in importance to the capital of the colony. Near it rich alluvial deposits of gold were discovered in 1851; now quartz-mining operations in the district employ about 6000 persons. The county is traversed by the main line of railway between Melbourne and Echuca.

Benedek, LUDWIG VON, an Austrian general, born in 1804 at Oedenburg, in Hungary. He entered the army in 1822, and on the occasion of the insurrection of Galicia in 1846, had several opportunities of distinguishing himself. In 1847 he commanded a regiment in Italy. He distinguished himself at the taking of Mortara, and in the battle of Novara. In 1849 he commanded in Hungary, and took an important share in several battles, being twice wounded. At the close of the Hungarian campaign, he was ordered again, high in command, to Italy. In the Italian campaign of 1859, Benedek commanded the eighth corps of the Austrians. At Solferino he drove back the Piedmontese with great slaughter. He was governor of Hungary in 1860, and soon after commander-in-chief in Venice. In 1866 he commanded the northern Austrian army in the war with Prussia; but shortly after the defeat of Sadowa, he was superseded, and brought to a court-martial. Though its proceedings were quashed by the emperor, Benedek never recovered from the savage criticism to which his vanquished and mortified countrymen subjected him; and he retired to Graz, where he died April 27, 1881.

Benedetti, VINCENT, COUNT, a French diplomatist, born in 1817 at Bastia, in Corsica, was appointed in 1855 director of political affairs to the foreign minister, and in this capacity edited the protocols of the Congress of Paris in the following year. He was appointed ambassador at Turin in 1861, and at Berlin in 1864. Benedetti drew up the draft of a secret treaty between France and Prussia in 1870; and it was he who made at Ems the demand about the Hohenzollern candidature that led to the war. In *My Mission in Prussia* (1871) and *Studies in Diplomacy* (Eng. trans. 1895) he defends his own policy and throws all blame on Bismarck. He latterly practised at the bar of Ajaccio in Corsica, and died 25th March 1900.

Benedi'cité, or the Song of the Three Children, a canticle from the Apocrypha forming part

of the prayer of Abednego in the fiery furnace. It was sung in the Christian Church as early as the time of St Chrysostom, and is used in the Anglican Church in the morning services when the *Te Deum* is not sung.

Benedict is the name of fourteen popes. Of these only the following are historically important enough to deserve special mention: **BENEDICT VIII.**, son of Count Gregory of Tuscoli, was elected in 1012, but was driven from Rome by the anti-pope Gregory. In 1014 he was restored to the papal chair by the Emperor Henry II., and afterwards defeated the Saracens, and took from them, with the help of the Pisans and Genoese, the island of Sardinia; and also various places in Apulia from the Greeks, by the help of Henry. He distinguished himself as a reformer of the clergy, and interdicted, at the synod of Pavia, both clerical marriage and concubinage. He died in 1024.—**BENEDICT IX.**, a nephew of the preceding, obtained the papal throne by simony in 1033, at the age of 18; but in 1038 the Romans rose in indignation, and banished him on account of his almost unexampled licentiousness. By aid of bribery he was several times reinstalled, and as often formally deposed, only to return again by the same means. The Emperor Henry III., to remove such gross scandals from the church, deposed all the three popes—Benedict, Sylvester, and Gregory, and caused Suidger, Bishop of Bamberg, to be elected as Clement II.; but on his death, in 1047, the deposed Benedict IX. again corruptly regained the papal see, and held it for eight months, when he was displaced, first by Damasus II., and afterwards by Leo IX. He died in the convent of Grotta Ferrata in 1056.—**BENEDICT XIII.** is a title assumed by two popes, *Peter de Luna*, a Spaniard, chosen by the French cardinals in 1394, and recognised only by Spain and Scotland up to his death in 1424; and *Vincenzo Maria Orsini* (1724–30), a learned and well-disposed man, of simple habits and pure morals, who unfortunately yielded himself to the guidance of the greedy and unscrupulous Cardinal Coscia, who greatly abused the confidence reposed in him. Benedict always exhibited great moderation in politics, and an honourable love of peace, and was instrumental in bringing about the Seville treaty of 1729. During this pontificate, a remarkably large number of saints, chiefly from the monastic orders, were added to the calendar.—**BENEDICT XIV.** (Prospero Lambertini), the most worthy to be remembered of all the pontiffs so named, was born at Bologna in 1675. Before his elevation, he had distinguished himself by extensive learning, and by marked ability in the lower offices. Succeeding Clement XII., he began his pontificate, in 1740, with several wise and conciliatory measures; founded chairs of physic, chemistry, and mathematics in Rome; revived the academy of Bologna, and instituted others; dug out the obelisk in the Campus Martius, constructed fountains, rebuilt churches; caused the best English and French books to be translated into Italian; and in many other ways encouraged literature and science. His piety was sincere, enlightened, and tolerant, and his doctrines were well exemplified in his practice. He was extremely concerned for the morals of the clergy, and established a board of examiners for all candidates to vacant sees. Two important bulls were promulgated by him, denouncing such accommodation of Christian doctrines and rites to heathen beliefs and usages as the Jesuits had practised in the East. The only accusation brought against him by his Roman subjects was 'that he wrote and studied too much, but ruled too little,' or left affairs of business too much in the hands of the Cardinal Valentine. After a painful illness, Benedict XIV. died May 3, 1758.

Benedict, ST, the founder of Western monachism, was born of a wealthy family at Nursia, near Spoleto, in 480 A.D. At an early age he was sent to the schools of Rome, but soon grew dissatisfied with the sterile character of the instruction dispensed. The world to the boy seemed full of distractions, impurities, and ignorance; it was difficult to resist, by the ordinary safeguards of virtue, the colossal evils with which men were environed; only, therefore, in the devotions of religion, in the holy silence of solitary meditation, did Benedict see a safe refuge from the sins of the time, and the possibility of realising a spiritual strength which would enable him to stem the flood of corruption. He resolved to leave the city, and betake himself to some deep solitude where the murmur of the world would be inaudible, and alone in the rocky wilderness wrestle with his own nature, until he had conquered it and laid it a sacrifice on the altar of God. In pursuance of this resolution, when he had only reached the age of fourteen, he departed from Rome, accompanied for the first 25 miles by the nurse whom his parents had sent with him as an attendant. He then left her, and retired to a deserted country lying on a lake, hence called *Sublaqueum* (now Subiaco). Here, in a cavern (which afterwards received the name of the Holy Grotto), he dwelt for three years, until his fame spread over the country, and multitudes came to see him. He was now appointed abbot of a neighbouring monastery, observing, or rather neglecting, the oriental rule; but soon left it, as the morals of the half-wild monks were not severe enough. This, however, only excited a livelier interest in his character, and as he lived in a period when the migration and interfusion of races and nations were being rapidly carried on, he could not fail to draw crowds of wanderers about him. Wealthy Romans also placed their sons under his care, anxious that they should be trained for a spiritual life. Benedict was thus enabled to found twelve monasteries, over each of which he placed a superior. The savage Goths even were attracted to him, and employed in the useful and civilising practice of agriculture, gardening, &c. He now sought another retreat, and, along with a few followers, founded a monastery on Monte Cassino, near Naples, afterwards one of the richest and most famous in Italy. Here he extirpated the lingering relics of paganism, and had his celebrated interview with Totila, king of the Goths, to whom he spoke frankly and sharply on his errors. In 515 he is said to have composed his *Regula Monachorum*, in which he aimed, among other things, at repressing the irregular and licentious life of the wandering monks, by introducing stricter discipline and order. It eventually became the common rule of all Western monachism. The monasteries which Benedict founded were simply religious colleges, intended to develop a high spiritual character, which might beneficially influence the world. To the abbot was given supreme power, and he was told to acquit himself in all his relations with the wisdom of God and of St Benedict. The discipline recommended is milder than that of oriental monachism with regard to food, clothing, &c.; but enjoins continual residence in the monastery, and, in addition to the usual religious exercises, directs that the monks shall employ themselves in manual labours, imparting instruction to youth, copying manuscripts for the library, &c. By this last injunction, Benedict, though this was not directly intended, preserved many of the literary remains of antiquity; for the injunction, which he gave only with regard to religious books, was extended afterwards to many secular productions. It is remarkable that the founder of the most learned of all the monastic orders was himself so

little of a scholar that St Gregory the Great described him as being '*scienter nesciens, et sapienter indoctus*'—learnedly ignorant, and wisely unlearned. St Benedict died March 21, 543.

Benedict, SIR JULIUS, a musician and composer, German by birth, but after 1836 resident in England. Born November 27, 1804, at Stuttgart, where his father was a Jewish banker, he studied first under Hummel at Weimar, and afterwards under Weber at Dresden. On Weber's recommendation, he was, in 1824, made musical director of the German Opera, Vienna; and he afterwards was appointed to the conductorship of the San Carlo Theatre in Naples. While in Naples, he produced an opera buffa called *Giocinta ed Ernesto*, and an opera seria, *I Portoghesi in Goa*. Both were too German to suit the Italian taste, but later they were well received at Stuttgart. In Paris, and afterwards (1835) in London, he appeared with great success as a pianist. In 1836 he took up his permanent residence in London, and was, during that year, director of the opera buffa at the Lyceum, where he produced an operetta, composed in Naples, *Un Anno ed un Giorno*. Turning his attention afterwards to English opera, he composed *The Gipsy's Warning* (1838), *The Brides of Venice* (1844), and *The Crusaders* (1846), three works which, translated into German, have been well received in the composer's native country. He conducted the opera in Covent Garden Theatre in 1843 and 1844, and the Norwich Musical Festival in 1845, and thereafter conducted the Monday Popular and numerous other concerts and great musical gatherings in London and in the provinces, besides being a successful pianoforte teacher. In 1850 he conducted at Jenny Lind's concerts in America. In 1860 he produced a cantata, *Undine*, at the Norwich Musical Festival, which was very well received. His *Lily of Killarney*, first given in 1862 at Covent Garden, was his greatest operatic success. He produced a cantata, *Richard Cœur de Lion* (1863); an opera di camera, *The Bride of Song* (1864); and the cantatas *St Cecilia* (1866) and *Graziella* (1882). His oratorio, *St Peter*, written for the Birmingham Musical Festival, 1870, was perhaps his masterpiece; it met with extraordinary success. His first symphony also was received with great favour in 1873. His music possesses abundance of fresh and pleasing melody, and shows the hand of a consummate master, without, however, any very pronounced individuality of style. In his earlier works the score owed something to Rossini, but his later compositions betray more of the influence of his master, Weber. In style and feeling, however, they are singularly English to be the composition of a foreigner. He was knighted in 1871, was a corresponding member of the French Academy, and received decorations from almost every country on the Continent. He died in London, June 5, 1885.

Benedict Biscop, a great churchman of Anglo-Saxon times, was born about 628 of a good Northumbrian family. At first in the service of King Oswy, he assumed the tonsure in the Benedictine monastery of Lerins, after his second journey to Rome. On his return to England from his third journey, he was appointed abbot of St Peter's at Canterbury, but this office he held only for two years. He made yet another pilgrimage to Rome, and soon after his return received from Egrifith of Northumbria, in 674, a grant of land between the Wear and the Tyne. Here he founded a monastery, and endowed it with numerous books which he had collected in his visits to Rome. 'He was,' says William of Malmesbury, 'the first person who introduced in England constructors of stone edifices, as well as makers of glass windows.' In 682

he founded a second monastery at Jarrow. Himself a man of the most lofty character, he did much to advance learning and culture in the church, and to his careful fostering of learning we owe his great pupil Bede. He died 12th January 690.

Benedictine, a liqueur. See LIQUEUR.

Benedictines, the general name of all the monks and nuns following the rule of St Benedict (480-543). He founded his first twelve monasteries at Subiaco, near Rome; thence he passed to Monte Cassino, near Naples, where he wrote his *Rule*, and founded the abbey which is still famous. In his lifetime his disciple, St Placid, spread his order in Sicily; and St Maurus in France. St Gregory the Great was the first (590-604) of the fifty Benedictines who have occupied the papal throne, a list which includes such names as St Leo IV., St Gregory VII., and St Pius VII., and which ends with Gregory XVI., the predecessor of Pius IX. St Augustine, the disciple of Gregory the Great, brought the Benedictine rule to England along with the Christian faith, and became the first of a long list of Benedictine archbishops of Canterbury. The English Benedictine, St Boniface, preached the faith in Germany, and founded there the great abbey of Fulda. Ansgar, the apostle of Denmark; Willibrord, of the Frisians and Dutch; Adalbert, of the Bohemians; and Casimir, of the Poles, were all Benedictines. Bede and Anselm in England; Isidore, Leander, and Ildefonsus in Spain; Peter Damiani in Italy, and Bernard in France, are names which illustrate the hold this order had upon the teaching of the Catholic church. As early as 1354 the order had numbered 24 popes, 200 cardinals, 7000 archbishops, 15,000 bishops, 1560 canonised saints, and 5000 holy persons worthy of canonisation, a number since increased to 40,000. It had possessed 37,000 monasteries, 20 emperors, 10 empresses, 47 kings, 50 queens, and an immense number of royal and noble persons. In the 15th century there were 15,107 Benedictine monasteries. The Reformation left not more than 5000; and at the present day the list would not exceed 800.

The Benedictines have been variously grouped together into 'orders' and 'congregations,' named after some principal abbey in which they may have taken their rise, or after some patron saint or country. The first of these sprang from the abbey of Clugny in 910. From Cîteaux, under the Englishman St Stephen, came the Cistercians (1098). In Italy St Romuald founded the order of Camaldoli (1099); St John Gualbert that of Vallombrosa (1070); St William that of Monte Vergine (1119). The Silvestrines (1231) and Celestines (1274) bear the names of their founders; the Olivetans (1319) that of their first abbey. The congregation of Monte Cassino was formed by the union of several abbeys in Italy in 1415, and still exists, though much shorn of its strength. The great abbey of St Paul's in Rome belongs to it. The principal congregation in Germany was that of Bursfeld, which disappeared with the 18th century; but in 1668 the congregation of Beuron arose in the Prussian empire, and now counts four flourishing abbeys. In the Austrian empire there still exist twenty out of a much larger number of independent abbeys, of which many date back to the 8th and 9th centuries. The principal are Salzburg, Melk, Krems, and Martensberg in Hungary. In 1712 a congregation of Armenian Benedictines established itself at San Lazzaro, near Venice, under the name of their founder Meclitar, and still continues a source of religion and learning for its mother-country. In France the congregation of St Vanne was erected in 1600; along with that of Tiron it was absorbed into that of St Maur in 1627 (see MAURISTS).

The Revolution of 1792 swept all away, but in 1837 D. Gueringer founded the 'French Congregation' at Solesmes, and it now reckons three abbeys. In accordance with a Bull of the Lateran Council (1215), which commanded Benedictines to unite together into congregations, eleven Scottish monasteries which had been founded at different dates in various parts of Germany were erected into one body. The most important were Würzburg, Erfurt, and Vienna. Of these none now exist. The English congregation was founded in 1300 by the union of all the English monasteries then existing. It included, among the 113 numbered by Tanner, all the greater abbeys and cathedrals, and four other abbeys which have since become cathedrals of England. It was despoiled at the Reformation, and its few surviving members took refuge and multiplied abroad, whence they returned at the French Revolution. In Scotland the principal Benedictine monasteries were Iona, Dunfermline, Coltingham, Kelso, Arbroath, Paisley, Melrose, Kilwinning, and Lindores. In the United Kingdom in 1887 there were eight Benedictine monasteries for men, and the same number for women, together with a large number of parish churches served by Benedictines. The abbey of Fort Augustus, the only one in Scotland, was founded 1878, and in it is perpetuated whatever remained of the Scottish abbey at Ratisbon. During the present century the order has spread widely in the United States, where there are eight large abbeys and a number of smaller establishments. The mother abbey of St Vincent's, Pennsylvania, numbers 130 monks. Monasteries have been established also in Australia, one among the aborigines, and in New Zealand; and the suppressed congregation of Valladolid and Montserrat in Spain have begun to re-establish themselves. In 1851 a new congregation was erected under the presidency of the abbey of Subiaco, one of the original foundations of St Benedict, and has widely propagated.

The Rule of St Benedict is a modification of that of the eastern ascetics, St Basil, Cassian, &c. It was the first to introduce *Stability*, or the binding of the monk to a permanent abode in a monastery, and in the practice of monastic life till death. This is the first of the Benedictine's three vows; the second is *Conversion of Manners*—i.e. the striving after perfection of life; and the third, *Obedience according to the Rule*, by the tenor of which the monk is bound to chastity, to the renunciation of private property, to retirement from the world, to the daily and public solemnisation of the divine office, and to a life of frugality and labour under filial obedience to the abbot. Hospitality and the other works of mercy, corporal and spiritual, are strongly inculcated in the rule, and among these, Benedictine monks have always given a high place to the work of education and instruction in worldly and religious learning. Both these still form the principal subjects of their employment. From the days of Charlemagne to the 12th or 13th century, the Benedictine monasteries were almost the only repositories of learning; the literary labours of the Maurists in the 18th century are proverbial, and to this day it would be difficult to find a Benedictine monastery without at least its 'internal' school of philosophy and theology. The modern congregation of Beuron is famous for its school of art.

The Benedictine habit consists of a tunic and Scapular (q.v.), over which is worn a long full gown called a *cowl*, with a *hood* to cover the head. The colour is not specified in the rule, and it is conjectured that the early Benedictine wore white as being the natural colour of undyed wool. For many centuries, however, black has been the prevailing colour, whence the term 'black monk' comes to

mean a Benedictine in general, or one who does not belong to certain congregations which have a special colour—e.g. the Camaldolese, the Cistercians and Olivetans wear white, and the Silvestrines blue. The latter are numerous in Ceylon.

St Benedict's twin-sister Scholastica is supposed to have lived under his rule, and Benedictine nuns have always been as numerous as Benedictine monks. At present the number of their convents probably much exceeds that of the monasteries of men. For the 'Benedictine Editions,' see MAURISTS.

See *Annales Ordinis Sti Benedicti*, and *Acta Sanctorum Ordinis Sti Benedicti*, by Mabillon; *Apostolatus Benedictinorum in Anglia*, Reynier; *Album Benedictinum* (St Vincent's, Pennsylvania, 1880); *The Holy Rule of St Benedict* (Fort Augustus, 1885); *The Monks of the West*, Montalembert.

Benediction (from the Lat. *benedicere*, literally, 'to speak well of'; 'to commend') is a solemn invocation of the Divine blessing upon men or things. The ceremony in its simplest form may be considered almost coeval with the earliest expressions of religious feeling. The Sabbath is said to have been blessed. Jacob blessed his two grandsons. Christ 'took bread and blessed it,' and 'lifting up his hands,' blessed his disciples. In the primitive church the custom gradually developed itself in various liturgical forms. In Protestant churches a form of benediction is used at the close of religious services. In the Roman Church a priestly benediction has been defined as a formula of imperative prayer, which, in addition to the desire which it expresses, transmits a certain grace or virtue to the object over which it is pronounced. Such ecclesiastical benedictions are generally accompanied with the sprinkling of holy water and the use of incense, and universally with the sign of the cross. Prescribed forms may be gathered from the missal, breviary, and pontifical, or may be found collected in the *Benedictionale Romanum*. Certain blessings form part of the liturgical services which only occur at stated seasons, as the blessing of the candles on Candlemas Day, of the ashes on Ash Wednesday, and of the palms, the sacred fire, the incense grains, the paschal candle, font and baptismal water, during Holy Week. Many ancient and curious ceremonies are used at the blessing of altars or of church-bells by the bishop. Other objects for which special blessings are provided in the *Benedictionale* are fields, houses, ships, cattle, noxious animals, articles of food, and even railroads and telegraphs. Water mingled with blessed salt for the devotional use of the faithful in church or at home is as a rule prepared every week. This *aqua benedicta* or holy water in turn conveys a blessing to persons or objects aspersed with it. Priests having special faculties for the purpose may bless crosses and rosaries, which only, when so blessed, impart the papal indulgence to those who use them. So great was the importance attached by Roman Catholics to this delegated papal blessing, that in 1571 the English parliament, in retaliation against the pope for attempting to depose Elizabeth, imposed the penalties of præmunire on any one who should bring into the realm an *Agnus Dei* (a medal of wax), crosses, pictures, or beads consecrated or hallowed by the Bishop of Rome, or by authority derived from him. The papal benediction conveyed to a dying person carries with it a plenary indulgence. On certain occasions (as on his jubilee, January 1, 1888), the pope pronounced a solemn benediction *urbi et orbi* (on the city and the world).

BENEDICTION is also the name given in some countries (in French, *Le Salut*) to a brief and popular service of comparatively modern origin in the Roman Church. It consists of certain canticles

and antiphons sung in presence of the sacred host, which is exposed for the occasion on a 'throne' above the altar. The service is concluded by the priest, wrapped in a veil, taking the monstrance which contains the host, and therewith making the sign of the cross over the people, and giving to them in silence the benediction of the most holy sacrament.

Benedic'tus, the canticle of Zacharias (Luke, i. 68-79), used in the Roman service of matins-lauds, and thence adopted into the Anglican morning service.

Benedix, JULIUS RODERICK, a German actor, manager, and play-writer, was born at Leipzig in 1811, and died there September 26, 1873. Of his numerous pieces, the best are his comedies, most of which are favourites in Germany, for their humorous, intricate plot, constant change of incident and scene, and natural, but witty, dialogue. His dramatic works fill 27 vols. (1846-74).

Benefice, or BENEFICIUM, was first applied in the Lombard laws and the Constitutions of Charlemagne to the life-interests in land, which were the reward of military service, and afterwards developed into hereditary feudal grants; but is now used in England to denote any kind of church promotion or dignity, but specially a 'benefice with cure of souls,' such as rectories, vicarages, and other parochial cures, as distinguished from bishoprics, deaneries, cathedral preferments, and other ecclesiastical dignities or offices. Some benefices are called *exempt* or *peculiar*, by which is meant that they are not to be under the ordinary control and administration of the bishop; but such exempt or peculiar benefices are nevertheless, so far as relates to pluralities and residence, subject to the archbishop or bishop within whose province or diocese they are locally situated.

There are, in general, four requisites to the enjoyment of a benefice. 1st, Holy orders, or ordination at the hands of a bishop of the established church or other canonical bishop (a Roman Catholic priest may hold a benefice in the Church of England on abjuring the tenets of his church, but he is not ordained again); 2d, Presentation, or the formal gift or grant of the benefice by the lay or ecclesiastical patron; 3d, Institution at the hands of the bishop, by which the cure of souls is committed to the clergyman; and 4th, Induction, which is performed by a mandate from the bishop to the archdeacon to give the clergyman possession of the temporalities. Where the bishop is himself also patron, the presentation and institution are one and the same act, and called the *collation* to the benefice. The spiritual duties of a benefice are those connected with public worship, baptism, marriage, burial, and the administration of the Lord's Supper, with less defined duties of visitation of and intercourse with parishioners. The emoluments of a rector consist of the freehold of the parsonage house, the glebe, the tithes, and other duties; the vicar has only a proportion of these. The rector is liable for the repair of the chancel, and has serious duties in connection with the church and the churchyard, which in the ordinary case are his freehold. (See Cripps or Phillimore on Church Law.) In Scotland, benefices are divided into temporalities or lands and spiritualities or teinds. The former were taken by the crown at the Reformation and erected into lordships in favour of the lords of erection, titulars, and commendators; but in the 17th century most of these estates returned to the crown. These titulars had also rights of drawing teind from other lands, a public grievance, which was settled by the celebrated decrees arbitral of Charles I. The spiritualities, or main body of the teinds, are still held by

the Church of Scotland (see TEINDS, AUGMENTATION, STIPEND). The election of ministers now proceeds under the Patronage Act, 1874. The minister in Scotland has a manse and glebe, but not the same rights in the church or churchyard, as in England. See ADVOWSON, SIMONY, PLURALITY.

Beneficiary is a legal term used in both England and Scotland to denote a person who is in the enjoyment, or is ultimately entitled to the enjoyment, of any interest or estate held in trust by others. The technical term in the law of England is *Cestui que trust* (q.v.). Thus, annuitants, special legatees, and residuary legatees are all beneficiaries. In charitable trusts of a discretionary character there is often doubt as to who the beneficiaries really are, and both under statute and at common law the courts or the commissioners are occasionally asked to reform a charity, which often means changing the class of beneficiaries. Beneficiaries are entitled to protect the trust estate by interdict and injunction against improper acts of the trustees, and also to sue the trustees for an accounting. See TRUST.

Benefit of Clergy. This expression relates to a former state of the law of England, which shows the power of the clergy and the ignorance of the people. The benefit or privilege meant little short of the total exemption of the clerical order, in respect of crimes and offences, from the jurisdiction and authority of the secular magistrate. The only exception to this was the priest being held in custody by the king himself; but even in that case, he could only remain in such regal custody with the pleasure and consent of the bishop, who had entire control over his person, and over the inquiry into his offence. If a priest or 'clerk' happened to be imprisoned by the secular arm, on a criminal charge or capital felony, he was, on the bishop's demand, to be instantly delivered up without any further inquisition; not, indeed, to be let loose upon the country, but to be detained by the ordinary, till he had either purged himself from the offence, or, having failed to do so, had been degraded. The compurgation before the church court was arranged entirely in favour of the accused. This state of things continued till the Statute of Westminster the First (1275), which provided that the prisoner must first be indicted before he could be claimed, and then in the reign of Henry VI. it was settled that the prisoner must first be convicted, and might either then claim his clergy by plea declining the jurisdiction, or, as was most usually practised, after conviction, by way of arresting judgment. The test of admission to this singular privilege was the clerical dress and tonsure—i.e. the claimant must be strictly in orders and not a mere assistant. The statute *Pro Clero* (1350), however, extended it to all manner of clerks, and by later practice it was extended to all who could read, whether of the clergy or laity—a mark of great learning in those days—and therefore capable of becoming clerks. Women, however, except professed nuns, were until the Reformation excluded. But laymen could only claim it *once*, and upon so doing were burned on the hand, and discharged; to be again tried, however, by the bishop, whose investigation usually resulted in an acquittal, which, although the offender had been previously convicted by a jury, or perhaps on his own confession, had the effect of restoring him to his liberty, his credit, and his property. The mode in which the test of reading was applied was as follows: On conviction, the felon demanded his clergy, whereupon a book (commonly a psalter) was put into his hand, which he was required to read, when the judge demanded of the bishop's commissary, who was present, *Legit ut clericus?*

and upon the answer to this question depended the convict's fate: if it were simply *legit*, the prisoner was burned on the hand, and discharged; but if *non legit*, he suffered the punishment due to his offence. By a series of statutes most of the serious crimes and all capital crimes had been excluded from benefit of clergy before the end of the 17th century, but it was extended to all persons convicted of clergyable offences, whether they could read or not; and instead of burning on the hand, a discretionary power was given to the judge to inflict a pecuniary fine or imprisonment. Newly-created felonies, which were numerous in the 18th century, were not entitled to the benefit. But all further attempts to modify and improve the law on this subject proving impracticable, the benefit of clergy was at last totally abolished, by the 7 and 8 Geo. IV. chap. 28; and now by the 4 and 6 Vict. chap. 22, the same is the law with regard to the peers. This privilege had never any existence or legal meaning in Scotland. See Hale's *Pleas of the Crown*; and Stephen's *History of the Criminal Law of England*, i. 459.

Benefit of Inventory. in the Scots law, was a legal privilege whereby an heir secured himself against unlimited liability for his ancestor, by giving up, within the *Annus deliberandi* (q.v.), an inventory of his heritage or real estate, to the extent of which, and no further, was the heir liable. The method of obtaining this privilege was simplified in 1847 and 1868, but it is now superseded by the general declaration in the Conveyancing (Scotland) Act, 1874, that 'an heir shall not be liable for the debts of his ancestor beyond the value of the estate of such ancestor to which he succeeds.' Of course this does not prevent universal liability where the estate is conveyed by a general settlement of all property belonging to the ancestor. See ANNUS DELIBERANDI, INHERITANCE, DEBT, and MORTGAGE.

Benefit Societies. associations for mutual benefit chiefly among the labouring classes, are better known under the name of FRIENDLY SOCIETIES, and are described under that head; while the associations sometimes called Benefit Building Societies, are discussed at BUILDING SOCIETIES.

Bencke. FRIEDRICH EDUARD, professor of philosophy in Berlin, was born in that city in 1798, and studied theology and philosophy, first at Halle, and then at Berlin. In 1820 he commenced lecturing in the latter university, but his lectures were soon interdicted by the minister Altenstein, as his philosophical views were quite opposed to those of Hegel. For three years he taught at Göttingen, but in 1827 his lectures at Berlin were again allowed, and in 1832, on Hegel's death, he was appointed extraordinary professor of Philosophy. In March 1854 Beneke disappeared suddenly from his residence, and nothing more was heard of him until June 1856, when his body was found in the canal at Charlottenburg. Beneke has more affinity with British thinkers than any other German philosopher. His most important works are on psychology, which he insists must be founded on the facts of our consciousness. His system of psychology is therefore what the Germans call 'empirical,' and his method is the Baconian as pursued in natural science.

Benevento (ancient *Beneventum*), a city of Southern Italy, capital of a Campanian province of the same name, is situated on a hill near the confluence of the Calore and Sabato, 61 miles N.E. of Naples by rail. It occupies the site of the ancient city, out of the materials of which it is entirely built, and is surrounded by walls about 2 miles in circumference. It has a citadel, a fine

old cathedral, some noteworthy churches, and a magnificent arch, erected in 114 A.D. to the honour of the Emperor Trajan, which, with the single exception of that of Ancona, is the best preserved specimen of Roman architecture in Italy. It is an archiepiscopal see, and has a population of (1891) 26,000, chiefly engaged in the manufacture of leather, parchment, and plated goods. The town was in the possession of the Samnites when history first takes notice of it, and it appears to have been captured from them by the Romans some time during the third Samnite war (298-290 B.C.). It was certainly in the hands of the Romans in 274 B.C.; and six years later they changed its name from Maleventum to Beneventum, and made it a Roman colony. The Carthaginians under Hanno were twice decisively defeated in the immediate neighbourhood during the second Punic war. It rapidly rose to be a place of importance under the Roman empire; under the Lombards, who conquered it in the 6th century, it continued to flourish; and at length it became capital of a duchy which included nearly the half of the late kingdom of Naples. This was seized by the Normans; the town was given (1053) to the pope by the Emperor Henry III. Thenceforward, until 1860, when it was united with the kingdom of Italy, Benevento continued, with slight intervals, to be governed through a resident cardinal with the title of Legate. In 1806 it was bestowed by Napoleon, with the title of prince, on Talleyrand; but it was restored to the pope in 1815.—The province of Benevento has an area of 834 sq. m.; pop. (estimated 1892) 245,834.

Benevolence. in the history of the law of England, was a species of forced loan or contribution, levied by kings without legal authority. It was first so called in 1473, when asked from his subjects by Edward IV. as a mark of good-will towards his rule, but similar compulsory 'free-will offerings' had not been uncommon in former reigns. Under Richard III., in 1484, an act of parliament abolished benevolences as 'new and unlawful inventions,' but spite of this they continued to be exacted by Richard himself and by Henry VII. In 1614 James I. tried, but with little success, to raise money by this expedient, and it was never again attempted by the crown; Charles I. expressly declining to have recourse to it.

Benfey. THEODOR, a great orientalist and comparative philologist, was born of Jewish parents near Göttingen in January 1809. He studied in Göttingen, Munich, Frankfurt, and Heidelberg, devoting himself especially to classical and comparative philology. In 1862 he was appointed to the chair of Sanskrit and Comparative Philology in the university of Göttingen, which he held till his death in June 1881. One of his earliest literary efforts was a translation of Terence (Stutt. 1837); after this, however, he turned his attention almost exclusively to comparative philology, oriental languages, especially Sanskrit, and mythology. In his fifty years devoted with rare enthusiasm and persistency to linguistic studies, he did more than any other scholar to enlarge the boundaries of Sanskrit philology. In comparative philology, though an adherent of Bopp, he deviated from his master in deriving all Indo-European words from *monosyllabic primitive verbs*. This conception depends on his theory of the origin of stem suffixes. These, he holds, are almost all derived from a fundamental form *ant*, which appears in the present participle of verbs. To support this view he assumes the most violent permutations of sounds which set all phonetic laws at defiance. For his theory, see his *Lexicon of Greek Roots* (Berl. 1839), *Short Sanskrit Grammar*

(Lond. 1868), and numerous essays. In Sanskrit he laid a foundation for the true study of the Veda by editing the *Sāma Veda* (Leip. 1848) with glossary and translation; and this work he continued by a scholarly translation of the first *mandala* of the Rig Veda in his magazine *Orient und Occident* (Gött. 1863-64). His Vedic grammar, for which he had been collecting materials for many years, was left unfinished. He also published a *Complete Sanskrit Grammar, Chrestomathy and Glossary* (Leip. 1854), and a *Sanskrit-English Dictionary* (Lond. 1866).

In comparative folklore his principal work is a translation of the *Panchatantra* (q.v.), published at Leipzig in two volumes in 1859. It is accompanied with elaborate notes, and the first volume consists entirely of an introduction in which he traces the course of these Indian stories in their wanderings and transformations, both in eastern and western literatures.

Bengal (old *Bangalā*; the *Banga* of Sanskrit topography), a name given to part of British India, but variously signifying—(1) the old historical presidency which, in pre-mutiny times, comprised the greater portion of Northern India; (2) the modern military division, corresponding in extent to the old presidency; and (3) the modern province, sometimes also called Lower Bengal, comprising Bengal Proper, Behar, Orissa, and Chhota Nagpur. The word 'presidency' (a relic of the East India Company's time, when the three settlements were each administered by a president and council) is still loosely applied to the province as well as to Calcutta itself; but it is actually retained in the *Army List*, the Bengal Presidency command being held by the 'Commander-in-chief in India,' to whom the Commanders-in-chief of Bombay and Madras are subordinate. Lower Bengal is so called in contradistinction to the 'Upper Provinces' of the obsolete presidency, which are now placed under separate administrations.

The modern province, ruled by a lieutenant-governor, is the largest and most populous of the twelve divisions of British India. It is nearly as large as Spain, and half as large again as Great Britain and Ireland; while it has a population nearly double that of the United Kingdom. The census of 1881 gave a population of 66,750,520 in British territory (corresponding to a density of 436 per square mile) and 2,845,405 in the feudatory states. The following are the census figures for 1891:

	Square Miles.	Inhabitants.
Bengal Proper.....	70,430	38,277,339
Behar.....	44,139	24,393,504
Chhota Nagpur.....	26,966	4,628,792
Orissa.....	9,053	4,047,352
	150,588	71,346,987
Feudatory States.....	36,634	3,296,379
Total.....	187,222	74,643,366

Roughly speaking, Bengal comprises the low-lying deltas of the Ganges and Brahmaputra, and the alluvial plains stretching along their lower courses. In the N. it is hemmed in by the Himalayan ramparts; in the SW. angle the hilly region of Chhota Nagpur forms a continuation of the Central Indian plateau; while on the SE. a coast-line of 550 miles extends round the top of the Bay of Bengal, from Puri, in the south of Orissa, to the point at which Chittagong is terminated by the Lower Burmah frontier. Although for the most part level, Bengal is diversified in various parts by peaks and spurs thrown out from the great mountain-systems. Lying between 19° 18' and 28° 15' N. lat., and 82° and 97° E. long., it is bounded landwards by the native states of Nepaul, Sikkim, and Bhutan, on the N.; by Assam and Upper Burmah on the E.; by the North-west Provinces

and the Central Indian Agency on the W.; and on the S. by Madras. The province is portioned out into nine large administrative tracts called divisions, each under a commissioner, and of these, five—Calcutta (or Presidency), Burdwan, Rajshahi, Dacca, and Chittagong—form what is known as Bengal Proper, a name which is now purely geographical. The other divisions are Patna and Bhagalpur (forming the old province of Behar), Orissa, and Chhota Nagpur. These commissionerships are again divided into 45 districts, each with a magistrate, and among these may be named the densely-peopled metropolitan districts of Hugli (Hooghly), Howrah, and the 24 Parganas; and the rich trading districts of Dacca, Faridpur, and Patna. The average district in Bengal has an area of 3325 sq. m., more than half the size of Yorkshire. The distinctive features of Bengal are its immense network of rivers, the magnificent range of the Himalayas, the luxuriant but fever-haunted Terai at the base of the great mountain-chain, and the trackless forests and jungles of the Sunderbans (Sunderbunds), on the sea-face of the delta—the almost undisputed home of the tiger and rhinoceros. Besides the main streams of the Ganges and Brahmaputra, the chief rivers are the Gogra, Son, Gandak, Kusi, Tista, Hugli (formed by the Bhagirathi and Jalangi), the Damodar, and Rupnarayan; and, in the extreme south, the Mahanadi, or 'Great River' of Orissa. All the rivers are subject to floods, bring down an immense quantity of soil, and thousands of square miles in the delta thus receive a splendid top-dressing every year. The country is so enriched by this system of recuperation as 'to defy the utmost power of over-cropping to exhaust its fertility.' As compared with Northern India, Bengal is remarkable for the absence of large cities. Calcutta, the capital, is one of the largest cities in the world, having a population of 800,000. But the other towns are small, the next largest being Patna, with 180,000 inhabitants. Altogether there are 33 towns with upwards of 20,000 inhabitants, including Dacca, Gaya, Bhagalpur, Darbhanga, Monghyr, Arrah, Cuttack, Murshidabad, Dinapur, Burdwan, Krishnagar, Naihati, and Chittagong. On the Hugli, within 20 miles of Calcutta, stand the small French settlement of Chandernagore, the Portuguese Hugli, the Dutch Chinsura, and the Danish Serampur. All these are now places of diminished importance, but they give to the river Hugli a peculiar historical significance; all but Chandernagore have been ceded to England, the Danish town as late as 1845.

The climate of the plains is similar to that of the Indian seaboard everywhere—hot and humid. But inland in Behar it is much drier, with hot winds in summer; while in ascending the hills, every variety of climate is met with, till the perpetual snow-line is reached. The ordinary range of temperature in the plains is from about 52° F. in the cold season, to 103° in the shade in summer. In good European houses the temperature in the hottest months can be kept down to 95°. The hill-station of Darjiling, at an elevation of 6685 feet, has a mean temperature of 54°. In the eastern districts the average yearly rainfall is over 100 inches, while on the hillsides this is greatly exceeded. Calcutta has only 66, Darjiling 126, and Chera Punji (in Assam) has 527, the largest fall recorded in the world. Bengal is exposed to the heavy sweep of the Monsoon (q.v.), while cyclonic waves and river inundations are frequent, carrying at times terrible havoc far into the low-lying country. In a cyclonic wave on the Orissa coast in September 1885 there perished 5000 souls. At the same time, earthquakes are not infrequent, a severe shock which traversed the province in July 1885 having caused wide-

spread destruction of property. The people are mostly employed in agriculture, and among the chief products are indigo, jute, the opium poppy, oil seeds, many varieties of rice, cinchona, tea, turmeric, pepper, the silk mulberry, cotton, sugar, and innumerable grains, spices, and drugs. Opium is a government monopoly; and cinchona is chiefly grown at the government plantation at Darjiling, although there are also some private plantations yielding perhaps 30,000 lb. of dry bark. The enormous wealth of Bengal lies in its vast production of articles of commerce. From its position in relation to the interior, a vast traffic passes through Bengal, much of the wheat of the North-west, and the jute and tea of Assam, finding an outlet at Calcutta. Thus, exclusive of opium and railway material, Calcutta receives yearly from the interior commercial products to the value of 40 millions sterling, which are mostly re-exported. With a large foreign trade of between £60,000,000 and £80,000,000 a year, about 95 per cent. of which belongs to Calcutta, the value of the direct trade with Great Britain during the last decade averaged, to Great Britain £16,000,000, and from Great Britain £15,000,000, a year. The principal exports are opium, rice, jute, oil-seeds, indigo, cotton, wheat, and hides and skins. A large trade is done in gunny-bags, Calcutta in one year exporting 65,000,000 of them. In addition to 5876 square miles of reserved forests, there are in cultivation over 36 million acres under rice, 12 million acres under wheat and other food grains, and 3½ million acres under oil-seeds; the other principal crops are sugar, indigo, tobacco, cotton, and tea. Great interest attaches to the cultivation of tea, which rapidly came to hold a front rank among Indian industries. There are about 400 tea-gardens in Darjiling district and the Terai, including Jalpaiguri; the Assam produce also passes through the province. Systematic forest conservancy has done much to check indiscriminate destruction of timber, and to increase the government revenue (from the 'reserved forests').

Bengal has considerable mineral wealth. In Bardwan, coal, iron, and copper are worked, but the iron smelting has hardly been a commercial success. There are about 100 collieries (in four or five different coalfields, of which the most important is at Raniganj), many of them worked by steam-power, and the total output is over 1,500,000 tons. The 50 jute and cotton mills around Calcutta are even a more striking indication of industry, employing 50,000 hands. This new cotton manufacture in some measure takes the place of the old native industry in fine cottons and muslins, almost annihilated by the competition of Lancashire. Large quantities of salt are obtained by evaporating sea water (but the bulk of the salt used in Bengal is imported from Cheshire); and the production of saltpetre is very considerable. Lacquer, sugar, ropes and cables, leather, porcelain and stoneware are also amongst the manufactures. There are over 2000 miles of railway (including the Darjiling-Himalayan, one of the most wonderful mountain-railways in the world). There are 6000 miles of telegraph. Several distinct systems of canals provide for conveyance of goods, and irrigate a vast area of land.

Standing far in advance of the rest of India in education, the enlightened classes in Bengal are largely employed in government service. The province has five colleges affiliated to the university of Calcutta; but there are 50 'institutions' catalogued as giving university education; 2500 secondary schools and over 50,000 primary schools. With engineering, normal, industrial, and other schools, there were in all in 1891 nearly 54,000 public educational institutions, with 1,400,000 pupils, besides

13,000 private institutions, with 140,000 pupils. Bengal has also over 4000 private native schools, with 45,000 pupils. See the articles INDIA and books there cited, CALCUTTA, BRAHMO SOMAJ, &c.

The army in the military province of Bengal amounts in all to 130,000, of whom over 45,000 are British troops. Including Eurasians, there are upwards of 40,000 Europeans in the province, of whom nearly 30,000 are in Calcutta and its neighbourhood. Of the Europeans, 11,000 are British-born. In Bengal there are also 800 Armenians, 300 Chinese (shoemakers and carpenters in Calcutta), 150 Parsis, and 1000 Jews.

Within the province there is a great variety of race, language, religion, and degrees of civilisation. A large proportion of the people are descended from the Aryan stock; but no sharp line can be drawn between those called Hindus and those reckoned aborigines or non-Aryan, as many low-caste Hindus are wholly aboriginal in blood. There is within the lieutenant-governorship every degree of civilisation from that of the English educated, sceptical Hindu gentleman, to the primitive hillmen. Although essentially a Hindu province, Bengal has 23 million Moslem inhabitants, mainly belonging to the upper classes, while 2½ millions are semi-savage tribesmen, and 138,000 are returned as Christian converts. Bengalis speaking Bengali (q.v.) number 36½ millions; Hindustani speakers, 25 millions. In Bengal Proper the Santals are the most notable aboriginal stock; in the feudatory states are the Kolarian or Dravidian Gonds, Kols, and Bhuiyas, as well as Indo-Chinese tribes. Of the whole population, the census returns 46,250,000 as 'unemployed,' but this number includes 30,466,000 women, besides male children. Two millions of women work as agricultural labourers, and nearly as many in manufactures. Of men 15,332,500 are landowners or agriculturists; over a million are commercial; 2½ millions industrial; 624,500 are professional; and 15,830,000 unemployed (mainly old men and children).

The history of Bengal is merged in that of India. The Mohammedan conquest dates from 1200. The East India Company made its earliest settlements, purely commercial in character, in the first half of the 17th century. The old settlement was the key-stone of the British empire in India; and in the opinion of General Chesney (*Indian Polity*) it is even yet the one part of India which would be worth retaining were the rest to go. Main facts in the strictly provincial history are the Permanent Settlement of the Land Revenue enacted by Lord Cornwallis in 1793, by which the rights of proprietors were defined and secured in perpetuity; and the Tenancy Act of 1885, a supplement to the older measure, intended to protect the rights of the cultivators. See INDIA.

Bengal. BAY OF, a portion of the Indian Ocean, of the figure of a triangle. Its southern side, drawn from Coromandel to Malacca, so as merely to leave on the right both Ceylon and Sumatra, may be stated at 1200 miles. The bay receives many large rivers—the Ganges and the Brahmaputra on the north, the Irawadi on the east, and on the west the Mahanadi, the Godavery, the Krishna, and the Canvery. On the west coast there is hardly anything worthy of the name of harbour; while on the east there are many good ports—such as Akyab, Gwa, Maulmain, Tavoy River. The islands in the bay are very numerous, and include the Andaman, Nicobar, and Mergui groups. The monsoons prevail over the whole of the north part of the Indian Ocean, of which the Bay of Bengal is a part, and also over the maritime tracts of Bengal itself. See MONSOON.

Bengali Language, one of the seven great Aryan vernaculars of India, spoken mainly in the basin of the Lower Ganges. See INDIA.

Bengal Light, or BLUE LIGHT, is a brilliant signal-light used at sea in a case of shipwreck, and in ordinary pyrotechny for illuminating a district of country. It is prepared from nitre, sulphur, and the black sulphide of antimony. The materials are reduced to fine powder, thoroughly dried, and intimately mixed in the following proportions by weight: nitre, 6; sulphur, 2; black sulphide of antimony, 1. The mixture constitutes the Bengal light, and when kindled, immediately bursts into rapid and vivid combustion, evolving a brilliant, penetrating, but mellow light. As the fumes evolved during the combustion of the Bengal light contain an oxide of antimony, and are poisonous, the light cannot be used with safety in rooms or inclosed spaces.

Bengazi, a seaport town of North Africa, capital of the Turkish vilayet of Barca, finely situated on the east coast of the Gulf of Sidra. Pop. about 7000 (including some 2000 Levantines and 2500 Jews), who carry on a trade with Mediterranean ports in oxen, sheep, wool, sponges, ostrich feathers, and corn, receiving in return, hides, oil, soap, tobacco, &c.; but of the total imports (£115,000 a year), more than a third is made up of English cotton and woollen goods, coal and iron. There is a considerable caravan trade with the interior, where the nomad population pays an annual tribute of over £10,000, about a fourth of the entire revenue of the pashalic. About 260 ships yearly enter the harbour; it has a lighthouse, worked by the Constantinople 'Compagnie des Phares,' but is rapidly filling up with sand. The town is comparatively clean and well built, and possesses a fine bazaar, and several mosques and synagogues, and a Catholic church. Bengazi is the site of the ancient city of *Hesperis*, which rose to some importance under Ptolemy III., who called it *Berenice*, after his wife. The ruins lie to the north-east of the present town.

Bengel, JOHANN ALBRECHT, a distinguished German theologian and commentator, born at Winnenden, in Württemberg, June 24, 1687. He studied at Tübingen, where, in 1708, he became theological tutor; later in life he held several high offices. He died 2d November 1752. He was the first Protestant author who treated the exegesis of the New Testament in a thoroughly critical and judicious style. He did good service also in the rectification of the text of the Bible, and was the first to classify the manuscript authorities for the text of the New Testament into families (Asiatic and African). The short notes in his *Gnomon Novi Testamenti* (1742) are invaluable, and have been translated into various languages. They were made much use of by John Wesley in his *Notes on the New Testament*, which forms one of the standards of Wesleyan Methodism. Indeed, Wesley's work may be regarded as little more than an abridged translation from Bengel. An exposition of the revelation of St John (1740) and a chronological work—the *Ordo Temporum a Principio per Periodos Economicæ Divine Historiæ atque Prophetiæ* (1741)—gained for Bengel, in his time, a great reputation; some regarding him as an inspired prophet, but the majority as a visionary. In these works he calculated, on the basis he supposed to be laid down in the Apocalypse, that the world would endure for the space of 7777½ years, and that the 'breaking loose and the binding of Satan' would take place in the summer of 1836. See the Lives of him by Burk (2 vols. 1831-37) and Wächter (1865), and Reiff's *Bengel und seine Schule* (1882).

Benguéla (also *Benguella*), a country of Western Africa, bordering on the Atlantic, between Angola on the N. and Mossamedes on the S., and the eastern limits of which are not very definitely fixed. It is usually represented as lying between 10° and 15° S. lat. and 12° and 17° E. long. Its surface is generally mountainous, rising from the coast-line inland in a series of terraces; several important rivers flow through it in a north-west direction to the Atlantic. These rivers have numerous alluents, and water is everywhere so plentiful that it may be found by digging two feet beneath the surface. Sulphur, copper, and petroleum are found in the mountains, and also gold and silver in small quantities. The description of flora and fauna given for Angola (q.v.), of which Benguela is a part, of course applies equally to this latter district.—SÃO FELIPE DE BENGUELA, the Portuguese capital of the above region, is situated on a level plain near the sea, backed by a line of hills, in 12° 33' S. lat. It is very unhealthy, and has a straggling appearance. The loss of trade has, moreover, given it an air of desolation. It was a great slave-station at one time, exporting annually 20,000 slaves to Brazil and Cuba. The present population numbers about 2000 natives and a garrison of 100 men. The harbour is good, though difficult of entrance, but is seldom visited now. See *From Benguella to Yacca*, by Capello and Ivens (1883).

Beni, a river of South America, in the state of Bolivia, rises in the La Paz Cordillera of the Andes, at a height of almost 12,000 feet, and collects all the streams that rush down from the mountains between 14° and 18° S. lat. Flowing through the department of its own name, it joins the Mamore, after a course of over 1000 miles, to form the Madeira, one of the largest affluents of the Amazon. The current is very strong, and there are numerous rapids, but the river is traversed by the rafts and canoes of india-rubber collectors and bark gatherers.

Benicarló, a poor, dirty, walled town of Spain, in the province of Castellón, 84 miles SW. of Tarragona. Pop. nearly 8000, who manufacture 'full-bodied' wines for export to Bordeaux, where they are used in cooking clarets for the English market. Fiery brandy and carobs are also exported.

Benicia, capital of Solano county, California, and formerly capital of the state, is situated on the Carquinez Strait, which connects the San Pablo and Suisun bays, 30 miles NE. of San Francisco. It has a commodious harbour, and is the seat of the United States arsenal for the Pacific coast. Cement, leather, and flour are manufactured, and the town contains several educational establishments, including St Augustine's Theological School. Pop. 2361.

Beni-Hassan, a village of Upper Egypt, on the east bank of the Nile, remarkable for the catacombs excavated in the low hills that rise in this part of the valley. These chambers are about thirty in number, and are supposed to have been used as sepulchres by the principal inhabitants of Hermopolis, a city that stood on the opposite side of the river. Some measure 60 by 40 feet, and pillars, left smooth for hieroglyphics, are cut out of the rock in imitation of the columns that support the roofs of buildings. The sides of the caverns are covered with paintings representing the customs of the ancient Egyptians; and these, although not so artistic as those in the Theban catacombs, are of earlier date, and throw much light on the manners and customs of the people.

Beni-Israel ('sons of Israel'), a remarkable settlement, evidently of Jewish origin, existing in the west of India, chiefly in Bombay and some coast towns. Its adherents abstain from unclean fish

or flesh, keep the great feasts, and have always strictly observed the Sabbath, while they have a distinctly Jewish cast of countenance. Their number is about 5000, mostly artisans, though some are soldiers. They claim to have existed for about a thousand years, and assert that they assumed the name by which they are known because that of Jehudim ('Jews') was hateful to the Mussulmans. Some of them know Hebrew, but Marathi is their ordinary language, and in it they possess some literature. They rarely intermarry with the ordinary Jews. Among them there exists a class, called Kala Israel ('Black Israel'), with which they never intermarry, as the latter are socially much inferior, being either their own descendants by heathen wives, or the offspring of proselytes. A similar distinction exists among the Jews of Cochin. In Bombay an official called *Nassi*, or head, dispenses justice among the Beni-Israel, while the principal authorities in religious matters are the *kajees*; but in the outlying villages these dispose of both ecclesiastical and civil business, with the aid of a council. It should be remembered that the Afghans call themselves Bani-Israel, and claim descent from King Saul.

Benin', a country of Western Africa, lying between the lower Niger and Dahomey. Benin was formerly one of the most powerful kingdoms in West Africa, but now it is broken up into several states of small importance, whilst all the coast-line is British, included either in the colony of Lagos, or in the Niger protectorate, which are separated by the Benin River. The soil is very fertile, producing rice, yams, palms, pepper, plantains, cotton, sugar, &c. The population is dense. The government, customs, and superstitions of Benin are like those of Ashanti. The capital, Benin, is 73 miles inland from the mouth of the Benin River, and has a population of above 15,000. Gato, a harbour lower down the river, is an important centre for the palm-oil trade. Wari or Jakn, 130 miles SE. of Benin, is on an island surrounded by a branch of the Niger. The river Benin is 2 miles wide at its mouth, but has a troublesome bar of mud. Benin was discovered by the Portuguese Alfonso de Aveiro (1486), when a large trade in slaves was carried on. The French Bight of Benin settlements (Porto Novo, Cotonou, Grand Popo, and Agoué) are on the coast of Dahomey.

Benin, BIGHT OF, that portion of the Gulf of Guinea (q.v.) extending from Cape Formosa on the E. to Cape St Paul on the W., a distance of about 390 miles, with a coast-line of 460 miles. Several rivers empty themselves into the Bight of Benin, three of which are accessible to shipping. Palm-oil and ivory are the principal articles of trade at the towns on the coast.

Beni-Sonef', a town of Central Egypt, capital of a province of the same name, on the right bank of the Nile, about 70 miles SSW. of Cairo. A branch line of railway has been constructed westward to Medinet el Fayum, and the town is the entrepôt of all the produce of the fertile valley of Fayum, and has cotton-mills and alabaster quarries. The population of the province (470 sq. m.) is about 250,000; pop. of the town, 11,500.

Benitier, the vase or vessel for Holy Water (q.v.) in Roman Catholic churches, known in England as the holy-water font, vat, pot, stone, stock, or stoup. Benitiers are either movable or fixed; portable ones, commonly of silver, being used in processions; and fixed benitiers placed near the doors of churches, so that the people may dip their fingers in the water, and cross themselves with it as they enter or leave the church.

Benjamin ('son of the right hand'), the youngest and most beloved of the sons of Jacob.

His mother, Rachel, died at his birth, naming the child with her last breath *Benoni* ('son of my pain'), but his father changed this ill-omened name to Benjamin. He was the eponymous founder of one of the twelve tribes of Israel. Its warriors were noted for their skill in archery, and for their cleverness in the use of the left hand. According to the Scripture numeration, the tribe in the desert numbered 35,400 warriors above twenty years of age; and on the entrance into Canaan, 45,600. Its territory, which was small but fertile, lay on the west side of the Jordan, between the tribes of Ephraim and Judah. The chief places were Jericho, Bethel, Gibeon, Gilgal, and Jerusalem, the last of which was on the confines of Judah. In the time of 'the Judges,' the tribe of Benjamin became involved in a war of extermination with the eleven other tribes of Israel, who put to death all the males save 600, who afterwards procured themselves wives by a kind of Sabine rape. Saul, the first king of Israel, was of the tribe of Benjamin, which remained loyal to his son, Ishbosheth. After the death of Solomon, Benjamin along with Judah formed the kingdom of Judah; and on the return from the captivity, these two constituted the principal element of the new Jewish nation. The apostle Paul was a Benjamite.

Benjamin of TUDELA, a Jewish rabbi, was born in Navarre, Spain. He was the first European traveller who gave information respecting the distant East. Partly with commercial views, and partly to inquire into the condition of his dispersed co-religionists, he made a journey, in the years 1159-73, from Saragossa, through Italy and Greece, to Palestine, Persia, and the borders of China, returning by way of Egypt and Sicily. He died in 1173, the last year of his travels. His itinerary—originally written in Hebrew, and frequently republished in Latin, English, Dutch, and French translations—is occasionally concise and valuable; but on the whole must be accepted with qualifications. Like all the early travellers, Benjamin had a greedy ear for the marvellous. His blunders, too, are numerous. The best edition, by Asher (Lond. 1840), contains the original text, with an English translation and learned annotations.

Benjamin, JUDAH PHILIP, Q.C., born in 1811 at St Croix, West Indies, was the son of Anglo-Jewish parents, who emigrated to the United States, where he practised as a lawyer in New Orleans. He early engaged prominently in politics, serving first with the Whigs, and afterwards with the Democrats. He sat in the United States senate from 1852 till Louisiana's secession in 1860, and in February 1861 joined Jefferson Davis's cabinet as Attorney-general. He was for a few months Secretary of War, and then acted as Secretary of State until Davis's capture in 1865, when he escaped with some difficulty to England. He was called to the English bar in the following year, became a Q.C. in 1872, and retired from a large practice in 1881. He died in Paris, 6th May 1884. His *Treatise on the Law of Sale of Personal Property* reached a third edition in 1883.

Benjamin Tree. See BENZOIN.

Ben Lawers, a Perthshire mountain, flanking the NW. shore of Loch Tay. Easy of ascent, it is rich in alpine plants, and there is a magnificent view from its summit, which is 3984 feet high, or with the cairn at the top (rebuilt in 1878), 4004.

Ben Led'i, a mountain (2875 feet) of Perthshire, $4\frac{1}{2}$ miles W. by N. of Callander. A jubilee cairn was erected on it in 1887.

Ben Lo'mond, a Scottish mountain in the NW. of Stirlingshire, on the east side of Loch

Lomond, 18½ miles N. of Dumbarton. It is 3192 feet high, and consists of mica slate, with veins of quartz, greenstone, and felspar porphyry. The summit is precipitous on the north side, with a gentle declivity on the south-east; it is covered with vegetation to the top. Seen from Loch Lomond, it appears a truncated cone, and from between Stirling and Aberfoyle, a regular pyramid. The magnificent view from the top, in clear weather, includes the whole length of Loch Lomond, with its diversified isles, and wooded and cultivated shores, the rich plains of Stirlingshire and the Lothians, the windings of the Forth, the castles of Stirling and Edinburgh, the heights of Lanarkshire, the vales of Renfrewshire and Ayrshire, the Firth of Clyde, the Isles of Arran and Bute, the Irish coast, Kintyre, and the Atlantic. The north semicircle of the horizon is bounded by Bens Lawers, Voirlach, Ledi, Cruachan, and Nevis; while some of the beautiful Perthshire lochs are seen.

Ben Maedhu'i, a mountain (4296 feet) of South-west Aberdeenshire, 18 miles WNW. of Castletown-of-Braemar. One of the Cairngorms, it is not a conspicuous summit, but was formerly thought to be higher than Ben Nevis.

Bennet. See ARLINGTON.

Bennett, JAMES GORDON, founder and proprietor of the *New York Herald*, a native of Scotland, was born at Newmill, Keith, September 1, 1795. Trained for the Roman Catholic priesthood, he emigrated to America in 1819, where he became in turn teacher, proof-reader, journalist, and lecturer. He had acted as casual reporter and writer in connection with several journals, and had failed in one or two journalistic ventures, previous to the issue of the first number of the *New York Herald*, as an independent newspaper, May 6, 1835, price one cent. He spared no effort and expense in securing news, and laid the foundation of its after enormous success. It was the first newspaper to publish the stock lists and a daily money article. At his death, on June 1, 1872, the *Herald* profits were estimated at from £100,000 to £150,000 per annum.—His son, JAMES GORDON BENNETT, has shown like enterprise in the conduct of the *Herald*. H. M. Stanley (q.v.) was sent by him in 1870 on the mission which resulted in the finding of Livingstone; and in conjunction with the *Daily Telegraph*, he supplied the funds for the same explorer's extraordinary journey across Africa by way of the Congo (1874-78).

Bennett, JOHN HUGHES, an eminent physician, born in London, August 31, 1812, graduated at Edinburgh in 1837, and after four years' study in Paris and Germany, settled in Edinburgh as an extra-mural lecturer. A work published in 1841, in which he recommended cod-liver oil in all consumptive diseases, first brought him into notice, and in 1848 he was made professor of the Institutes of Medicine in Edinburgh University—a post which he held until 1874. His health gave way in 1871, and most of his last years were spent abroad. He died at Norwich, September 25, 1875. His original investigations are embodied in numerous treatises and articles in medical journals, and in his *Text-book of Physiology* (Edin. 1870-71).

Bennett, WILLIAM, born in 1804, graduated B.A. at Oxford in 1837, and, taking orders, was incumbent of Portman Chapel, and of St Paul's, Knightsbridge. The latter charge he resigned in 1851, in consequence of an anti-Tractarian outcry; but he was almost immediately presented to the vicarage of Frome in Somersetshire. An extreme High Churchman, he was author of many theological works, but is chiefly remembered through the case of *Sheppard v. Bennett* (1870-72), wherein his teaching on the Real Presence was pronounced to

be not inconsistent with the doctrine of the Church of England. He died 15th August 1886.

Bennett, SIR WILLIAM STERNDALÉ, Mus.D., D.C.L., English pianist and composer, was born at Sheffield, April 13, 1816. After studying for ten years at the Royal Academy, London, he was sent to complete his musical education at Leipzig. He attracted the notice of Mendelssohn at the Düsseldorf Musical Festival, appeared with success at Leipzig in the winter of 1837-38, and was received with great applause when he returned to London. In 1838 he was elected member of the Royal Society of Music, and in 1856 became professor of Music at Cambridge. At the opening of the International Exhibition, 1862, Tennyson's ode, *Uplift a Thousand Voices*, was sung to music by Bennett. In 1868 he became principal of the Royal Academy of Music; and was knighted in 1871. He died February 1, 1875, and was buried in Westminster Abbey. His published compositions include a symphony, four concert overtures, the two cantatas *The May Queen* and *The Woman of Samaria*, and a few songs. But his peculiar individuality is best exemplified in his works for the pianoforte, of whose capabilities he was a great master; of these, the principal are four concertos and a capriccio with orchestra, two sonatas, and numerous studies. His music is characterised by graceful fancy and delicate finish in the minutest details, rather than commanding power or depth of feeling. His earlier works resemble Mendelssohn's, but a better parallel for the genius of his music generally has been pointed out in Scarlatti, his favourite master in pianoforte music. In his later years his creative activity was almost sunk in that of the teacher. Since his cordial recognition by Mendelssohn and Schumann, he has remained till lately almost the sole representative of English music at all widely known on the Continent.

Ben Nevis, a mountain of Inverness-shire, 7 miles SE. of Fort William, by a new carriage-road opened in 1880. The loftiest summit in Great Britain, it has a height of 4406 feet, with a tremendous precipice of 1500 feet on the north-east side. Granite and gneiss form the base of the mountain, which above is composed of porphyry. Till a road to the top was made in 1883, the mountain was difficult of ascent. A meteorological observatory was erected on the summit in 1883, and daily observations have since been made and communicated by telegraph wire to the world. There is now beside it a shelter for travellers.

Bennigsen, LEVIN AUGUST THEOPHIL, COUNT, a general in the Russian service, was born at Brunswick in 1745, and having entered the Russian army in 1773, soon attracted the notice of the Empress Catherine, who employed him to carry out her designs against Poland. He fought at Pultusk (1806), and held the chief command in the murderous struggle at Eylau (1807). When Napoleon invaded Russia in 1812, Bennigsen commanded the Russian centre on the bloody field of Borodino. Before the French began their retreat, he gained a brilliant victory over Murat at Tarutino (October 18). Differences with Kutusov made him retire for a time from the service; but after that general's death, he took the command of the Russian army of reserve, fought victoriously at the battle of Leipzig, and was created count by the Emperor Alexander on the field. Failing health made him retire finally, in 1818, to his paternal estate in Hanover, where he died in 1826.

Ben-Rhydding, a hydropathic establishment in the West Riding of Yorkshire, in a beautiful situation on the right bank of the river Wharfe, 15 miles NW. of Leeds. The building, erected in 1846 at the cost of nearly £30,000, is a very

imposing pile, on an eminence half-way up the side of the valley. There is accommodation for a large number of patients and visitors, and extensive pleasure-grounds around. In addition to the usual appliances of the water-cure, and a variety of gymnastic exercises, Dr McLeod (who died in 1875) introduced the compressed-air bath. The name Ben-Rhydding is a modern coinage.

Benshie. See BANSHEE.

Benson. EDWARD WHITE, Archbishop of Canterbury, born near Birmingham in 1829, graduated at Cambridge in 1852 as a first-class and senior optime, and was for some time a master at Rugby. He held the head-mastership of Wellington College from its opening in 1858 to 1872, when he was made a canon and chancellor of Lincoln Cathedral. In 1875 he was appointed chaplain-in-ordinary to the Queen, and in December 1876 was nominated to the newly-erected bishopric of Truro. Here he began the building of a cathedral (1880-87), most of the first cost, £110,000, having been gathered by his own energy. In 1882 he was translated to Canterbury to succeed Dr Tait as primate of all England. A high churchman, Dr Benson was frequently select preacher at both universities, and published several volumes of sermons, a small work on Cathedrals, and a valuable article on St Cyprian. A distinguished ecclesiastical lawyer and diplomatist, he gave the important judgment in the Lincoln case on ritual. He died suddenly at Hawarden, October 11, 1896. See his work, *Cyprian: His Life, His Times, His Works* (1897), and *Life* by his son, A. C. Benson (1899). His third son, Edward Frederic (b. 1867), is author of *Dodo* (1893), *The Rubicon* (1894), and other works.

Bent Grass (*Agrostis*), a genus containing about sixty species (see GRASSES, PASTURE).—Common Bent Grass (*A. vulgaris*), abounding on dry elevated lands, becomes a pest in arable land. *A. canina* is also common.—Marsh Bent Grass (*A. alba*) is found in moist situations, and a variety (*A. stolonifera*) is known as Florin Grass. *A. dispar*, American Herd Grass, or Red Top Grass, is cultivated in France. The rarer and more delicate *A. spica-venti* is chiefly admired for its graceful appearance. Most of the European species are North American also. In the United States and Canada some of the bents are highly important as pasture and forage plants. On suitable soils *A. vulgaris* and *alba* give excellent crops of hay.

Bentham. GEORGE, botanist, nephew of the jurist, was born in 1800 at Stoke, a village since absorbed in Portsmouth. The son of an officer who had risen to high rank in both the Russian and English services, young Bentham's earlier years were spent largely abroad, but from 1826 to 1832 he lived with his uncle, to whom he acted as secretary while carrying on his own legal studies. His *Outlines of a New System of Logic* (1827) is a remarkable book; herein for the first time is clearly set forth the doctrine of the quantification of the predicate, in which he thus anticipated Sir William Hamilton. Only sixty copies, however, were sold when the publishers became bankrupt; and the fact that the work contained this discovery was not recognised until 1850, although Bentham's claims have been fully vindicated since. Though called to the bar, he soon abandoned the law for botany. He had catalogued the plants of the Pyrenees (1824-26), and had been elected in 1828 a Fellow of the Linnean Society, and in 1829 secretary of the Horticultural Society. He now devoted himself to his new study, and soon published his important *Labiatarum Genera et Species* (1832-36). In 1854 he presented his collections to the Royal Gardens at Kew, where for the rest of

his life he was engaged almost every day in his task of systematisation and description. He there elaborated the flora of Hong-Kong and of Australia, and in conjunction with Sir Joseph Hooker, completed his exhaustive and valuable *Genera Plantarum* (3 vols. 1862-83), which may be said to summarise our present knowledge of botany. His numerous other writings have done much to elucidate the flora of almost every region outside the Arctic circle. He died 10th September 1884. From 1863 to 1874 president of the Linnean Society, Bentham was a member of many other British and foreign learned bodies, and in 1878, on the completion of the Australian flora, received a Companionship of St Michael and St George. See an article in *Nature*, October 2, 1884.

Bentham. JEREMY, writer on jurisprudence and ethics, was the son of a pushing attorney in London, where he was born (in Red Lion Street, Houndsditch) on 15th February 1748. At the age of seven he was sent to Westminster School; and in 1760, being only twelve years old, he entered Queen's College, Oxford, where he took his B.A. degree in 1763. But though his years were so tender, he appears to have been less unprepared than might be supposed to benefit by the university; for before entering it, he had already, by his precocious tendency to speculation, acquired the title of 'the philosopher.' His father, who expected him to become Lord Chancellor, set him to study law at Lincoln's Inn, where he was called to the bar in 1772. He never practised, however, having a strong distaste for his profession, which is paraded in many of his writings. Turning from the practice of law to its theory, he became the greatest critic of legislation and government in his day. His first publication, *A Fragment on Government* (1776), was an acutely hypercritical examination of a passage in Blackstone's *Commentaries*, prompted, as he has himself explained, by 'a passion for improvement in those shapes in which the lot of mankind is meliorated by it.' The *Fragment* abounds in fine, original, and just observation: it contains the germs of most of his after writings, and must be highly esteemed, if we look away from its disproportion to its subject and the writer's disregard of method. It procured him, in 1781, the acquaintance of Lord Shelburne (Lansdowne), at whose seat, Bowood, he afterwards passed perhaps the most agreeable hours of his life. Here it was that he met Miss Caroline Fox (Lord Holland's sister), who was still a young lady, when Bentham, in 1805, offered her his heart and hand, and was rejected 'with all respect.'

On the death of his father in 1792, he succeeded to property in London, and to farms in Essex, yielding from £500 to £600 a year. He lived frugally, but with elegance, in Queen Square, Westminster; and employing young men as secretaries, got through an immense amount of work and correspondence. By a life of temperance and great self-complacency, in the society of a few devoted friends ('who,' says Sir James Mackintosh, 'more resembled the hearers of an Athenian philosopher than the proselytes of a modern writer'), he attained the age of eighty-four, dying 6th June 1832. In accordance with his own directions, his body was dissected; and his skeleton, dressed in his accustomed garb, is preserved at University College, London.

A pamphlet on *The Hurd Labour Bill* (1778), recommending an improvement in the mode of criminal punishment, was an excerpt from his *Rationale of Punishments and Rewards* (1825), which was written in 1775, but first saw the light in a French translation by Dumont (1811). In these two works, Bentham did more than any other writer of his time to rationalise the theory

of punishments by consideration of their various kinds and effects, their true objects, and the conditions of their efficiency. He published in 1787 *Defence of Usury*; in 1789, *Introduction to the Principles of Morals and Legislation*; in 1802, *Discourses on Civil and Penal Legislation*; in 1813, *A Treatise on Judicial Evidence*; in 1817, *Paper relative to Codification and Public Instruction*; in 1824, *The Book of Fallacies*. His works were collected and edited in 1843 by Bowring and John Hill Burton, in 11 volumes. It is well, however, for Bentham's reputation, that it does not rest wholly on his published writings; and that he found in Dumont, the Mills, and Sir Samuel Romilly, generous disciples to diffuse his principles and promote his fame. In his early works, his style was clear, free, spirited, and often eloquent; but, from 1810, it became overloaded and darkened with technical terms. It is in regard to these more especially that M. Dumont has most materially served his master by arranging and translating them into French, through the medium of which language Bentham's doctrines were propagated throughout Europe, till they became more popular abroad than at home. James Mill, himself an independent thinker, did much in his writings to extend the application in new directions of Bentham's principles, a work in which, apart from his original efforts, he achieved a lasting monument of his own subtlety and vigour of mind.

In all Bentham's ethical and political writings, the doctrine of utility is the leading and pervading principle; and his favourite vehicle for its expression is the phrase, 'the greatest happiness of the greatest number,' which was first coined by Priestley, but owes its prominence in politics to Bentham. 'In this phrase,' he says, 'I saw delineated for the first time a plain as well as a true standard for whatever is right or wrong, useful, useless, or mischievous, in human conduct, whether in the field of morals or politics.' In the application of the principle Bentham arrived at various conclusions, which he advocated irrespective of the conditions of society in his day, and of the laws of social growth, which, indeed, neither he nor his contemporaries understood. He demanded nothing less than the immediate remodelling of the government, and the codification and reconstruction of the laws; and insisted, among other changes, on universal suffrage, annual parliaments, vote by ballot, and paid representatives. Many of his schemes have been realised, many more are in the course of realisation; the end and object of them all was the general welfare, and his chief error lay in conceiving that organic changes are possible through any other process than that of growth and modification of popular needs, ideas, and institutions. It was this error that led the philosopher, in his closet in London, to devise codes of laws for Russia (through which country he made a tour in 1785) and America, the adoption of which would have been equivalent to revolutions in these countries, and then bitterly to bewail the folly of mankind when his schemes were rejected. But in Mill's words, 'he found the philosophy of law a chaos, and left it a science.' He may be regarded as the philosophic pioneer of Liberalism and Radicalism, and holds a high place in the history of political thought.

See J. H. Burton's *Benthamiana* (1843), Life in Bowring's edition of his works, and the articles JOHN STUART MILL, UTILITARIANISM, &c.

Benthamia, a sub-genus of *Cornaceæ* (q.v.) in which the many small drupes grow together. *Benthamia fragifera*, a native of Nepal, is a small tree, with lanceolate leaves, fragrant flowers, and a reddish fruit, not unlike a mulberry, but larger; not unpleasant to the taste. Its fruit has been known to ripen in the south of England.

Bentinck, WILLIAM, first Earl of Portland, born in Holland in 1649, was the descendant of a noble family which in the 14th century had migrated from the Palatinate to Gelderland, where it is still represented by a younger line. He was from boyhood the favourite and friend of William III., and was founder of the fortune of the Bentinck family in England. He was constantly employed, both in military and diplomatic services, and trusted beyond all others with the secrets of the king's foreign policy. After the coronation of William and Mary, Bentinck was created an English peer, and presented with large estates and numerous offices in the royal household; but these last he resigned in 1699, from jealousy of Arnold van Keppel, Earl of Albemarle. The king's affection, however, never wavered to the end of his life, and his last audible words were an inquiry for his favourite. Bentinck died in 1709.—WILLIAM CAVENDISH BENTINCK, third Duke of Portland, born in 1738, entered Lord Rockingham's cabinet in 1765, and succeeded him as leader of the Whig party. He was twice prime-minister—April to December 1783, and 1807-9; but his best work was done as Home Secretary under Pitt, with charge of Irish affairs, throughout the eventful period 1794-1801. He died a month after resigning the premiership, November 30, 1809.—LORD WILLIAM CAVENDISH BENTINCK, Indian statesman, second son of the third Duke of Portland, was born in 1774, and became an ensign in the Coldstream Guards in 1791. Having served with distinction in Flanders and Italy, he was governor of Madras (1803-7), where he advocated several useful reforms; but his proscription of sepoy heards and turbans led to the massacre of Vellore, and his own immediate recall. From 1808 to 1814 he was serving in the Peninsula and Italy; in 1827 he was appointed governor-general of Bengal, and in 1833 became the first governor-general of India. His policy in India was pacific and popular, and his viceroyship was marked by the suppression of suttee and thuggism, the educating and employment of natives, the opening up of the internal communication, and the establishment of the overland route. He returned to England in 1835, and died at Paris, June 17, 1839. See a Life by Boulger (1892).

LORD GEORGE BENTINCK, sportsman and leader of the Protectionists, the third son of the fourth Duke of Portland, was born 27th February 1802, and, entering the army in 1819, attained six years afterwards the rank of major. From 1822 to 1825 he was private secretary to his uncle, Mr Canning, and in 1826 was elected member for Lynn-Regis. At first, attached to no party, he voted for Catholic emancipation and for the principle of the Reform Bill, but against several of its most important details, and in favour of the celebrated Chandos clause. On the formation of Peel's ministry in December 1834, he and his friend Lord Stanley, afterwards Earl of Derby, with some adherents, formed a separate section in the House of Commons; but, on Peel's resignation in the following April, Lord George openly joined the Conservative party, and in 1841 received from Peel an offer of office, which he declined, being at that time too deeply engrossed in racing and field-sports. When Peel introduced his free-trade measures in 1845, a large body of his supporters formed a Protection party, Lord George assuming its leadership, and taking henceforth a prominent part in the debates. A hard hitter, and a master of figures, he was no orator; yet his speeches in the session of 1846 were most damaging to the government of Sir Robert Peel, and contributed in no small degree to hasten its downfall. He was always a champion of religious liberty, advocating the removal of the Jewish disabilities, and the endowment of the Irish Catholic

clergy out of the land; and at the time of the potato famine he wanted government to lend £16,000,000 for reproductive works in Ireland. He was an 'Admirable Crichton' of field-sports, and though he never did win the Derby, had brilliant success on the turf, whose dishonest practices he showed the utmost zeal to suppress. He died suddenly, 21st September 1848, whilst walking near Welbeck Abbey. See his *Life* by Lord Beaconsfield (1851), and his *Racing Life* by Lawley (1892).

Bentley, RICHARD, scholar, was born of yeoman parentage at Oulton, in the West Riding of Yorkshire, January 27, 1662. After four years at Wakefield grammar-school, he entered St John's College, Cambridge, in 1676, as subsizar. Little is known of his university career, except that he showed early a strong taste for the cultivation of ancient learning. At the usual time, he took the degree of Bachelor of Arts; and in 1682 he was appointed by his college to the head-mastership of Spalding grammar-school, in Lincolnshire. Within the year he resigned this situation to become tutor to the son of Dr Stillingfleet, then Dean of St Paul's, and subsequently Bishop of Worcester. In 1689 he accompanied his pupil to Oxford, where he had full scope for the cultivation of classical studies; and that he succeeded in acquiring there some local reputation is evinced by his having been twice appointed to deliver the Boyle Lectures on the Evidences of Natural and Revealed Religion. He had taken orders in 1690, and to Stillingfleet he owed various good ecclesiastical preferments, with the post of librarian of the King's library at St James's. His *Letter to Mill* (1691) on the chronicle John Malalas is itself a masterpiece; but it was the *Dissertation upon the Epistles of Phalaris* (1699), an expansion of an earlier essay, that established his reputation throughout Europe, and may be said to have commenced a new era in scholarship. The principles of historical criticism were then unknown, and their first application to establish that the so-called Epistles of Phalaris (q.v.), which professed to have been written in the 6th century B.C., were the forgery of a period some eight centuries later, filled the learned world with astonishment.

In 1700 Bentley was appointed Master of Trinity College, Cambridge; and in the following year he married Joanna Bernard, the daughter of a Huntingdonshire knight. The history of Bentley's Mastership of Trinity is the narrative of an unbroken series of quarrels and litigations, provoked by his arrogance and rapacity, for which, it must be confessed, he was fully as well known during his lifetime as for his learning. He contrived, nevertheless, in 1717, to get himself appointed regius professor of Divinity, and, by his boldness and perseverance, managed to pass scathless through all his controversies. Notwithstanding that in 1714 one Bishop of Ely, the visitor of Trinity, was hindered only by death from pronouncing sentence depriving him of his mastership, that in 1718 the university senate deprived him of his degrees, and that in 1734 another bishop did actually pronounce his deposition, he was in full possession of both mastership and degrees at the time of his death. This stormy life did not impair his literary activity. He edited various classics—among others, Horace (1711) and Terence (1726)—upon which he bestowed vast labour. Emendations were at once his forte and foible—the latter conspicuously in his edition of *Paradise Lost* (1732). He is, perhaps, more celebrated for what he proposed than for what he actually performed. The proposal (1720) to print an edition of the Greek New Testament, in which the received text should be corrected by a careful comparison with the Vulgate and all the oldest

existing Greek MSS., was then singularly bold, and evoked violent opposition. He failed in carrying out his proposal; but the principles of criticism which he maintained have since been triumphantly established, and have led to important results in other hands, as in Lachmann's. He is to be regarded as the founder of that school of classical criticism of which Porson afterwards exhibited the chief excellences as well as the chief defects; and which, though it was itself prevented by too strict attention to minute verbal detail from ever achieving much, yet diligently collected many of the facts which men of wider views are still grouping together to form the modern science of comparative philology. Bentley died 14th July 1742, leaving behind him one son, Richard, who inherited much of his father's taste with none of his energy, and two daughters, one of whom, Joanna, married, and was the mother of Richard Cumberland the dramatist. See Monk's *Life of Bentley* (2 vols. 1833); Jebb's *Bentley* (1882); and Dyce's unfinished edition of his works (3 vols. 1836-38).

Benton, THOMAS HART, an American statesman, born in North Carolina in 1782, settled in Tennessee, where he studied law, and was elected to the legislature. In 1812 he raised a regiment of volunteers, and also served on General Jackson's staff. After the war, he started a newspaper in St Louis, by which he became involved in several duels. On the admission of Missouri as a state, he was chosen United States senator in 1820, and in this post, during thirty years' continuous service, took a leading part in public affairs. He died in Washington, April 10, 1858. A determined opponent of Calhoun's nullification scheme, he afterwards supported Jackson in his war on the United States bank, and earned the sobriquet of 'Old Bullion' by his opposition to the paper currency. He published *A Thirty Years' View, or a History of the Working of the American Government from 1820 to 1850* (2 vols. 1854-56); and *An Abridgment of the Debates of Congress from 1789 to 1856* (15 vols. 1857).

Bennuë (spelt also *Binnuë* and, by Dr Barth, *Bennurë*), an important river of Central Africa, forming the great eastern affluent of the Niger, which it joins about 230 miles above the mouth of that river in the Gulf of Guinea. Dr Barth describes the Bennuë as being 800 yards across, with a general depth in its channel of 11 feet, and 'a liability to rise under ordinary circumstances at least 30 feet, or even at times 50 feet higher.' In 1854 an expedition under the command of Dr Baikie explored it as far as Dulti, a place about 350 miles above its confluence with the Niger. In a second expedition, undertaken in 1862, Dr Baikie explored as far north as Kano, in Hausa. The Church Missionary Society sent out an exploring party in 1879, under Mr Flegel, who, in 1883, reached its sources, in the Adamawa (q.v.) country, in 7° 30' N. lat. and 13° E. long. Flowing through wide tracts of fertile territory, and navigable for 700 miles, the Bennuë is a highway into the heart of the Soudan, and is evidently destined to be an important channel of commerce with Central Africa.

Benyowsky, MAURICE AUGUSTUS, COUNT DE, a remarkable Hungarian adventurer, born in 1741. While fighting for the Polish Confederation, he was taken prisoner in 1769, and banished to Kamchatka, where he was made tutor in the family of the governor. In this capacity he gained the affections of the daughter of the governor, by whom he was assisted in his plans for escape; which, however, was not effected without a struggle, in which the governor was killed. Benyowsky, with ninety-six companions, set sail in a ship well armed and provisioned, and with a considerable amount of

treasure, and reached France in 1772. Invited by the French government to found a colony at Madagascar, he arrived on the island in February 1774, and was made king in 1776 by the chiefs in conclave, he adopting the native costume. His relations with the French were now not always friendly, and while in contention with the government of Mauritius, he was killed in battle, May 23, 1786. See *Memoirs and Travels of Benyowsky, written by Himself* (1790; new ed. by Pashfield Oliver, 1893).

Benzene, a compound of carbon and hydrogen, C_6H_6 , discovered by Faraday in 1825, in a tarry liquid resulting from the distillation of oil. It must not be confounded with Benzine or Benzoyl, which names have at different times been used for benzene. *Benzine* is the name given to a distillate from American petroleum, which is much used as a substitute for turpentine, and for dissolving oils and fats. *Benzoyl* is the commercial name applied to a mixture of substances, including benzene and its homologues. *Benzol* is synonymous with benzene, while *benzoline* is a name applied to benzene and impure benzene indiscriminately. Benzene is found amongst the products of the destructive distillation of a great many organic bodies. The most abundant source of benzene is coal-tar (see GAS, COAL). On distilling coal-tar, the more volatile liquid hydrocarbons pass over first, mixed with acid and basic compounds, and constitute what is known as light oil or coal naphtha. When the crude naphtha is purified by redistillation and subsequent agitation, first with sulphuric acid, and then with caustic soda, an oil is obtained which consists mainly of benzene and its homologues. By submitting this oil to a process of fractional distillation, a portion is obtained, boiling at 176° – 212° (80° C.– 100° C.), from which benzene crystallises out on cooling the liquid to 32° (0° C.). The benzene is freed by pressure from the substances remaining liquid at this temperature. Commercial benzene is, however, always impure. Pure benzene is most readily obtained by cautiously distilling a mixture of one part benzoic acid with three parts of slaked lime. The mixture of benzene and water which passes over is shaken up with a little potash, the benzene decanted, treated with calcium chloride to take up the water, and the dried benzene thus obtained is rectified on the water-bath. At ordinary temperatures benzene is a thin, limpid, colourless liquid, evolving a characteristic and pleasant odour. At 32° (0° C.) it crystallises in beautiful fern-like forms, which liquefy at 40° (4° – 5° C.); and at 176° (80° C.) it boils, evolving a gas which is very inflammable, burning with a smoky flame. It readily dissolves in alcohol, ether, turpentine, and wood-spirit, but is insoluble in water. It is valuable to the chemist from the great power it possesses of dissolving caoutchouc, gutta-percha, wax, camphor, and fatty substances. Impure benzene is thus much used in removing grease-stains from woollen or silken articles of clothing. When heated, benzene also dissolves sulphur, phosphorus, and iodine. Although commercially of importance, from the chemical point of view benzene is a compound of surpassing interest. It consists of 12 parts of carbon by weight, with 1 part of hydrogen, and might therefore be represented by the formula CH ; but it has been found that the molecule weighs six times as much as this, and requires the formula C_6H_6 . The manner in which the atoms are arranged in the molecule has already been referred to in the article on the AROMATIC SERIES, and it will be seen by a reference to the graphic formula there given, that the number of compounds derivable from benzene is practically unlimited. The so-called coal-tar colours are all derivations of benzene (see DYE-STUFFS, and ANILINE).

Benzerta. See BIZERTA.

Benzoic Acid, or the *Flowers of Benzoïn*, has been known since the beginning of the 17th century, and occurs naturally in many balsamiferous plants, and especially in benzoïn gum, from which it may be readily obtained by several processes. The simplest is as follows: The coarsely-powdered resin is gently heated in a shallow iron pot, the mouth of which is closed by a diaphragm of coarse filter-paper. Over this is tied a covering of thick paper somewhat like a hat. The porous filter-paper allows the vapours of benzoic acid to pass through it, but keeps back the empyreumatic products. At the end of the operation, the hat-like cover is found lined with a crystalline sublimate of benzoic acid which is nearly pure, being mixed only with traces of a volatile oil, which gives it a pleasant smell, like vanilla. The benzoic acid thus prepared is the best for pharmaceutical purposes. Benzoic acid is also prepared from the urine of graminivorous animals. The urine is allowed to putrefy, then mixed with milk of lime and filtered. The filtrate, concentrated by evaporation, gives with hydrochloric acid a precipitate of benzoic acid. Benzoic acid thus prepared is cheaper, but always smells of urine. By subliming it with a small quantity of benzoïn gum, the pleasant vanilla-like smell may, however, be imparted to it also. Benzoic acid is always in the form of snow-white, glistening, feathery crystals, with a fairy aspect of lightness, having a warm, acid, and acidulous taste. It is readily dissolved by alcohol and ether, but sparingly soluble in water, which, however, dissolves it readily on the addition of borax or phosphate of soda. Benzoic acid is one of the materials present in *Tinctura Camphoræ Composita*, and has been administered in chronic bronchial affections, its value being due to its locally stimulating properties. It has also been used largely in genito-urinary diseases. Benzoic acid taken into the stomach increases within three or four hours the quantity of hippuric acid in the urine. It forms a numerous class of compounds with the oxides of the metals, lime, &c., called benzoates. The chemical formula for crystallised benzoic acid is C_6H_5COOH . Oil of bitter almonds (hydride of benzoyl) is the aldehyde of benzoic acid (see ALDEHYDES), and the corresponding alcohol, benzoic or benzylic alcohol, is also known.

Benzoïn, BENJAMIN, or BENZOIC GUM, a fragrant resinous substance, formed by the drying of the milky juice of the Benzoïn or Benjamin Tree (*Styrax*, or *Lithocarpus benzoïn*), a tree of the natural order Styracaceæ, and a congener of that which produces Storax (q.v.), a native of Siam, and of Sumatra and other islands of the Indian Archipelago. Benzoïn is first mentioned by Batuta in 1350 A.D. as Java Frankincense (Arabic *Lubân Jâwî*), corrupted into Banjawi, Benjoïn, Benzoë, &c. Benzoïn comes to us in reddish-yellow transparent pieces. Different varieties, said to depend upon the age of the trees, are of very different price; the whitest, said to be the produce of the youngest trees, being the best. Amygdaloidal benzoïn contains whitish almond-like tears diffused through its substance. Benzoïn is obtained by making longitudinal or oblique incisions in the stem of the tree: the liquid which exudes soon hardens by exposure to the sun and air. Benzoïn contains about 14 to 18 per cent. of Benzoic Acid (q.v.), although in some varieties this is either entirely wanting or replaced by 11 per cent. of cinnamic acid. A very fragrant oil, *styröl*, is present in small proportion (a few drops from a pound), the bulk of the gum consisting of resin. Benzoïn is used in perfumery, in pastilles, and for incense, being very fragrant and aromatic, and

yielding a pleasant odour when burned. Its compound tincture is prepared by macerating benzoïn, along with storax, tolu, and aloes, in rectified spirit for seven days, and subsequent straining, when the Compound Tincture of Benjamin (called variously Wound Balsam, Friar's Balsam, the Commander's Balsam, or Jesuit's Drops) is obtained. It is frequently applied to wounds directly; or is used as an exterior varnish over a bandage. In the preparation of court-plaster, sarcenet (generally coloured black) is brushed over with a solution of isinglass, and then with a coating of the alcoholic solution of benzoïn. The tincture is likewise used in the preparation of soaps and washes. Benzoïn possesses stimulant properties, and was formerly much used in medicine, particularly in chronic pulmonary affections. The name *Asa dulcis* (q.v.) was given to it in the 16th century.—The milky juice of *Terminalia benzoïn*, a tree of the natural order of Combretaceæ, becomes, on drying, a fragrant resinous substance resembling benzoïn, which is used as incense in the churches of the Mauritians. It was at one time erroneously supposed that benzoïn was the produce of *Benzoïn odoriferum*, formerly *Laurus benzoïn*, a deciduous shrub of the natural order Lauraceæ, a native of Virginia, about 10 to 12 feet high, which still bears in America the name of Benzoïn, or Benjamin Tree, and is also called Spicewood or Fever-bush. It has a highly aromatic bark, which is stimulant and tonic, and is much used in North America in intermittent fevers. The berries are also aromatic and stimulant.

Benzoyl, the radical of the benzoic series, represented by the formula C_6H_5O , is a hypothetical substance supposed to exist in benzoic acid and many other bodies. Thus, benzoic acid, from this point of view, is regarded as hydrate of benzoyl, C_6H_5OOH , and the oil of bitter almonds as the hydride of benzoyl, C_6H_5OH . As further examples of this group of bodies, we may mention benzoyl chloride, C_6H_5OCl , and benzoyl cyanide, C_6H_5OCN . *Dibenzoyl* (C_6H_5O)₂, or benzoyl, as it is sometimes called, may be looked on as the above-mentioned radical in the free state, and is prepared by the action of sodium amalgam on benzoyl chloride, in small colourless prisms, soluble in alcohol and ether.

HYDRIDE OF BENZOYL is the volatile or essential oil belonging to the benzoic series. It is represented by the formula C_6H_5OH , and has been already considered under ALMONDS, VOLATILE OIL or ESSENTIAL OIL OF (q.v.).

Beowulf, the name of an Anglo-Saxon poem of epic character, which relates the heroic deeds of Beowulf, prince of the Geatas, especially his struggle with the Grendel, a grisly monster of the fens and moors, as well as its mother; and a long time after with a dragon, which victory cost him his life.

The only manuscript of the poem in existence is an inaccurately written parchment codex now in the British Museum, which once belonged to Sir Robert Cotton, and was much injured by the fire in the Cottonian Library in 1731. The poem consists of 6356 short alliterative lines, and is the oldest large poem in any Teutonic tongue. Its language, according to Mr T. Arnold, is neither Northumbrian nor East Anglian, but with some slight Northumbrian exceptions, the pure literary Anglo-Saxon of Wessex; and the poem must be referred to a very early stage of Anglo-Saxon culture, when Christianity, though it had been introduced, had not yet supplanted the fierce joy in fighting, in song, and feasting and seafaring, so characteristic of the old Norse heathendom. The poem in its present form may be assigned with some degree of confidence to an early period in the 8th century;

but it is a hazardous matter to determine whether it was originally carried by our forefathers from the Continent, and afterwards rewritten and worked up into literary form by a late Anglo-Saxon editor, or was entirely due to the invention of an early but native Anglo-Saxon poet. Of course the poem, as we have it, has undergone considerable alterations, and contains many interpolations. Mr Sweet's opinion is that it is a poem composed before the Teutonic conquest of England. The localities are purely continental: the scenery is laid among the Goths of Sweden and the Danes; in the episodes the Swedes, Frisians, and other continental tribes appear, while there is no mention of England, or the adjoining countries and nations. It is evident that the poem, as a whole, cannot have been composed directly from the current traditions of the period: the variety of incidents, their artistic treatment, and the episodes introduced, show that the poet had some foundation to work upon, that there must have been short epic songs about the exploits of Beowulf current among the people, which he combined into a whole. In the poem, as it stands, we can easily distinguish four elements: the prologue, the two chief exploits of Beowulf against Grendel and the dragon, and the episodes.

Ettmüller and Müllenhoff believe the work to be an amalgam of several poems, the latter maintaining that it is made up of four distinct lays or *Heldensagen*, written by at least four hands, the introduction again being due to a still later writer; while each lay has been enlarged by later interpolations, which are detailed with all the certainty and boldness of the true German critic. This ingenious reasoning wears on its face, in the absence of direct contrary evidence, a delusive air of accuracy. It is a matter of great difficulty to determine how much history and how much romance or myth there is in the old poem of *Beowulf*. Thorpe thought it was a metrical paraphrase of an heroic saga, composed in the south-west of Sweden in the old common language of the north, and probably brought to this country during the sway of the Danish dynasty. Kemble, in his edition of the text (1833), assumed the leading characters of the poem to be historical, and assigned the events to the commencement of the 5th century, but in his translation four years later he assigned the incidents of the poem to the poetical cycle of the Angles, seeing in the central figure a god rather than a man with superhuman attributes of defending, protecting, and redeeming the people. Grein and Mr T. Arnold discover in the poem an historical foundation, the former considering that it treats of actions done among the Danes in Denmark, the latter recognising in King Hygelac the historical King Chacilagus spoken of by Gregory of Tours, as well as in the *Gesta Regum Francorum*. Mr Haigh is the originator of a bold but untenable theory which claims for the poem a purely English origin, as the composition of a Northumbrian *scop* familiar with the scenes described, and identifies many of the places mentioned in the poem with localities on the Yorkshire coast. With this Professor Henry Morley substantially agrees, thinking that the poem was originally a Danish tale made English by a poet who lived in the Whithy district, and who, when he described or suggested scenery, produced impressions from the only scenery he knew. Professor Earle believes that the poem is Anglian, and was written in the reign of Offa, king of Mercia, between the years 755 and 794, its aim being to set up an heroic example as the institution of a prince. The central figure is mythical, but in all points exemplary, and particularly resembling King Offa. He thinks further that the saga was probably written originally in Latin, and most likely came out of Frankland to the hands of the English poet.

Professor Skeat, in the *Journal of Philology* (No. 29, 1886), assumes Beowulf to have been a real hero, and Grendel a bear, and sees in the poem a glorified poetical account of some great fight with a bear that impressed itself on the popular imagination. The name *Grendel* means 'the grinder,' and Beowulf, literally the 'bee-wolf,' a name scarcely applicable to any animal but a bear. The former is a name that might well be given to a bear, while the latter might be a nickname for a notable slayer of bears in particular. The learned professor makes out a strong case, but his interpretation is too literal and realistic, and it is hard to conceive that the poetic imagination could have worked so richly round so simple and ordinary a story. German scholars like Müllenhoff have read the whole story into myth, and harmonised it with the legends of nature that form part of the old northern mythology. Simrock, again, recognises the god Thor under the mask of Beowulf, and compares the dragon-fight to Thor's final battle with the Midgard snake, at the close of which he perishes of his venom. It is most likely that in the action of the poem, to some extent at least, real events are described, transformed though they may be into legendary marvels; yet the manners and customs of the old makers of England are accurately painted withal, and its descriptions of wild nature, with its half-spiritual aspects, mark the beginning of what was yet to be a characteristic note in the latest English poetry. The old heathenism, with its strong nature-worship and fatalism, is but thinly veiled by the Christianising touch of its old English editor. Indeed such a passage as that in which Grendel is described as a descendant of Cain, is an example of an interpolation that corresponds but indifferently with the general heathen colouring of the poem. The poem was first edited by Thorkelin (Copenhagen, 1815), next by Kemble (London, 1833), Thorpe (1855), Thomas Arnold (1876), and Harrison and Sharp (1883). German editions are those of Heyne (1863); Grein (1867; re-edited by Wülcker, 1881); Zupitza, an autotype of the MS. (1882); Möller (Kiel, 1883); and Holder (Freiburg, 1884). Translations in English are those of Kemble (1837), Thorpe, and Arnold, the last two accompanying editions of the texts, Lumsden's (1881) in ballad metre, Garnett's (1883), and William Morris's (1895). German translations are Etmüller's (1840) and Simrock's (1869). See Dederich, *Historische und Geographische Studien zum Beowulf-Lied* (1877); Mr Sweet's 'Sketch of the History of Anglo-Saxon Poetry' in vol. ii. (1871) of Hazlitt's edition of Warton's *History of English Poetry*; vol. i. of Henry Morley's *English Writers* (1887); Prof. Earle's *Deeds of Beowulf* (1892); and A. J. Wyatt's edition (with textual notes, 1894).

Bequeath (A.S. *biewethan*), a word meaning originally to declare, and in the technical language of English law, to leave personal property by will to another. In Scots law the words bequeath and bequest are less used than in England. In both countries the expression 'leave and bequeath' is appropriate to the disposal of personal property, but in neither country would the courts defeat the intention of a testator to include his heritable or real estate, if that intention sufficiently appeared. See LEGACY, WILL.

Béranger, PIERRE JEAN DE, the greatest songwriter of France, was born on the 19th August 1780, in the street of Montorgueil, in Paris. His father, a notary's clerk, had left his mother six months after their marriage, and Béranger was brought up by his grandfather, Champy, a tailor, until his ninth year, when he passed into the care of an aunt who kept an inn in the suburbs of Péronne. She was an

ardent republican, and appears to have taken pains to imbue her nephew with her political principles. From his fourteenth to his seventeenth year Béranger worked as apprentice to a printer in Péronne. He afterwards acted as a clerk to his father, who about this time gained a fortune by financial enterprises, only to lose it, however, in 1798. Béranger then settled in Paris, and gave himself to literature, living in the garret of which he has sung so charmingly, planning the most ambitious works (among them an epic on Clovis), and making careful studies of French style, until in 1804 distress compelled him to ask aid from Lucien Bonaparte. The assistance sought was willingly given; and about three years later the poet Arnault found Béranger a clerkship in the office of the Imperial University, a post which he held until 1821. On the publication of the first collection of his songs in 1815, he was recognised as the lyrical champion of the opposition to the Bourbons. His popularity with the working-classes was immense. It was for them that he always wrote, and they repaid him with an ardour of gratitude and admiration such as no other poet has excited in modern times. The *chanson*, in which the 18th-century writers had trifled in praise of love and wine, became in his hands a trenchant political weapon.

His politics, a curious compound of republicanism and devotion to the Napoleonic legend, exactly hit the taste of the multitude. His songs passed from mouth to mouth before they were published; since the invention of printing he is the only poet, it has well been said, who might have dispensed with the services of the press. For a time the government did not interfere, but two volumes which he published in 1821 led to a trial, at the close of which he was fined 500 francs and sentenced to three months' imprisonment in St Pélagie. Another volume, issued in 1825, was the cause of a second prosecution. Béranger was on this occasion fined 10,000 francs and condemned to nine months' imprisonment in La Force, where he was visited by Hugo, Dumas, Sainte-Beuve, and others of the greatest men of the day. In 1830 he published *Chansons Nouvelles*, and in 1840 he wrote the story of his life. In 1848 he was elected, against his will, by more than 200,000 votes to represent the Department of the Seine in the Constituent Assembly. He took his seat, but a few days afterwards begged to be allowed to resign. He rejected sundry offers of advancement from Napoleon III., and lived in retirement during his last years. He died at Paris on July 17, 1857. Béranger has been repeatedly compared to Burns, but he has neither the passion nor the deep humour of the Scottish poet. His songs cover a wide variety of subjects. Their vivacity and wit and tripping lightness of movement, their spontaneity and humanity, their gaiety which trembles into pathos, their satire which melts into laughter, their inimitable simplicity and seemingly unstudied grace of workmanship, explain and justify the unequalled popularity which their author secured and still retains among his countrymen. See *Ma Biographie* (Paris, 1857), and his correspondence edited by Boiteau (4 vols. 1859-60); also Jules Janin's *Béranger et son Temps* (Paris, 1866); W. Besant's *French Humorists* (Lond. 1873); and W. H. Pollock's *French Poets* (Lond. 1879).

Berar, or HYDERABAD ASSIGNED DISTRICTS, a province of Central India, forming a commissionership under the resident of Hyderabad (Haidarabad). It is bounded on the N. and E. by the Central Provinces, on the W. by Bombay, and on the S. by the Nizam's dominions. Its length from east to west is about 150 miles, and its average breadth 144 miles; area, 17,711 sq. m.; pop. (1891) 2,896,670. The province consists of the districts of Amraoti, Ellichpur, Wun, Akola, Buldana, and

Basim, assigned to the British government under the treaties of 1853 and 1861 with the Nizam of Hyderabad, who was bankrupt, and unable to pay a large and increasing debt. The province is mainly a broad valley running east and west, between the Satpura Range in the north and the Ajanta Range on the south, and is divided into the *Balughat* or upland country, and the *Paganghat* or lowland country. The valley at the base of the Satpuras, consisting of black loam, is extremely fertile, and is one rich sheet of waving crops in harvest time. It is traversed in its length by the Purna—itself a tributary of the Tapi—which, with its numerous alluents, affords an ample supply of water to the valley, and it is thus peculiarly suitable to the cultivation of cotton, forming indeed the richest and most extensive cotton-field in India. The other products are millet, oil-seeds, wheat, pulses, tobacco, and castor-oil. Beds of coal are found near the Wardha River, in the Wun district; iron ore is plentiful in the east, and the only natural lake is the salt Lake of Louar. The Great Indian and Peninsular Railway runs through the province from east to west. Ellichpur (pop. 26,728) was the capital of the old kingdom. The British, under General Wellesley, helped the Nizam in 1803 to crush the Mahara power.

Berat', a town of Albania, Turkey, in the province of Janina, 30 miles N.E. of the seaport of Avlona. It is the seat of a Greek archbishop. Pop. about 12,000, a third of whom are Greeks.

Berber. a town on the right bank of the Nile, below the confluence of the Atbara. It is a station on the route from Khartoum to Cairo, and a point to which caravans come from Suakin on the Red Sea. In the course of General Graham's operations against Osman Digna in 1885, a railway was projected from Suakin to Berber, and the work was actually begun, but was ultimately abandoned when military protection was taken away. The pop. is about 8000.

Ber berah. a seaport of Somali, Eastern Africa, with a good harbour, on a bay of the Gulf of Aden. It was conquered by Egypt in 1875, but in July 1884 the British government took possession of it, and a small Indian force is now stationed here. It is the scene of a large annual fair, which brings over 30,000 people together from all quarters in the East. Coffee, grains, ghee, gold-dust, ivory, gums, cattle, ostrich feathers, &c. are brought hither from the interior, and exchanged for cotton, rice, iron, Indian piece-goods, &c.

Berberidææ. or BERBERIDACEÆ, a natural order of thalamifloral dicotyledons, of which the different species of Barberry (q.v.) afford the best-known examples. Many of the plants of this order are spiny shrubs; others are herbaceous perennials. Their leaves are alternate; their flowers are usually in racemes, and are readily characterised by their trimerous symmetry and recurved anther valves; the fruit is either a berry or a capsule, and is usually acid, bitter, or astringent. There are more than 100 species, widely distributed through the temperate zone and on the mountains of the tropics, but absent from South Africa and Australasia.

Berbers. the general name usually given to the tribes inhabiting the mountainous regions of Barbary and the northern portions of the Great Desert. It is derived, according to Barth, either from the name of their supposed ancestor, *Ber*, which we recognise in the Lat. *A-fer*, an African, or from the Greek and Roman term *Barbari*. The name by which they call themselves, and which was known to the Greeks and Romans, is Amázigh, Mazigh, Mazys, &c. according to locality, and

whether singular or plural. These tribes have a common origin, and are the descendants of the aboriginal inhabitants of Northern Africa. They belong to the Hamitic family, and though they have been conquered in succession by the Phœnicians, Romans, Vandals, and Arabs, and have become, in consequence, to some extent a mixed race, they retain in great part their distinctive peculiarities. Till the 11th century, the Berbers seem to have formed the larger part of the population inhabiting the southern coast of the Mediterranean, from Egypt to the Atlantic Ocean; but, on the great Arab immigrations which then took place, they were driven to the Atlas Mountains, and to the desert regions where they now live. In Tripoli, the allegiance they pay to the Turks is little more than nominal; in Algeria, where they usually are termed Kabyles (*K'bila* = 'union'), they long remained unconquered by the French; and in Morocco, where they are called Shelluh, they are only in form subject to the sultan. The Berbers occupying the desert, who are called Tuareg or Tawarek, by the Arabs, have become much mixed with the negro race. The number of the Berbers is estimated at between three and four millions. They are of middle stature, sparely but strongly built, and the complexion varies from reddish to yellowish brown. Their manners are austere, and in disposition they are cruel, suspicious, and implacable. They are usually at war either with their neighbours or among themselves, and are possessed of a wild spirit of independence, which makes it impossible for them to unite for any common purpose. They live in clay huts and tents, but in their larger villages they have stone houses. They have herds of sheep and cattle, and practise agriculture. The mines of iron and lead in the Atlas are wrought by them, and they manufacture swords, guns, and gunpowder. They formerly professed the Christian religion, but are now bigoted adherents of Islam. A *Dictionnaire Français-berbère* was prepared by Brosselard and Joubert (1844). See also Renan, *La Société Berbère*; Jules Lionel, *Races Berbères* (1894); and René Basset, *Contes Berbères*, with list of books on the Berbers and their language appended (1887). See AFRICA.

Berbice', the eastern division of British Guiana (q.v.), bounded on the E. by the Corentyn and Dutch Guiana. Area about 21,000 sq. m. Once a separate colony, Berbice was united with Essequibo and Demerara under one government in 1831. The chief product is sugar, with rum, molasses, timber, cocoa, and tropical fruits. The forests abound with splendid timber-trees, including the mora and bullet-tree. The Berbice River is navigable for small vessels 175 miles from its mouth. An important affluent is the Canje. New Amsterdam, on the right bank of the Berbice River (pop. 9000), is the chief town and port of the district. See GUIANA.

Berchem. or BERGHEM, NICHOLAS, an eminent Dutch painter, was born at Haarlem in 1620, and having studied under his father and Van Goyen, Weenix the elder, and other masters, he spent several years in Italy, where he soon acquired an extraordinary facility of execution. His industry was naturally great; and his innumerable landscapes now decorate the best collections of Europe. The leading features of Berchem's works, besides the general happiness of the compositions, are warmth of colouring, a skilful handling of lights, and a mastery of perspective. His etchings are also highly esteemed. He died in 1683.

Berchemia. See SUPPLE JACK.

Berch'ta (modern form *Bertha*, the old High German *Perahtha*, 'the bright'), a goddess of South German mythology, apparently the same as the

Hulda ('the gracious') of Northern Germany. In Dame Hulda, the gracious and kindly aspect came to be the predominant; but in Dame Berchta, the severe and awe-inspiring, the reason for this being that the popular Christian view had degraded her lower than Hulda. Dame Berchta has the oversight of spinners; whatever spinning she finds unfinished on the last day of the year she spoils. Her festival is kept with a prescribed kind of meagre fare—oatmeal-gruel, or pottage, and fish. If she catches any one eating other food on that day she cuts his stomach open, fills it with chopped straw, and sews up the gash with a ploughshare for a needle, and an iron chain for a thread. She is represented in some places as having a long iron nose and one big foot. It is likely that many of the attributes of Berchta were transferred to the famous Berthas of medieval history and fable, as Berta, wife of King Pippin and mother of Charlemagne. She has been connected with the feast of the Epiphany (6th January), and has been explained by some as a personification of the brightness of the heavenly vision that appeared to the shepherds in the field; but it is far more likely that the analogy of the 'bright' day was tacked on to a previously existing Perhta, a deity of heathendom. The numerous stories of the 'White Lady' (q.v.) who appears in noble houses at night, and acts as the guardian angel of the race, have doubtless their root in the ancient heathen goddess Berchta.

Berchtesgaden, a village of Bavaria, charmingly situated on a mountain-slope, about 15 miles S. of Salzburg. Its abbey is now a royal castle, and in the neighbourhood is a royal hunting-lodge. The place is most remarkable for its government salt-mines, from which 150,000 cwt. of rock-salt are annually obtained. Fresh water being introduced to the mine, it is run off as brine into a reservoir, and afterwards conducted to Traunstein and Rosenheim, about 40 miles distant. Pop. 2197, mostly Catholics.

Berck-sur-mer, a harbour and bathing resort in the French department of Pas-de-Calais, 22 miles S. of Boulogne, with some shipbuilding and sailmaking. Pop. 5752.

Berdiansk', a seaport of Southern Russia, in the government of Taurida, on the NW. coast of the Sea of Azov. It has the finest harbour in the Sea of Azov, and is a place of commercial activity. Pop. 23,593.

Berditchef, a town of Russia, 108 miles WSW. of Kiev by rail, famous for its five annual fairs. At these, cattle, corn, wine, honey, leather, &c. are disposed of. The average annual value of the sales is £600,000. Pop. 98,234, largely Jews.

Bere, a kind of Barley (q.v.).

Bereans, an almost extinct sect of Christians, who originated in Scotland in the 18th century. They took this name from the people of Berea, who are spoken of in Acts, xvii. 11, as having 'received the word with all readiness of mind.' Their founder was the Rev. John Belalay (1734-98), a native of Muthill, in Perthshire, who acted as assistant minister at Fettercairn for nine years. They believe that the knowledge of God's existence and character is derived from the Bible alone, and not from reason or nature; that the Psalms of David relate exclusively to Christ; that assurance is of the essence of faith; and that unbelief is the unpardonable sin. In other points of doctrine they are ordinary Calvinists.

Beregonium is a misprint in the Ulm edition of Ptolemy's Geography (1486) for *Rerigonium*, a town of the Novante, now identified with the fort of Innermessan on the east shore of Loch Ryan. Boece applied the name Beregonium to a large

vitrified fort in Ardehatten parish, Argyllshire, 5½ miles NNE. of Oban. But there is no historical ground for supposing this to have been a seat of ancient kings, Scottish or other, as is often assumed.

Be'ngar I., king of Italy, succeeded at his father's death to the dukedom of Friuli. After the deposition of Charles the Fat in 887, he was crowned king of Italy, but he soon irritated the nobles by condescending to hold his territory in fief from Arnulf, king of Germany; and Guido, Duke of Spoleto, was persuaded to contest the throne. With the help of Arnulf, however, Berengar ultimately prevailed. After Guido's death in 894, his son, Lambert, compelled the king to share with him the sovereignty of North Italy until 898, when Lambert was assassinated. Berengar's influence quickly sank, since he could not check the plundering incursions of the Magyars and Arabs, and many years were spent in struggles to maintain his position. In 915 he was crowned emperor by Pope John X.; but the nobles again revolted, and under Rudolf of Burgundy completely overthrew him in 923. In his extremity, Berengar called in the Hungarians to his aid, which unpatriotic act alienated the minds of all Italians from him, and cost him his life, for he was assassinated in 924.—**BERENGAR II.**, grandson of the preceding, succeeded his father as Count of Ivrea in 925, and married Willa, niece of Hugo, king of Italy, in 934. For a conspiracy against Hugo, he was compelled to flee to Germany, where he was kindly received by the emperor, Otto I. In 945 he recrossed the Alps at the head of an army, and placed the weak Lothaire, the son of Hugo, on the throne. On the death of this prince, who was probably poisoned by Willa, Berengar allowed himself to be crowned along with his son, Adalbert, in 950. His tyranny induced his subjects to call in the aid of the emperor, who marched into Italy in 961, and took possession of the country. After three years' refuge in a mountain-fortress, Berengar surrendered, and was sent as a prisoner to Bamberg, in Bavaria, where he died in 966.

Berengaria. See RICHARD I.

Berengar'ius OF TOURS, a distinguished scholastic theologian, was born at Tours, in France, 998 A.D. In 1031 he was appointed preceptor of the school of St Martin in Tours, and, about 1040, archdeacon of Angers. Here he first drew upon himself the charge of heresy in reference to the doctrine of transubstantiation. He held that the bread and wine in the sacrament of the eucharist remained bread and wine, and that the faith of the believer who recognised their symbolic meaning only transformed them subjectively into the body and blood of Christ. This interpretation was condemned by Pope Leo IX. (1049-50). In 1054 Berengarius retracted his opinion before the Council of Tours, but immediately returned to his conviction, and commenced to advocate it anew. For this he was finally, in 1078, cited to appear at Rome, where he repeatedly abjured his 'error,' but never seems to have really abandoned it. Hildebrand, now Pope Gregory VII., treated him with great moderation; and at last conceived it best to let him alone. Harassed and weakened by the attacks of the orthodox party, headed by Lanfranc of Canterbury, he finally retired to a cell at St Côme, on an island in the Loire (now a ruin on the south bank), near Tours, where he spent the last years of his life in devotional exercises. He died in 1088. The greater number of his works are lost; such as are extant have been collected and published by A. F. & F. T. Vischer (Berlin, 1834).

Bereni'ce (modern name, *Sakáyt-el-Kubli*), a town of Egypt, on a bay in the Red Sea, 20 miles

SW. of Ras Benass. It was founded by Ptolemy Philadelphus, and was in ancient times the emporium of the trade with India, but it is now ruined, and interesting only for its antiquities.

Berenice, the name of several celebrated women of the house of Ptolemy, including (1) the wife of Ptolemy I., celebrated by Theocritus; the daughter of Ptolemy II.; and the wife of Ptolemy III. This last queen, during the king's wars in Asia, made a vow to offer her beautiful hair to the gods when her husband returned safely—a vow which she fulfilled. The hair was suspended in the temple of Aphrodite, from which, according to the fable, it was taken to form a constellation, *Coma Berenices*.—(2) **BERENICE**, also called Cleopatra, daughter of Ptolemy IX. (Lathyrus), was, on her succession to the throne, married to Alexander II., by whom she was murdered nineteen days after marriage.—(3) **BERENICE**, daughter of Ptolemy XI. (Anletes), eldest sister of the renowned Cleopatra, was raised to the throne after her father's deposition, 58 B.C., but was put to death when her father was restored, 55 B.C. She was first married to Selencus, whom she caused to be put to death, and afterwards to Archelans, who was put to death with her.—There were, besides, two Jewish Berenices—the one, daughter of Salome, sister of Herod the Great, and mother of Agrippa I.; the other, and more famous, was daughter of this latter monarch. She was three times married: her uncle, Herod, Prince of Chalcis, left her for the second time a widow, at the age of twenty; and she deserted her third husband to return to her brother, King Agrippa II., the same before whom Paul defended himself at Cæsarea. After the capture of Jerusalem, she went to Rome, and Titus, who was much in love with her, would have married her but for the opposition of the people. The intimacy of Berenice and Titus forms the subject of a tragedy by Racine.

Beresford, **WILLIAM CARR BERESFORD**, VISCOUNT, general, was born in 1768, a natural son of the first Marquis of Waterford. He entered the army in 1785, in 1786 lost his left eye through an accident, and, after serving in all the four continents, bore a conspicuous part (1806) in the reconquest of the Cape, and the capture of Buenos Ayres. The latter achievement was followed by his own surrender, but in 1807 he made his escape. In 1808 he did gallant service during the retreat to Coruña; and in 1809 he took the command of the Portuguese army, with the local rank of lieutenant-general. He succeeded in improving its discipline so greatly, as soon to render it highly efficient for active service. For his services at Busaco (1810) he was made a Knight of the Bath; and for his victory over Soult at Albuera (1811) he received the thanks of parliament. He was present at Badajoz, and at Salamanca, where he was severely wounded, and distinguished himself in many other battles. In 1814 he was created Baron, and in 1823 Viscount, Beresford. He quitted Portugal in 1822; and in the Wellington administration (1828-30) he was master-general of the ordnance. He bore the title of Duke of Elvas in Spain, and of Comte de Trancoso in Portugal. He died, without issue, 8th January 1854, when his title became extinct.

Beresina, or **BEREZINA**, a river of Russia, having its rise in the north of the government of Minsk in Lithuania. It flows in a southward direction for about 350 miles (over 200 of which are navigable) to the Dnieper. Its shores are flat, and the stream is of importance as a means of floating the timber of the country to the sea in rafts. It is connected with the Duna, or Dwina, by a canal, a communica-

tion between the Black and Baltic Seas being thus established. The Beresina is memorable on account of the disastrous passage of the French army, November 1812, during the retreat from Moscow. Two bridges over the river were hastily constructed amid terrible hardships, and, on the 27th, the passage of the French commenced, and went on throughout the whole day. Marshal Victor's rear-guard of 7000 men, under Partonneaux, were, however, intercepted by the Russians, and had to capitulate. On the 28th a vigorous attack was made by the Russians upon the French on both sides of the river; and they established a battery of twelve pieces to command the bridge. The panic and confusion of the French became dreadful. One bridge broke, and all rushing to the other, it was soon choked; multitudes were forced into the stream, while the Russian cannon played on the struggling mass. On the 29th a considerable number of sick and wounded soldiers, women, children, and sutlers still remained behind, until preparations were completed for burning the bridges. Then a fearful rush took place; and as the fire seized the timbers, men, women, and children threw themselves in desperation into the flames or the river. The 12,000 dead bodies found on the shores of the river, when the ice thawed, attested the magnitude of the French disaster. The Russians took 16,000 prisoners and 25 pieces of cannon.

Bereslav, or **BERSLAV**, a thriving town in the Russian government of Kherson, on the Dnieper, trading in wood and corn. Pop. 11,093.

Berezna, a town of Russia, 30 miles E. of the town of Tchernigoff, on a tributary of the Desna. Pop. 11,806 (many Jews).

Berezov' ('the town of birch-trees'), a town of Siberia in the government of Tobolsk, on the left bank of the Sosva, a branch of the Obi. It marks the northern limit of the region of rye, barley, and horses, and is important as a fur and skin trading station. Pop. 2000, made up of Cossacks and exiles.

Berezovsk, a village in the Russian province of Perm, near Ekaterinburg, gives name to a famous gold-field, wrought since 1744. The mines are on the eastern slopes of the middle Ural chain, and the field is above 5 miles long. The washings on the Berezovka River are also very productive.

Berg, a former duchy of Germany, on the right bank of the Rhine, now incorporated with the Prussian dominions, between Düsseldorf and Cologne. It is a densely populated manufacturing country. After various vicissitudes, the duchy had merged in the electorate of Bavaria, and in 1806 Bavaria ceded it to France. Napoleon erected it into a grand-duchy, constituting his brother-in-law, Murat, its sovereign; and two years afterwards, Napoleon's nephew, then Crown Prince of Holland, was made grand-duke. The peace of 1815 gave Berg to Prussia.

Berg, **CHRISTIAN PAULSEN**, Danish politician, born in 1829, near Lemvig, in Jutland, in 1865 entered the Folksting, of which he was chosen president in 1883. In 1877 he became leader of the Radical opposition, and in 1881 editor of the *Morgenblad*; in 1886 his fierce attacks on one of the ministry brought on him six months' imprisonment. He died 27th November 1891.

Berga, a town of Catalonia, Spain, 52 miles NNW. of Barcelona. Pop. 5000.

Ber'gama (ancient *Pergamos*), a city of Asiatic Turkey, province of Aidin, situated in a beautiful and fertile valley, 40 miles N. of Smyrna. In early times the city was the capital of the kingdom of

Pergamum (q.v.). The present population is about 6000.

Bergamo (the ancient *Bergomum*), a fortified town of Lombardy, situated on low hills, 34 miles NE. of Milan by rail. It has a castle occupying the most elevated part of the town, a cathedral, school of art, museum, lyceum, library, two theatres, &c. Silk, cotton, linen, woollen fabrics, and iron goods are manufactured. It has also an extensive trade in grindstones, quarried in the vicinity. Annually, in the month of August, the largest fair in Northern Italy is held here. Bergamo was destroyed by Attila, 452 A.D.; after the fall of the Roman empire, it became capital of a Lombard duchy, and its inhabitants placed themselves under the protection of the Venetian Republic in 1427. It is now capital of an Italian province. Tiraboschi and Donizetti were natives of Bergamo, and Bernardo Tasso, the father of Torquato, was of Bergamasco descent. Pop. (commune, 1892) 42,500.

Bergamot is the name applied to a group of varieties of pear, which agree in more or less completely resembling an apple in shape, in melting juicy pulp, and pleasant flavour. See PEAR.

Bergamot is also the name of a species or variety of the genus *Citrus* (q.v.), also called the BERGAMOT ORANGE, or MELLAROSA; by some botanists regarded as a variety of the orange (*C. Aurantium*); by others, as a variety of the lime (*C. limetta*); and elevated by Risso to the rank of a distinct species, under the name of *C. bergamea*. The name comes from Bergamo (q.v.), a city in Asia Minor, the ancient Pergamos. It is now cultivated in the south of Europe; and from the rind of its fruit, the well-known Oil of Bergamot is obtained, which is extensively used in making pomades, fragrant essences, eau de Cologne, liqueurs, &c. The fruit is pear-shaped, smooth, of a pale-golden colour, and has a green, subacid, firm, and fragrant pulp. The essential oil is obtained by distillation, or by grating down the rinds, and then subjecting them to pressure, which is the better method. The oil is also obtained from other varieties or species of the same genus. It is of a pale-yellow colour or almost colourless. One hundred Bergamot oranges are said to yield about 2½ ounces of oil. Oil of Bergamot is frequently employed for diluting or adulterating the very expensive blue volatile oil of Chamomile (q.v.).—BERGAMOT is also applied to certain fragrant Labiates, notably *Mentha citrata* or *odorata*, as also to species of *Monarda* (*M. fistulosa*, &c.).

Bergedorf, a district and town of Germany, 10 miles SE. of Hamburg, to which it belongs. Part of the territory is known by the name of the Four Lands (*Vierländer*). It is inhabited by a well-conditioned and industrious population, much occupied in the cultivation of fruit and vegetables, not only for the market of Hamburg, but for that of London. The area is 35 sq. m., and the population about 20,000. Pop. of town, 6957.

Bergen, a fortified seaport in the west of Norway, and the second city of the kingdom, in the province of the same name, situated on a promontory at the head of a deep bay, and, with the exception of the north-east side, where lofty mountains inclose it, surrounded by water. The harbour is safe and commodious, and around it the town is built, presenting a picturesque appearance from the sea, with its wooden houses of various colours. It has a cathedral, various churches, schools, hospitals, and public institutions; and is the seat of a bishop, and the station of a naval squadron. The museum has valuable collections of Norse antiquities and specimens of

Norwegian fishes. The chief manufactures of Bergen are gloves, tobacco, porcelain, leather, soap, and cordage. It has numerous distilleries, and several shipbuilding yards. Its principal trade, however, is the export of stockfish, herrings, and fish-oil and roe. Twice a year, the Norlandmen come to Bergen with their fish, receiving in exchange for them such articles of necessity or luxury as they require. The annual value of the stockfish exported from this port is about £450,000. In addition, it exports about half a million barrels of herrings and 20,000 barrels of cod-liver oil. There is constant steam communication with Copenhagen, the Baltic ports, Hamburg, Rotterdam, Hull, Newcastle, and New York. Since 1883 Bergen has been connected by railway with the north of the Hardangerfjord. The chief imports are brandy, wine, corn, cotton, woollens, hemp, sugar, tobacco, coffee, &c. The climate is exceedingly humid, but not unhealthy; the yearly rainfall is 89 inches, and the temperature averages 46° F. Bergen, formerly called Björgvin ('the pasture betwixt the mountains'), was founded about 1070 by Olaf Kyrre, who made it the second city in his kingdom, and it was soon raised to the first rank. English and Scottish traders were early displaced here by the merchants of the Hanse towns, who continued to exercise and abuse their monopoly until their supremacy was broken by an act issued by Frederick II. of Denmark in 1560; and in 1763 their last warehouse fell into the hands of a citizen of Bergen. In the 13th century, Bergen had thirty churches and religious houses, but these have been mostly swept away in the numerous conflagrations which have devastated it from 1189 to 1855. The town was long the most important trading town of Norway, but has been recently surpassed by Christiania. The castle of Bergenhus was till 1397 the residence of the Norwegian kings. Bergen was the birthplace of Holberg, the painter, Dahl, Welhaven, and Ole Bull. Pop. (1891) 52,083.

Bergen-op-Zoom, a town formerly strongly fortified, in the Dutch province of North Brabant, 21 miles N. by W. of Antwerp, and 39 E. by N. of Flushing. It stands on the little river Zoom, at its entrance into the east branch of the Scheldt, in a marshy district, frequently inundated. It has a harbour, manufactures of brick and earthenwares, and a large trade in anchovies. Population, 11,108. The importance of its position rendered the town the object of many contests. The Netherlands made it one of their strongholds in their struggles with Spain, and the Spaniards, who had been expelled in 1577, unsuccessfully attempted to capture the place, either by siege or storm, in 1581, 1588, 1605, and 1622. The fortifications were afterwards strengthened by the engineer Coehorn, so as to give it the reputation of being impregnable. Yet the French, under Count Löwendal, in 1747, after a siege of nearly three months, and the springing of 41 mines by the assailants, and 38 by the defenders, took the place by storm, and in 1795 it capitulated without resistance to Pichegru. Being incorporated with France in 1810, it was blockaded in 1814 by the English, who attempted to surprise the fortress on the night of the 8th of March with a force of 3900; but after carrying the greater part of the works, they were, through Sir Thomas Graham's remissness in sending support, overpowered by the brave garrison, and either slain or forced to surrender. The French only gave up the post under the Treaty of Paris; in 1867 the fortress was demolished.

Bergenroth, GUSTAV ADOLF, historian, born in Prussia, 1813, studied law, and entered the state service, from which he was dismissed, owing to his

revolutionary views, in 1848. Becoming further compromised, he went to America in 1850, but settled in 1857 in England, where he devoted himself to the study of the state papers of the Tudor reigns. After a visit to Simancas, in Spain, the results of his labours were published under the title *Calendar of Letters, Despatches, and State Papers relating to the Negotiations between England and Spain* (3 vols. Lond. 1862-68). He died in Madrid, February 13, 1869.

Bergerac, a town in the French department of Dordogne, on the Dordogne, 60 miles E. of Bordeaux by rail. Most of its inhabitants are employed in the surrounding ironworks and paper-mills. The wines of the district, both white and red, are esteemed. During the wars with the English, Bergerac was a fortress and an entrepôt of trade; but after siding with the Calvinists, and consequently suffering greatly in the religious wars, the place was dismantled by Louis XIII. in 1621, whilst the revocation of the Edict of Nantes drove many of its citizens into exile. Pop. (1891) 12,485.

Bergerac, SAVINEN CYRANO DE, a French author, born in Paris, 1619, distinguished for his courage in the field, and for the number of his duels, more than a thousand, most of them fought on account of his monstrously large nose. He died in 1655. His writings, which are often crude, but full of invention, vigour, and wit, include a tragedy, *Agrippine*, and a comedy, *Le Pèlant Joli*, from which Corneille and Molière have freely borrowed ideas; and his *Histoire Comique des Etats et Empires de la Lune et du Soleil* probably suggested 'Micromégas' to Voltaire, and 'Gulliver' to Swift. His works have been frequently republished, the last time at Paris, 1875.

Berghaus, HEINRICH, an eminent geographer, was born at Cleves, in Rhenish Prussia, in 1797. His early services as an engineer in the French and Prussian armies largely advanced his knowledge of geodesy. After being employed on the trigonometrical survey of Prussia, he became (1824) professor of Mathematics in the Architectural Academy of Berlin, and (1836) director of the Geographical School in Potsdam. The best-known of his cartographical works is his *Physical Atlas* (90 plates, 2d ed. 1852). He edited several geographical periodicals, and wrote numerous valuable works on physical and political geography, including the *Land- u. Völkerkunde* (1840). His correspondence with A. von Humboldt, published at Leipzig in 1863, fills 3 vols. He died at Stettin, 17th February 1884.

Bergk, THEODOR, a distinguished German classical scholar, born at Leipzig, May 22, 1812. From 1842 to 1869 he was professor of Philology successively at Marburg, Freiburg, and Halle. In the latter year ill-health enforced his retirement, and the remainder of his life was spent in preparing his *Geschichte der griechischen Literatur*, of which, however, he finished the first volume only (Berl. 1872), the other three being edited by G. Hinrichs (1883-88). Bergk's chief complete work is his *Poetae Lyrici Graeci* (3 vols. Leip. 1843). He also published numerous papers on philology and editions of individual Greek poets. He died July 20, 1881.

Bergman, TORBERN OLOF, a celebrated Swedish chemist, born at Katharimaberg, in West Gothland, March 20, 1735. A student under Linnaeus at Upsala in 1758, he was raised to the chair of Physics there, and in 1767 to that of Chemistry. Here he continued till his death, July 8, 1784. Bergman's earliest studies were in natural history; his later, in chemistry and mineralogy. His theory of elective or chemical affinities had an

important place in the history of chemistry, and his work in mineralogy did much to prepare the way for a scientific classification of minerals. His dissertations are collected into 6 octavo vols. (Leip. 1779-81); and English translations of them fill 3 vols. (1784-85).

Bergmehl, or MOUNTAIN-FLLOUR, is a recent deposit of a white or cream-coloured powder of extreme fineness, composed almost entirely of the indestructible siliceous frustules or cell-walls of Diatomaceae (q.v.). From its resemblance to flour, it has been mixed with ordinary food in seasons of scarcity, and thus used by the inhabitants of Norway and Sweden, who suppose it to be nutritious. When subjected to a red heat, it loses from a quarter to a third of its weight, the loss consisting probably of organic matter, and this would make it in itself nutritious; but it seems to derive its chief value from its increasing the bulk of the food, and rendering the really nutritious portion more satisfying. On the other hand, some experiments tend to show that bergmehl does contain a very small proportion—3 or 4 per cent.—of positive nutriment. Similar deposits occur at Dolgelly in North Wales, at South Mourne in Ireland, and in Mull, Raasay, Skye, and elsewhere in Scotland. The contained organisms show that these beds have been deposited in fresh water.

Bergues, a town and fortress in the French department of Nord, on the Colme, 5 miles SSE. of Dunkirk. Four detached forts, two of which command the road to Dunkirk, guard the town, which was fruitlessly besieged by the English in 1793. Pop. 5435.

Bergylt (*Sebastes norvegicus*), a common fish in northern seas, belonging to the family Scorpaenidae, in the great order of fishes with spinous rays (Acanthopterygii). It is somewhat like a perch in appearance, and used to be called *Peregrina marina*; no resemblance, however, can justify another of its names—the Norway Haddock. It attains a length of 2 feet or more, has a red colour, and is good for food. Though occasionally found on British coasts as far south as Berwick, its true home is farther north. The genus *Sebastes* includes 24 other widely-distributed species.

Berhampur, the name of two towns in British India.—(1) Berhampur, in Madras, is a military station in the district of Ganjam, 18 miles SW. of the town of Ganjam, and but 9 from the coast. The climate is very healthy, and there is some trade in sugar and silk cloth. Population, 26,653.—(2) Berhampur, in Bengal, on the left bank of the Bhagirathi, 5 miles below Murshidabad. It was long one of the principal military stations in British India, and the barracks, now largely devoted to other uses, still form the most prominent feature of the town. In 1857 Berhampur was the scene of the first open act of mutiny. Pop. 23,515.

Beriberi (from the Singhalese *beri*, 'weakness'), a malady common in India, Japan, and parts of Africa, which combines anæmia, pain, and difficulty in breathing, with dropsical and paralytic symptoms. It may be acute or chronic, and is not contagious, but infests districts.

Bering. See BEHRING.

Berja, a town of Spain, 22 miles W. of Almería. The inhabitants are chiefly engaged in mining lead. Pop. 13,582.

Berkeley, a small town of Gloucestershire, on the Avon, 17½ miles SW. of Gloucester by rail. The town lies in the Vale of Berkeley, which consists of rich meadow pasture-land, on a deep, fat loam, and is celebrated for its dairies and 'Double Gloucester' cheese. Berkeley Castle,

on an eminence to the south-east, about 1162 was granted by Henry II. to Robert Fitzhardinge, with whose descendants it has since continued for more than seven centuries, they having held the title of Baron Berkeley from 1295, and of earl and viscount from 1679. Here Edward II. was murdered in 1327. In the civil wars of Charles I., the castle held out for the king, but was taken after a nine days' siege by the Parliamentarians. Dr Jenner was a native of Berkeley, and was buried in the parish church. Pop. of town, 870. See John Smyth's *Lives of the Berkeleys, from 1066 to 1618*, ed. by Sir John Maclean (2 vols. 1883-84).

Berkeley. a town of Alameda county, California, overlooking the Bay of San Francisco, is the seat of the state university (1400 students). Pop. 5101.

Berkeley. GEORGE, Bishop of Cloyne, an historical figure in the 18th century, whose romantic life of unselfish enthusiasm and self-sacrificing philanthropy animated a metaphysical genius still powerful in philosophical speculation. He was born in the neighbourhood of Kilkenny, on the 12th of March 1685 (N.S.), according to reliable tradition, in the half-ruined castle of Dysert, on the bank of the Nore. He was a scion of the noble House of Berkeley; his mother was a Wolfe, of the same Irish family as the hero who afterwards fell at Quebec. At the age of eleven he was sent to the Duke of Ormond's School at Kilkenny, from which he proceeded, in his fifteenth year, to Trinity College, Dublin. There he continued to reside, as student and fellow, for thirteen years. Trinity College was then influenced by independent thinkers. The philosophy of John Locke, which gave form to, and expressed the spirit of the 18th century, was already in vogue there, and, along with Descartes and Malebranche and the new physics of Newton, was superseding medieval scholasticism. To these stimulating influences the young student from Kilkenny responded with characteristically ardent enthusiasm. A *Commonplace Book* of 1705-6, lately discovered, and first published in the collected edition of his works in 1871, reveals an intellectual fermentation of extraordinary interest. Throughout its pages we see a subtle and original mind, stimulated by Locke's psychology to a conception of the universe which Locke himself never consciously approached.

The ardent spirit of the *Commonplace Book* soon found vent in philosophical authorship. Its 'new principle' was soon given to the world, first in its application only to our visual perception of things, and then, in two succeeding treatises, with philosophical comprehensiveness, as a system of universal immaterialism in which the whole world of sense is spiritualised. Accordingly, in 1709, he produced an *Essay towards a New Theory of Vision*, the purpose of which was to show that the act of seeing, which seems so immediate and indecomposable, is not really a direct and inexplicable revelation of something outside all self-conscious intelligence, but is an act of interpretation, involving a process essentially (if unconsciously) rational, which presupposes too a rational or orderly constitution in the visually interpreted phenomena themselves. The *Essay* is thus a psychological analysis of visual perception, with an ontological outcome. It was Berkeley's first step towards a clarification of the confused popular, and self-contradictory philosophical conceptions of matter, by its translation of the semi-conscious processes of sight into a virtual recognition of the perpetual creative agency of Supreme Reason. The argument was enlarged in scope in a *Treatise on the Principles of Human Knowledge*, in 1710, followed in 1713 by *Dialogues between Hylas and Philonous*, in which the new conception of matter

is popularised. These three books set in motion in Europe a train of speculation which, slow at first, through popular and philosophical misunderstanding, has not ceased since to move human thought about all the ultimate questions of our life and our surroundings. The central conception of the three continued to develop in Berkeley's mind throughout his life. His 'new principle'—that the world which we see and touch is not an abstract independent substance, of which conscious mind may be an effect, but is the very world that is presented to our senses, and which depends for its actuality on being perceived—was long misconstrued as the monstrous paradox that matter has no perceived existence. We are only now learning to realise, through its help, that phenomena in a sense presuppose the presence and continual agency of Supreme Reason; that external nature is thus throughout and always supernatural; that the orderly evolution of its sense phenomena, in inorganic and organic things, interpreted in natural science, is, for mere science, only a succession of phenomena, but that to the eye of philosophy these phenomena are severally and collectively dependent on the immanence of Reason, and ultimately on the moral agency of Spirit—so that the evolution of finite things, even in an endless succession, is in no way inconsistent with their being the subjects of constant creative activity. The material world of Berkeley is just what the senses present: all in it beyond this belongs to the world of mind, which converts the presented phenomena into a language that is expressive of absent sense phenomena, of other finite spirits, and of the all-pervading Reason that is supreme and absolute. What we know beyond sense phenomena is their intelligible synthesis in the form of variously qualified things. Our objective perception of this external or interpretable world is reached, not through any single sense, but through sense symbolism, which enables us to connect what is actually present in one sense with what is conditionally presentable in the others. Belief in the real existence of the external world is belief in the permanence of this intelligible connection among sense phenomena. This belief presupposes that we are in a trustworthy and intelligible universe, in which the sense signals presented to us to regulate our lives by may be depended on. Our security for the reality of the Berkeleyan external world is the thus inevitable assumption that nature is reasonable; that its phenomena express thought akin to our own; that it is more or less interpretable by us in progressive physical or natural science; and that even in the world of the senses we are living and moving and having our being in the supreme all-pervading Reason, theologically called God.

In 1713 Berkeley went to London, and was introduced by his countryman Swift to the statesmen and men of letters who there formed a brilliant society in the reign of Queen Anne. After spending nearly a year in London, he gave seven years to travel in France and Italy, first as chaplain to the brilliant and eccentric Earl of Peterborough, and afterwards as tutor to a son of the Bishop of Clogher. His journals, lately recovered, contain vivid descriptions of this continental experience, including adventures in crossing Mont Cenis in winter, a perilous visit to the crater of Vesuvius during an eruption, and an interview and metaphysical discussion at Paris with the aged Malebranche.

On his return to Ireland in 1721 he was distressed by the symptoms of social corruption and disorder occasioned by the South Sea Mania. This was the beginning of his public career as a missionary-philanthropist in pursuit of ideals for society. His sociological thoughts first found

expression in a short *Essay towards preventing the Ruin of Great Britain*, charged with suggestions economical and ethical, significant of his own chivalrous indifference to wealth. In 1724 he resigned his fellowship in Trinity College, on being made Dean of Derry, with an income of £1100, which put him for the first time in easy circumstances. Yet that very year he carried to London a letter from Swift to Lord Carteret, the lord-lieutenant of Ireland, bearing that it was 'to introduce an absolute philosopher with regard to money, titles, and power, who for three years past has been struck with the romantic notion of founding, by a charter from the crown, a college at the Bermudas for the Christian civilisation of America, where he exorbitantly proposes a whole hundred pounds a year for himself as its head, and whose heart will break if his deanery be not for this purpose taken from him.' With a foresight of our vast colonial empire, he laboured in London for three years to interest Sir R. Walpole and other leading politicians in this missionary project, the grandest conceived in the 18th century. At last £20,000 was voted by the House of Commons for the endowment. On the faith of this he sailed for America in September 1728, taking with him a congenial auxiliary in his newly-married wife. To prepare for Bermuda, he made a romantic temporary home for himself for nearly three years in Rhode Island, where a few years before some American missionaries had settled. In one of them, a Dr Samuel Johnson, he found congenial companionship and a philosophical disciple, whose works, as well as those of Jonathan Edwards, helped to propagate his metaphysical conception of matter in America. Berkeley never reached Bermuda, as the promised grant was in the end withdrawn. In the autumn of 1731 he returned to England, carrying with him literary fruit ripened in Rhode Island, in 'the still air of delightful studies,' and given to the world in 1732 under the title of *Alciphron, or the Minute Philosopher*, the most finished of his works, with pleasant pictures of American scenes and life, while in form and ideas it resembles dialogues of Plato. Its philosophy cannot be out of date as long as agnostic contention with personality in man and God is continued. *Alciphron* was followed in 1733 by a *Vindication* of Berkeley's early visual immaterialism. In the *Analyst*, published in 1735, his theological philosophy was further unfolded, in an argument meant to show that the higher mathematics involve assumptions which as truly exclude definite or exhaustive conception as do any of the mysteries of religion, and which equally with the latter illustrate the spiritual fact, that the ultimate or marginal conceptions of an intelligence like ours must be only half-conceived truths.

Meantime, in 1734, Berkeley was made Bishop of Cloyne, in the south of Ireland, where in a beautiful home-life of eighteen years he found a channel for his ardent philanthropy in devotion to the social problems of Ireland. Two years after he went to Cloyne, he began the publication of the *Querist*, which appeared, in that and the two following years, in three instalments, consisting of about five hundred questions suggested by Ireland, with 'more hints, than original, still unapplied, in legislation and political economy than are to be found in any equal space.' The *Querist* was followed, in succeeding years, by other pamphlets on Ireland, and appeals for a larger toleration of its religious differences. The medical virtues of tar-water, on which he had been experimenting, were characteristically connected in Berkeley's mind with the ultimate conceptions of religious philosophy. In 1744 he published *Siris*, or a chain of philosophical reflections on the virtues of tar-water, a treatise which he said cost

him more research and thought than any of his other works. Through the crude mechanics, chemistry, and physiology of a past age, it suggests a connection between the resinous element in tar and the Spiritual Power by which the universe is being perpetually created. Plato and the Neo-Platonists, the companions of his advancing years, appear here as his authorities, and throw into the background Locke and the empirical teachers of his youth. In *Siris* he traces the steps by which, at the dawn of the Christian era, Greek and Græco-oriental speculation sought to rise towards the Infinite and Ineffable, and to connect the sensible world and the embodied spirits of men in an intellectual unity in the Divine Reason.

The beautiful home-life at Cloyne ended in 1752, when declining health hastened the execution of a long-formed project to resign his episcopate and make Oxford the home of his old age. Six months after he had reached Oxford, on the 14th of January 1753, he suddenly passed from the world of sense. His body was buried in the cathedral of Christ Church.

Berkeley's life has been one of the principal forces in modern philosophy. His thought has indeed been for the most part only unconsciously operative, beneath the shock and sense of strangeness with which, interpreted as an absurd paradox, it has been popularly received. But it is at the root of all the great conflicts of ultimate speculation about the universe in the 18th and 19th centuries. David Hume, looking only at what Berkeley denied, so misapplied the 'new principle' as to disintegrate spirit as well as matter into a succession of isolated feelings; although Berkeley had really resolved even matter, not into isolated feelings, but into a continuous presentation of significant sense phenomena. Reid and the Scottish psychologists were roused to attempt a deeper and truer psychology than Locke's by the desire to refute the Berkeley they saw in Hume. English and French empirical psychology, from Hartley and Condillæ to John Stuart Mill and Comte, has accepted the phenomenalist theory of matter, but emptied of the originating and directing Reason which in Berkeley's thought was its philosophically necessary constitution. In Germany, Kant told that he was roused into philosophical criticism from his 'dogmatic slumber' by the metaphysical nescience which Hume had discovered in his one-sided Berkeley; and the Kantian criticism has formed the European thought of the 19th century, as Lockian psychology formed it in the 18th, and the dogmatic constructions of Cartesianism in the 17th. The abstract self-consciousness of Neo-Kantianism has a certain affinity with the Neo-Platonic idealism of *Siris*—not yet sublimated into Hegelian abstractness in Berkeley's concrete spiritualism, which recognises Reason as at once personal and supreme. It is thus a fact of history that Berkeley has employed the modern philosophical world in a struggle, virtually about his new conception of the universe, which has lasted for nearly two hundred years.

The only complete edition of Berkeley is the Clarendon Press 'Collected Works' (4 vols., Oxford, 1871), annotated with dissertations and a Life by Professor Campbell Fraser, who has also published *Selections from Berkeley* (3d ed. 1884), and *Berkeley* (2d ed. 1885), in Blackwood's 'Philosophical Classics.'

Berkeley Sound, next to Stanley Sound the most frequented inlet of the East Falkland Island, near its north-eastern extremity. Though it is difficult to enter, yet it contains several excellent harbours.

Berkhamstead, a market-town of Hertfordshire, on the small river Bulburn, 28 miles NW.

of London. Straw-plaiting is carried on; and there are manufactures of wooden articles and chemicals. The poet Cowper was a native. Pop. 5034.

Berkovitza, the chief town of a district in western Bulgaria, 40 miles NNW. of Sofia, on a small tributary of the Danube. Pop. 5445.

Berkshire, a midland county of England, bounded N. by Gloucester, Oxford, and Bucks, E. by Oxford and Bucks, SE. by Surrey, S. by Hampshire, and W. by Wiltshire. Its greatest length is 53 miles; its greatest breadth is 30; and the area is 705 sq. m., or 451,210 acres, nearly one-half of which is under tillage, one-fourth in pasture, and one-sixteenth in wood. Berkshire, which is one of the most beautiful of the English counties, lies in the valley of the Thames, and has an undulating surface, rising in some parts into hills. Solid chalk underlies the whole area. A range of chalk-hills, or downs, connected with the Chilterns on the east and the Marlborough Downs on the west, crosses the county into Wiltshire, from Reading to Wallingford, attaining at White Horse Hill (so called from the gigantic figure of a horse rudely defined in the chalk—a relic of ancient times) a height of 893 feet. Between this range—the west part of which is occupied by sheep-walks—and a smaller oolitic one skirting the valley of the Thames, is the Vale of the White Horse, the richest part of the county, and drained by the Ock. To the south of the Downs is the fertile Vale of Kennet, drained by the river of that name, and its feeder, the Lambourn. To the east is the forest district, comprising Windsor Forest, part of Bagshot Heath, &c. The forest chiefly consists of hazel, oak, beech, ash, and alder. The Thames skirts the whole north border of the county, winding through a course of 100 miles, but in a direct line only 52, and navigable nearly the whole way. It is the chief river of Berkshire, the other rivers of the county being its tributaries; of which the chief are the Kennet, Loddon, and Ock. The Kennet is navigable for 30 miles. The climate of Berkshire is very healthy, being mild in the valleys, and bracing on the high lands. The soil varies greatly; in the valleys it is generally a fertile loam, with a subsoil of chalk, gravel, or clay. The country between the valleys of Kennet and the White Horse consists chiefly of sheep-walks; and along the Thames, and to the west of the Ridge Way, or Downs, it is chiefly dairy and pasture land. The chief crops are oats and wheat. 'Double Gloucester' and 'pine-apple' cheese are sent in large quantities to London. Swine are extensively reared, especially near Faringdon, the breed being one of the best in England. Property is very much divided, and the number of gentlemen's seats is very great. The farms are generally of moderate size. The county is traversed by the Great Western Railway and its branch lines, and by two canals. Berkshire is divided into 20 hundreds, 151 parishes, and 12 poor-law unions. It returns five members to parliament, one for each of the three divisions (Abingdon, Newbury, Wokingham), one for Reading (the county town), and one for Windsor. Till the Seats Act of 1885, the boroughs of Wallingford and Abingdon also elected members. The county contains besides, the municipal boroughs of Newbury and Maidenhead, and the market-towns of Faringdon, Hungerford, Wantage, Wokingham, East Ilsley, and Lambourn. The chief manufactures are noticed under READING. The British and Roman remains are numerous, including Roman roads, and many camps and barrows. Of the old castles, the principal is Windsor; of monastic establishments, the abbeyes of Abingdon and Reading. The churches

are small, and from the scarcity of building-stone, are often constructed of chalk and flint. There are many Norman churches, erected in the 12th and 13th centuries. In 1836 Berkshire was transferred from the diocese of Salisbury to that of Oxford. Pop. (1801) 110,480; (1841) 161,759; (1881) 218,363; (1891) 238,446. See Lieut.-col. Cooper-King's *History of Berkshire* (1887).

Berlad (Roumanian *Bârladu*), a town of Lower Moldavia, on the Berlad River, 40 miles above its junction with the Sereth. It is an important place, connected with Braila by rail, and has a brisk trade. Pop. 20,008.

Berlen'gas, a group of rocky islands in the Atlantic Ocean, off the west coast of the Portuguese province of Estremadura.

Berlichingen, GÖTZ VON. See GÖTZ.

Berlin', the capital of Prussia, and, since 1871, of the German empire, the chief residence of the emperor of Germany, the seat of the German Reichstag and Prussian Landtag, and the third largest city of Europe, is situated on the Spree, in 52° 30' N. lat., 13° 24' E. long. The city is built upon a flat sandy plain, which, though cultivated, is far from being fertile. Its average height above the level of the Baltic is only 100 feet, and its mean temperature is 48° F. The Spree, here about 200 feet wide, with a current so sluggish as scarcely to be perceptible, flows from SE. to NW. through the city, dividing it into two nearly equal parts, and communicating with the Oder and the Baltic by canals. The inconvenience of its low-lying situation in the midst of the sandy flats of Brandenburg is more than made up for by the great geographical advantages of its position in the heart of Northern Germany, Berlin being half-way from Hamburg to Breslau, from Stettin to Leipzig, and from Memel to Alsace, as well as equidistant from the frontiers of Russia and Holland, and from the mountains of Central Germany to the Baltic. By rail it is 177 miles SE. of Hamburg, 101 NNE. of Leipzig, and 362 ENE. of Cologne; whilst from London it can be reached in 25 hours, Paris in 23½, and Vienna in 15. The advance of the city has been extraordinary. In 1804 the pop. was 182,157; in 1858 it was 438,961; in 1871 it was 826,341 (including 20,565 soldiers); in 1880, 1,122,330; and in 1885, 1,315,287, the city covering at that date an area of 15,500 acres, and measuring about 6 miles across, with a circumference of 29 miles. Pop. (1890) 1,579,224.

As far back as the 13th century, the central part of the present city was inhabited. *Kölln*, on the island formed by the Spree on its left bank, was united to *Old Berlin* on the right bank in 1307. These names are still retained by the corresponding quarters of the modern city. The Wendish *kollen* means 'a hill rising above water or swampy ground,' and *Berlin* is most probably to be traced to the root of *vechr* (English *vech* or *vecar*), 'a dam in a river.' Berlin was long little more than a fishing-village; it was not till the 'Great Elector,' Frederick-William (1640-88), had united the separate duchies of which Prussia is now formed, that the town became of consequence as the capital of a large state. In the next century it received accessions of French and Bohemian colonists, driven into exile by religious persecution. Every inducement was then held out to bring foreigners to settle in the rising city. Under Frederick the Great, it continued to prosper. At his death, the inhabitants numbered 145,000. After the peace of 1815, Berlin increased with extraordinary rapidity, and, being the seat of government, a focus of the arts and sciences, and a great centre of commercial enterprise, it has gradually risen to a position which

fairly entitles it to its present rank as the metropolis of the German empire.

The centre of the city is now devoted almost exclusively to commerce. Small towns and villages are gradually being incorporated: Moabit has already disappeared as a separate community; and Charlottenburg, a town of 42,000 inhabitants, is likely soon to follow. Berlin consists of sixteen different quarters, containing about 560 streets, 65 squares, 48 bridges, 700 public buildings, and upwards of 25,000 private houses (comprising 305,000 dwellings). The houses are built of brick, plastered or stuccoed outside, and they soon acquire a faded appearance. The style of these has very much altered since 1864. Before that, the greater portion of the houses were of one, two, or three stories, but these are fast giving way to houses of a larger size. Private houses of more than five inhabited stories and over 72 feet high have (1887) been prohibited. The increase in the value of house-property has been enormous, and the result is that about one-tenth of the population are driven to take up their abode in cellars underground, and more than 63,000 families live in dwellings of one room. In 1887 one building in Ackerstrasse housed no fewer than 1000 persons! Berlin contains a large number of very fine buildings. At the centre of the city is the royal palace, with nearly 700 apartments, including the richly adorned state-rooms, the finest of which are the magnificent 'Weisser Saal' and the palace chapel. Near this are the palaces formerly occupied by William I. and by Frederick III. as crown prince; the royal library (1,000,000 vols. and 30,000 MSS.); the old and new museums, the national gallery, the arsenal, the royal theatre, the opera-house, the guard-house, and the university. These are all situated between the Spree and the east end of the street 'Unter den Linden' (so called from its double avenue of limes), one of the finest streets in Europe, about a mile long, and almost 150 feet broad; a continuation of this, called Kaiser-Wilhelm-Strasse, beyond the Opernplatz, Lustgarten, and Kaiserwilhelmsbrücke (1887), has been cut through the old town on the other side of the Spree. The other chief streets are the Friedrichstrasse (2 miles long), the Leipzigerstrasse, the Königstrasse, and the Wilhelmstrasse, in which is the imperial chancellor's palace, where the Congress of Berlin sat in 1878. The city is adorned throughout with numerous statues of national heroes, the statue of the Great Elector (on the Langebrücke), and the equestrian statue of Frederick the Great (in front of the emperor's palace), being the most remarkable. There are more than 20 theatres in Berlin. Berlin has 35 classical and other gymnasia, 12 higher boys' and 60 higher girls' schools, and 260 middle and elementary schools, with a total of 200,000 pupils. The university, though only established in 1809, has taken a distinguished place among the universities of the world. Among its professors have been Fichte, Hegel, Schelling, Schleiermacher, the Grimms, Niebuhr, Savigny, Neander, Ranke, Curtius, Lepsius, Mommsen, and Virchow. The number of professors and lecturers is now about 380, and of students about 5600. It possesses a library of 300,000 volumes. Of other institutions may be mentioned the Academy of Sciences, by far the most important of the kind in Germany; the Military Academy; the Academy of Architecture; the Academic High School (of art); the School of Mines; the School of Agriculture; the Artillery, Technical, and Engineering Colleges; the Industrial (1881), Ethnological (1886), and other museums; the Academy of Music; the Observatory; many scientific and learned societies; several seminaries

for teachers and missionaries; and a large number of public and private institutions and societies for benevolent purposes. Of the numerous hospitals in Berlin, the Charité (adjoining which is the Pathological Institute, under Professor Virchow) is the largest in Germany. About 88 per cent. of the population are Protestants, 7 per cent. Roman Catholics, and 5 per cent. Jews. The cathedral was rebuilt in 1893-95. Of some 60 other Protestant and 10 Catholic churches, the Nicolaikirche (restored in 1880), Marienkirche (with a spire 295 feet high), and Klosterkirche, all of the 13th century, are the oldest; the Petrikirche (with a tower 315 feet high) is the loftiest; and the Michaelskirche (Catholic), Thomaskirche, Zionskirche, Dankeskirche (1884), and Heilige-Kreuzkirche (1887), are the finest and most recent. The New Synagogue (1866) has a richly decorated interior, a gilded dome 158 feet high, and seats for 3000 persons.

The Old Museum contains antiquarian specimens, a collection of 90,000 coins, a gallery of ancient sculpture, and a picture-gallery with about 1300 paintings. The New Museum contains six magnificent mural paintings by Kaulbach in the grand staircase, a very extensive and valuable collection of casts arranged in 12 saloons, the Egyptian museum, and a fine collection of engravings numbering upwards of 500,000. The National Gallery includes about 700 works by modern artists. The celebrated Brandenburg Gate (erected in imitation of the Propylæa at Athens, 65 feet high, and 205 feet wide) leads from Unter den Linden and the Pariser Platz to the Thiergarten, a park of 370 acres (with the monument of Friedrich-Wilhelm III., and those of Goethe and Queen Luise, both erected in 1880), the largest of the five parks belonging to the town. To the south-west of this lies the Zoological Garden, which has recently been considerably extended. The Botanical Garden (at Schöneberg) contains 25,000 species. Noteworthy also are the Rauch Museum in the Lagerhaus (the oldest secular building in the city), the Rathhaus, the Aquarium, the eight marble groups on the Schlossbrücke, the royal château of Monbijou (with the Hohenzollern Museum), the Ruhmeshalle in the arsenal (beautifully rebuilt in 1883), the monuments of Stein, of Calvin, of Schiller (before the royal theatre), and of the Humboldts (in front of the university), the Gothic monument on the Kreuzberg, the Column of Peace in the Belle-Alliance-Platz, the Warriors' Monument, and the Column of Victory, 200 feet high, erected in the Königsplatz in commemoration of the great victories of 1864, 1866, and 1870-71, near which are the War Office and the new building for the Reichstag (the latter, with four towers and a cupola, built in 1884-94).

The commerce and manufactures of Berlin have increased so rapidly of late years, that it now ranks among the most important mercantile places of continental Europe. The traffic is carried on by the Spree, the canals, and fourteen railways, of which the intra-mural or 'city railway,' opened in 1882, has a length of 7 miles, and passes through the middle of the city from east to west, and the suburban or 'ring railway,' 23 miles long, forms a complete circle round its outskirts. In 1886 the city railway carried eight million passengers; the city omnibuses, thirteen; and the tramway-cars, seventy. The traffic by water is 50 per cent. greater than that of any inland town of Germany, amounting in 1886 to 3,716,000 tons. The staple commodities are grain, cattle, spirits, and wool. The Exchange, daily visited by 3500 persons, is the centre of the North German money-market. The Reichsbank is the chief bank in Germany for the issue of notes. It has £6,000,000 of paid-up capital, and 218 branch offices. The principal

branches of industry are woollen-weaving, calico-printing, and the manufacture of engines and other machinery (for which there are now 100 establishments), also of iron, steel, and bronze wares, drapery goods, and confections. Of ladies' mantles alone Berlin produces annually £5,000,000 worth (two-thirds for export trade). It has also very important manufactures of railway and other carriages, sewing-machines, safes, telegraphic apparatus, scientific instruments, chronometers, steel pens, and jewellery. Of the other industries of Berlin the chief are its manufactures of pianofortes (of which the four largest manufactories turn out as many as 6000 in a year), accordions (of which Berlin is the main source of supply for the foreign trade), and other musical instruments; hardware, German silver, lamps, and metal toys; leather, paper, rubber, soap, and chemicals; furniture, carpets, porcelain, and other earthenware; gloves, linen articles, straw-hats, and artificial flowers. The silk trade alone appears to have fallen off of late years. Of beer, over 47,000,000 gallons were brewed in the year 1883-84, the malt-tax for the same period amounting to nearly £100,000. Most large enterprises are now carried on by joint-stock companies, although a number have in recent years ended in disaster, with great loss to the shareholders. In respect of its publishing trade, Berlin now shares with Leipzig the first rank amongst German cities. Berlin publishes 630 journals (some 30 daily) and magazines. Till lately the sanitary condition of Berlin was very bad; the river was polluted and open drains ran through the streets. But since 1870 the corporation has spent £10,000,000 on public health, and Berlin municipal arrangements have become a model to many other cities.

See books on Berlin by Vizetelly (London, 1879), Ring (1883), Friedel (1882), Baedeker (8th ed. 1893), and Bornmann (1892).

THE CONGRESS OF BERLIN met at Berlin in June 1878, and consisted of representatives of Russia, Turkey, Germany, Great Britain, France, Austria, and Italy. It was primarily designed to revise the preliminary treaty of San Stefano, concluded by Russia and Turkey after the war of 1877-78, and the treaty of Berlin began a new era in the history of the Ottoman empire. Roumania, Servia, and Montenegro were recognised as independent, the latter powers receiving additional territory. The concession of additional territory to Greece was recommended (and made, 1881). Roumania received the Dobruja in exchange for Bessarabia, given to Russia. Ardahan, Kars, Batoum, and other parts of Armenia were ceded to Russia by Turkey. Turkey engaged to carry out reform in Asia Minor and Crete. Bulgaria became an autonomous but tributary principality, and Eastern Roumelia (which was practically united to Bulgaria after the war with Servia in 1885), though remaining under the direct political and military authority of the sultan, secured administrative autonomy and the right to have a Christian governor-general. Bosnia and Herzegovina were to be occupied and administered by Austro-Hungary. Prince Bismarck was president of the Congress, and the Earl of Beaconsfield and the Marquis of Salisbury were the English plenipotentiaries.

Berlin, a town of Ontario, Canada, 62 miles SW. of Toronto by rail. Pop. 4054.

Berlin, the name of forty different towns, villages, hamlets, and townships in the United States, none of them of importance. The largest is a city of Green Lake county, Wisconsin, on the Fox River, 96 miles NNW. of Milwaukee by rail, with a tannery and several mills. Pop. 4241.

Berlin Decree. See CONTINENTAL SYSTEM.

Berlin Spirit, a coarse whisky made chiefly from beet-root, potatoes, &c. Because of its cheapness it has been largely used in the making of brandy, and in mixing low wines. The effect upon the consumer is pernicious, the cheap wines thus fortified being considered very unwholesome. See BRANDY, DISTILLATION, WINE.

Berlioz, HECTOR, a musical composer of remarkable but eccentric genius, was born December 11, 1803, at Côte-St-André, in the department of Isère, France, where his father was a physician. Against the wishes of his parents, who intended him to pursue the same profession, and sent him to Paris to study medicine, he devoted himself to music, entering the Conservatoire as a pupil of Lesueur. Amid severe privations—for his father had cut off his supplies—Berlioz continued his musical education, winning the second prize in 1828, and the first, or *Grand prix de Rome*, in 1830, with a cantata entitled *Sardanapalus*. In accordance with the conditions attached to this prize, Berlioz now went to Italy, where he resided for upwards of a year, and became acquainted with Liszt and Mendelssohn. The artistic surroundings of his life in Rome, however, were profoundly distasteful to him, and his sojourn was not marked by much creative work. After his return to Paris, in the year 1832, Berlioz soon brought some of his compositions to a hearing; but their complicated and peculiar nature failed to win popular recognition, and Berlioz was driven to support himself and his wife—he married the Irish actress, Henrietta Smithson, in 1833—by writing musical criticisms for various newspapers, an irksome burden from which he only freed himself at the close of his life. In this work, often wrung from him with the utmost pain and effort, are revealed those remarkable gifts of style, of picturesque expression, and of humour, which render his letters and his memoirs such admirable reading. When occasion offered, Berlioz also adopted the precarious livelihood of a concert-giver. In 1838 Paganini was so much impressed by a performance of the *Symphonic Fantastique* that he presented, or became the medium for presenting, Berlioz with the sum of 20,000 francs. In 1842 he set out on the first of those foreign concert tours which more than anything else indemnified him for the indifference of his compatriots. More than once he was offered a post in Germany, but could not make up his mind to tear himself away from Paris. In the course of these journeys Berlioz visited and was received with almost uniform enthusiasm in Belgium, Germany, Austria, Bohemia, Hungary, and even Russia. In 1848 he was engaged by Jullien as conductor at Drury Lane, but the enterprise proved a disastrous failure. In 1855 he fulfilled another engagement in London as conductor of the New Philharmonic Society. It is pleasant to think that Berlioz, who was much attached to England, and had a profound veneration for Shakespeare, has owed the posthumous rehabilitation of his fame chiefly to the efforts of musicians resident in that country. Sir Charles Hallé, a friend of Berlioz's earlier years, produced his *Dramatisation de Faust* at Manchester in 1880, since when it has made its way into the *répertoire* of all the chief choral societies of the kingdom; and Mr Manns, at the famous Saturday concerts of the Crystal Palace, has been equally assiduous in familiarising English audiences with the colossal masterpieces of the French composer. Between 1855 and 1869, in which year Berlioz died, the course of his life presents no special features. He had practically abandoned composition, the only

work produced in this period being his opera *Les Troyens*, performed with moderate success in 1863. The complete list of Berlioz's works is comprised within the limits of twenty-six *opus-numbers*; but this scanty array affords no clue to the magnitude of their dimensions. After his *Faust*, which is, perhaps, deservedly his most popular work, his most successful achievements are his symphonies, *Roméo et Juliette*, *Harold en Italie*, and the *Symphonie Fantastique*; his overtures, *Carnaval Romain*, *Benvenuto Cellini*, and *Waverley*; his charming opera, *Béatrice et Benedict*; his sacred trilogy, *L'Enfance du Christ*; and finally, his great *Messe des Morts*—the requiem written for the obsequies of General Daumont in 1837—and his *Te Deum*, in the *Jubel* of which Berlioz rises to his greatest height. A great deal of Berlioz's best literary work is buried in the files of the *Débats*; but his published writings amount to several volumes, including his *Souvenirs d'Orchestre*, *A travers Chants*, *Les Grotesques de la Musique*, his *Mémoires* (published in 1865), and finally, his well-known treatise on orchestration, which has been translated into English, and is a standard work on the subject. The characteristics of Berlioz's compositions are too remarkable to be discussed in a brief summary. His conceptions were grandiose rather than great, and in carrying them out he sometimes narrowly escaped an abrupt lapse from sublimity to bathos. He delighted overmuch in extravagantly exciting effects; but his sense of orchestration was so abnormally acute that, as an English critic has observed, no matter what the effect was, it was sure to sound exactly as he intended it. In delicate orchestral embroidery he stands alone—witness the 'Queen Mab' scherzo in his *Roméo et Juliette*, and the accompaniment to the chorus of spirits of the air in *Lelio*. Though accused of being a revolutionary in music, he entertained the most touching and enthusiastic reverence for Beethoven, Weber, and Gluck. Of an imperious and uncompromising disposition in his official and professional relations, he was nevertheless on terms of close intimacy with a great number of his contemporaries, amongst whom may be mentioned Liszt, Heine, Balzac, Stephen Heller, and Ernst. Schumann at once recognised his great talent, and published eulogistic analyses of his works in the *Neue Zeitschrift für Musik*. Berlioz was made a chevalier of the Legion of Honour in 1839, and was elected a member of the Institute at Paris in 1856. He was also librarian of the Conservatoire. The name is pronounced *Berlioz*, not *Berlioh*. See the notice by Daniel Bernard prefixed to his *Correspondence Inédite* (Paris, 1879); his *Life and Letters* (trans. by Mainwaring Dunstan, 1882); his *Autobiography* (Eng. trans. 1884); and lives by Jullien (Paris, 1885), and S. R. Thompson (1895).

Bermondsey, a south-east suburb of London, on the south bank of the 'Thames, with extensive tan-yards and wharfs.

Bermudas, or **SOMERS' ISLANDS**, British possessions in Mid-Atlantic, were so named respectively from Bermudes, a Spaniard, who first sighted them in 1515, and from Sir George Somers, an Englishman, whose shipwreck here in 1609 was the immediate occasion of their being colonised from Virginia—itsself only four years old—in 1611. This low and lonely archipelago is a mere group of specks; for though it numbers perhaps 100 islets and more than twice that number of rocks, yet it measures only about 12,000 acres in all, the whole occupying a space of about 14 miles in length by little more than 5 in breadth. The islands are composed of blown coral sand, and are surrounded by a living, growing reef of coral, the whole being

a modified Atoll (q.v.), and the most northerly of such structures. The great value of this natural fortress as a British naval station, defended by its extensive barrier of reefs and rocks, with only one or two intricate channels, arises from its situation. In 32° 15' N. lat., and 64° 51' W. long., the Bermudas occupy, commercially and politically, a singularly commanding position. At a distance of 580 miles from Cape Hatteras, in North Carolina, they are about equally remote from the north of Maine and from the south of Florida; while they are a connecting link between Canada and the British West Indies. In the principal or Main Island is situated the present seat of government, Hamilton, on a deep inlet running 2 or 3 miles into the land. St George's, the island next in importance, contains the picturesque town of the same name, and a land-locked harbour, the entrance to which is defended by strong batteries. Ireland

Island is entirely occupied by Her Majesty's Dockyard and other naval establishments; and Boaz and Watford Islands have the military depôts and garrisons. At Ireland Island also is the celebrated Bermuda Floating Dock, built in England, and towed out in 1869. It is 381 feet in length by 124 feet in breadth, and is sufficiently powerful to lift a ship of the *Minotaur* class. The minor islands of St David, Cooper, Smith, Nonsuch, Godet, and others, form numerous picturesque creeks and bays of great size and depth, such as the Great Sound, Castle Harbour, Harrington Sound, and others. Most of the other islands are insignificant, many of them without name or inhabitant. The group forms an almost continuous chain, and, with one break, there is uninterrupted communication by roads, causeways, and bridges for a distance of about 22 miles; but from the strange shapes of most of the islands, and the number of spacious lagoons, the communications are almost as necessarily by water as are those of Venice. The climate is tempered by an almost constant sea-breeze, and the air is moist at all seasons. The thermometer never falls below 40° F., and seldom rises above 85°. The islands are becoming a popular holiday and winter resort, especially for Americans, and both Hamilton and St George's are plentifully supplied with hotels and shops. The climate, however, is not suited for consumptive invalids. The soil is poor in quality, and not more than a fourth is cultivable at all; but there being no winter frosts, crops can be prepared for March, April, May, or June, and the large quantities of early potatoes, onions, tomatoes, and other garden vegetables, which in these months fetch high prices at the New York markets, enable the Bermudians to live comfortably on the income of their comparatively small portions of ground.

Besides being useful as a station for those British vessels of war which are charged with the care of the West Indies on the one side and the northern provinces on the other, Bermuda was formerly an important dépôt for convicts, but since the year 1862 it has ceased to be so. There is a regular fortnightly mail service with New York, and a weekly service in the early spring. The colony has no railways, but has a very complete telegraph system. Pop. (1871) 12,121; (1881) 14,314, including 5384 whites, 8564 coloured persons, and 266 civilians in the naval and military establishments; (1891) 15,013. The exports vary from £65,000 to £140,000 a year; the imports from £270,000 to £330,000. The revenue, over £30,000, covers the expenditure; the debt is £10,000. The fisheries are productive. As their own early crops are too valuable for home consumption, the Bermudians import grain, flour, rice, and also livestock from the United States. The group is under the authority of a governor and council of 9 members appointed by the crown; and an assembly of 36, four of whom are elected by each of the nine parishes. Hamilton and St George's have each a mayor, three aldermen, and five councillors. The schools are mostly private, and charge fees, but are aided by public grants, under the supervision of a Board of Education. In September 1899 an unusually severe cyclone visited the 'still vexed Bermoothes'—of which Bermuda is now the accepted spelling. More than two-thirds of the population belong to the Church of England, which has five clergymen, under the Bishop of Newfoundland and Bermuda; the Presbyterians have two, the Wesleyans three ministers, and other bodies are also represented. Under a temporary act, all churches are endowed at the rate of £10 for every 100 members. See works on Bermuda by Lefroy (1882), Ogilvy (1883), Dorr (New York, 1884), Stark (Boston, 1884), and Heilprin (Phila. 1890); and the *Annual Bermuda Pocket Almanac, Guide, and Directory*.

Bermudez, a state in the NE. of Venezuela, between the Orinoco and the Caribbean Sea, formed in 1881 from the former states and present sections of Barcelona, Cumana, and Maturin. Area, 32,128 sq. m.; pop. 300,597.

Bern, or **BERNE**, a Swiss canton, bounded on the N. by France. It is the most populous, and next to the Grisons the most extensive canton of Switzerland; its area being nearly 2650 sq. m., and its population (1898) 549,387—more than one-sixth of the Swiss people. Of these, 66,000 were Roman Catholics and over 1300 Jews. The fertile valleys of the Aar and the Emment divide the mountainous Alpine region in the south from the Jura Mountains in the north. The Bernese Oberland, or Highlands, comprises the peaks of the Jungfrau, Mönch, Eiger, Schreckhorn, Finsteraarhorn, &c., and the valleys of Hasli, Lauterbrunnen, &c. The lakes of Thun, Brienz, Neuchâtel, and Biemme are in the canton, which is watered by the Aar and its several tributaries. The climate is generally healthy. The plains of the Aar and the Emment are the most fruitful, producing corn and fruits of various kinds, and affording excellent pasturage for cattle, which, with dairy-produce, form the chief agricultural wealth of Bern. The vine grows in some districts. The horses of the Emmenthal are much prized. The lakes abound with salmon and trout. Iron-mines are worked, and a little gold is found, and quarries of sandstone, granite, and marble are abundant. Its manufactures, which are not extensive, consist chiefly of linen, coarse woollens, leather, iron, and copper wares, articles of wood, and watches. Bern entered the Swiss Confederation, in which it now holds the second rank, in 1352. In the 15th and 16th centuries, it

added to its possessions Aargau and Vand, which it lost during the wars of the first Napoleon; but it received in return Biemme and its territory, and the greater part of the bishopric of Basel. The present constitution of the canton, proclaimed in 1874, but based on the laws of 1848, is one of representative democracy.

Bern, or **BERNE**, capital of the above canton and of Switzerland, is situated on a lofty sandstone promontory formed by the winding Aar, which surrounds it on three sides, and is crossed by several bridges, one of which is an imposing iron structure of 1883, 751 feet long, and 115 high. Bern is 68 miles by rail SSW. of Basel. It is one of the best and most regularly built towns in Europe, as it is the finest in Switzerland. The houses are massive structures of freestone, resting upon arcades, which are lined with shops, and furnish covered walks on both sides of the street. Rills of water flow through the streets. The view of the Alpine peaks from the city is magnificent. The principal public buildings are a Gothic cathedral (1421-1573), whose restoration and completion was undertaken in 1887; the magnificent Federal Council Hall (1857), the mint, the hospital, and the university. Bern has an interesting museum, and a valuable public library of 50,000 volumes. The manufacturing industry is trifling, and consists chiefly of dress fabrics and hats; but it has a considerable trade in the produce of the surrounding district. Pop. (1893) 47,620. Bern was founded in 1191, was made a free imperial city in 1218, under Frederick II., and gradually extended its possessions until it became an independent state; and between 1288 and 1339 successfully resisted the attacks of Rudolf of Hapsburg, Albert his son, and Louis of Bavaria. The 'Disputation of Bern' between Catholics and Reformers in 1528 (January 6-27) prepared the way for the acceptance of the reformed doctrine. Bern is the residence of foreign ministers, and, since 1849, the permanent seat of the Swiss government and diet. On account of the traditional derivation of its name (old Swabian *bern*, 'a bear'), bears have for several centuries been maintained in Bern at the expense of the community, and the bear-pit is still one of the 'sights' of the city.

Bernadotte, the French Napoleonic officer who became king of Sweden as Charles XIV. (q.v.).

Bernalda, a town in South Italy, in the province of Potenza. Pop. 6976.

Bernard, **GREAT ST.** See **ST BERNARD**.

Bernard, **CLAUDE**, a great French physiologist, born at Saint-Julien, near Villefranche, 12th July 1813. He studied medicine at Paris, became a hospital-surgeon in 1839, and two years later assistant at the Collège de France to the great physiologist Magendie, with whom he worked for thirteen years, until his own appointment in February 1854 to the chair of General Physiology. The same year he was chosen member of the Academy of Sciences, and in 1855 he succeeded to Magendie's chair of Experimental Physiology. Bernard was elected to the Academy in 1869, and died at Paris, February 10, 1878. His funeral was conducted at the public expense, an honour never before given to a man of science, and his *loge* at the Academy fell to Renan. As an original investigator, Bernard stands among the foremost of the century. His earliest researches were devoted to the physiological action of the various secretions of the alimentary canal. His proof that the sole use of the pancreatic juice in the digestive system is so to modify the ingested fats as to render them capable of being absorbed by the chyle ducts, is a masterpiece of biological demonstration. Another important discovery established the saccharine function of the

liver. Still more important was his demonstration of the connection between this function of the liver and the nervous system. He showed that the normal formation of sugar in the liver could be totally interrupted by severing the pneumogastric nerve in the neighbourhood of the heart, and moreover, that by a wound made on the floor of the fourth ventricle of the brain, an abnormal formation of sugar could be immediately induced—a great contribution to our knowledge of the pathology of diabetes. For these great discoveries Bernard received the physiological prizes of the French Academy in 1851 and in 1853. Later researches were on the change of temperature of the blood in its passage from one organ to another; on the absorption of oxygen by the blood, and the respective amount of it in arterial and in red and black venous blood; on the comparative properties of the opium alkaloids; on the poisonous properties of curarine; and on the sympathetic nerves in general; as well as numerous investigations on the individual processes in the act of digestion. The great experimentalist was a remarkably lucid lecturer, alike in the academic chair and on the platform, and his *Leçons de Physiologie Expérimentale appliquée à la Médecine* (1865) is a standard work far beyond his country. Other books are: *Leçons sur les Effets des Substances Toniques et Médicamenteuses* (1857), *Introduction à l'Étude de la Médecine Expérimentale* (1865), and *Leçons de Pathologie Expérimentale* (1874). Many of his papers appear in the special scientific journals, and in the *comptes rendus* of the Académie des Sciences and the Société de Biologie, of which last he was a founder and president. See the Life by Sir Michael Foster (1899).

Bernard, ST, of Clairvaux, one of the most influential theologians of the middle ages, was born of a noble family at Fontaines, near Dijon, in Burgundy, in 1091; entered the Cistercian monastery of Cîteaux at twenty-two; and became two years later the first abbot of the newly-founded monastery of Clairvaux, in Champagne. He died at Clairvaux, August 20, 1153; and was canonised by Pope Alexander III. in 1174. His ascetic life, solitary studies, and stirring eloquence made him during his lifetime the oracle of Christendom. He founded more than seventy monasteries, and his persuasive earnestness was such that he drew also into the monastic life both his two elder and his two younger brothers, while we are told that mothers hid their sons, wives their husbands, companions their friends, that they might escape the restless spell of his spiritual enthusiasm. He was honoured with the title of the 'mellifluous doctor,' and he is regarded by the Catholic church as the last of the fathers. Bernard drew up the statutes of the Knights Templars at the request of their grandmaster in 1128. The reverence in which he was held gave him great influence in the political movements of his time. It was due to his persuasion that Innocent II. was recognised at the Synod of Etampes (1131) by Louis VI. of France, soon after by Henry I. of England and the Emperor Lothar of Germany, as pope in opposition to the antipope Anacletus. His influence in Christendom rose to its height under the reign of Pope Eugenius III., his disciple. It was his glowing eloquence at the council at Vézelay in 1146 that kindled the enthusiasm of France for the second crusade. Charged by the pope to excite the religious zeal of the people of France and Germany, Bernard accomplished his mission with fatally memorable success. Fields, towns, cities, and castles were in many places almost depopulated, and thousands of men, fired by his prophetic eloquence, hurried to the East, but few of whom were ever to see their homes again.

The influence of St Bernard as a spiritual teacher through his fervid piety and living grasp of Christian doctrine was a wholesome antidote to the dry and cold scholasticism which prevailed among the churchmen of his age. 'If there ever lived on the earth a God-fearing and holy monk,' says Luther, 'it was St Bernard of Clairvaux.' Yet his Christianity lacked the perfect flower of gentleness, and his harsh severity towards the unhappy Abelard and Bishop Gilbert of Poitiers is a distinct blot on his character. His writings are exceedingly numerous. They consist of more than 400 epistles, 340 sermons, and 12 distinct theological treatises. They are all instinct with genius, though it is difficult for us now to appreciate their extraordinary influence. The best edition of the works of St Bernard is that of Mabillon, first printed at Paris in 6 vols. (1667-90). They appear as 4 vols. of Migne's *Patrologia Latina* (1851-52). He was one of the greatest of the Latin hymn-writers, many modern hymns being based on his *Jesu Dulcis Memoria*. The monks of the reformed branch of the Cistercians, which he instituted, are often called, after him, Bernardines. He gave name also in France to the nuns of the Cistercian order, which his sister, St Humbeline, is said to have founded. See Morison, *Life and Times of St Bernard* (3d ed. 1877) and lives by Ratisbonne (9th ed. Paris, 1883); J. Mabillon (1889; Eng. trans. by Eales), and R. S. Storrs (1893).

Bernard of Morlaix, a monk of Cluny about 1140, is said to have been born of English parents at Morlaix in Brittany. He is the author of the remarkable poem *De Contemptu Mundi*, in 3000 long rolling, 'leonine-dactylic' verses, which has been freely translated by Dr Neale as *The Rhythm of Bernard of Morlaix*. From this 'Jerusalem the Golden' and other well-known hymns are taken.

Bernard Dog. See ST BERNARD DOG.

Bernardines. See CISTERCIANS.

Bernardino, ST, of Siena, born in 1380 at Massa-Carrara, of a distinguished family, made himself famous by his rigid restoration of their primitive rule amongst the degenerate order of the Franciscans, of which he became a member in 1404. In 1438 he was appointed vicar-general of his order for Italy. Bernardino was unweariedly devoted in his activity during the great Italian plague of 1400, both as an impressive preacher and an attendant upon the sick and dying. He founded the *Frates de Observantia*, a branch of the Franciscan order, which already numbered more than 300 monasteries in Italy during his day. Bernardino died in 1444, and was canonised in 1450. His eminently mystical works were published at Venice in 1591, and at Paris in 1636.

Bernauer, AGNES, the beautiful daughter of a poor surgeon of Augsburg, secretly married, in 1432, to Duke Albrecht of Bavaria, only son of the reigning Duke Ernst. Their happiness was undisturbed, till Albrecht's father, becoming aware of his son's attachment, had the knightly lists shut against him, as one who was living with a woman in licentiousness. Albrecht now made Agnes be openly honoured as Duchess of Bavaria. But in her husband's absence, Duke Ernst had Agnes tried for sorcery, condemned for having bewitched Albrecht, and drowned in the Danube in the presence of the whole people, October 12, 1435. Albrecht took up arms against his father; but after a year of war he was prevailed on to return to his father's court, and ultimately consented to marry Anna of Brunswick.

Bernay, a French town in the department of Eure, 25 miles WNW. of Evreux. One of the

largest horse-fairs in France is held here annually. Pop. 6931.

Bernays. JAKOB, an eminent philologist, born of Jewish parents at Hamburg in 1824, made his studies at Bonn, where he became professor and librarian in 1866, and died, May 26, 1881. Among his numerous books were a *Life of Scaliger* (1855), *Lucian und die Cyniker* (1879), an edition of *Lucretius* (1852), and a translation of three books of Aristotle's *Politics* (1872). His *Gesammelte Abhandlungen* were edited by Usener (1885).

Bernburg. a town in the German duchy of Anhalt, till 1863 capital of Anhalt-Bernburg, lies on the Saale, 23 miles S. of Magdeburg. Bernburg has manufactures of machinery, sugar, spirits, porcelain, paper, and starch. Pop. (1890) 28,326.

Berne. See BERN.

Berners. or BARNES, DAME JULIANA, a writer on hunting and hawking, of whom almost nothing is really known. Tradition has it that she was prioress of Sopwell Nunnery, near St Albans, and daughter of Sir James Berners, who was beheaded in 1388. To her has been generally conceded the authorship of the *Treatyse persegynge to Hawkyngge, Huntynge, and Fysshynge with an Angle*; also a right noble *Treatyse on the Lynage of Cote Armiris; codyng with a Treatyse which specifyeth of Blasynge of Armys*; although she probably wrote only the treatise on hunting, and part of that on hawking. The heraldry is certainly not hers. The earliest extant edition, printed at St Albans in 1486, is issued without the treatise on fishing. A facsimile of this with an introduction by William Blades appeared in 1881. A folio edition was printed by Wynkyn de Worde in 1496, and at least ten more editions appeared before 1600, a testimony to the popularity of the 'Boke of St Albans'. A facsimile was issued by Haslewood in 1810, discussing how far she was the first woman-writer in English. An edition of the *Fysshynge* was printed by Baskerville in 1827, and another in 1880. —For Lord Berners, see FROISSART.

Bernese Oberland. See BERN.

Bernhard. Duke of Weimar, a celebrated German general, born in 1604, was the youngest of the eight sons of John, third Duke of Saxe-Weimar. On the outbreak of the 'Thirty Years' War, he took the side of Protestantism, and first distinguished himself in 1622 at the bloody battle of Wimpfen. Subsequently, he became colonel in the army of Christian IV. of Denmark. In 1631 Gustavus Adolphus made his appearance in Germany, and Bernhard was one of the first who flew to his standard. He commanded the left wing at Lützen, and after the king's death had the chief command. He took a very important part in the war; but after a brilliant career, he fell suddenly ill, and died at Neuburg on the Rhine, July 8, 1639. Bernhard's own opinion, and that of others, that he died of poison administered by his physician, who is supposed to have been in the pay of Richelieu, is not supported by evidence. See Droysen, *Bernhard von Weimar* (Leip. 1885).

Bernhardt. ROSINE, called SARAH, a French actress, born of Jewish parents in Paris, October 22, 1814, was baptised into the Christian faith by her father's desire, and brought up in a convent at Versailles. Entering the Paris Conservatoire in 1858, she gained second prizes for both tragedy and comedy, and in 1862 made her début as 'Iphigenie' at the Théâtre Français, but attracted so little notice that she soon left the theatre, only to meet with still less success in burlesque at the Gymnase and Porte St Martin. In 1867 she played minor parts at the Odéon, and became famous by her impersonation of the 'Queen of Spain' in *Ruy Blas*,

and of 'Zanetto' in Coppée's *Passant*. She was recalled to the Théâtre Français in 1872, and after 1879 made annual appearances, with marked success, in London. Her tours in North and South America, in Italy, Russia, &c., were also pecuniarily successful; but her essay at the management of a Paris theatre involved her in heavy debt. In 1882 she was married to M. Jacques Daria or d'Amala, a Greek actor, from whom she was divorced shortly afterwards. Madame Bernhardt is probably the greatest *tragédienne* since Rachel, and in comedy also she ranks as a finished actress. Her talent as an artist is considerable, and both paintings and statues from her studio have appeared in the Salon.

Bernhardy. GOTTFRIED, a German scholar, born of Jewish parents near Frankfurt in 1800, was educated at Berlin, and in 1829 became director of the philological seminary at Halle. Here he died, May 14, 1875. Of his numerous philological works may be mentioned his *Syntax der griechischen Sprache* (1829); *Paralipomena Syntaxis Græcæ* (1854); and the critical edition of *Suidæ Lexicon* (4 vols. 1834-53). His works on Roman and Greek literature, especially the history of the latter, are also of high value.

Berni (also *Bernia*), FRANCESCO, a favourite Italian poet, from whom comic or jocular poetry has the name of *Versi Berneschi*, was born at Lamporecchio, in Tuscany, about 1496. He first entered the service of his uncle, Cardinal Bibbiena, and was afterwards for several years secretary to Ghiberti, chancellor to Clement VII. About 1530 he betook himself to Florence, where he was made a canon, and lived in favour with the two Medici, Duke Alessandro, and Cardinal Ippolito, till his death in 1536, which, however, according to another story, was brought about by the former, in consequence of Berni's refusal to poison the cardinal. His *Opere Burlesche* are to be found in the *Classici Italiani* (Milan, 1806). His recast or rifacimento of Boiardo's *Orlando Innamorato* was received with such favour that it was thrice reprinted from 1541-45; it is still read in Italy (and justly so) in preference to the original. He had a large share in establishing Italian as a literary language. A full account of Berni is given in his *Life* (Florence, 1882) by Virgili, who has also published a volume of his lyrics, letters, and Latin verses (1885).

Bernicia, a Latinised form of the British word *Bryneich*, used to indicate the northern part of what became the kingdom of Northumbria, the part north of the Tees. The Anglian kingdom of Bernicia is said to have been founded by Ida, who made his capital at Bamborough about 550 A.D. See NORTHUMBRIA.

Bernier. FRANÇOIS, a French physician and traveller, famous alike as a philosopher and a wit, was born at Angers, in France, and departed for the East about 1654. He visited Syria, Egypt, Arabia, and India, in the last of which countries he resided for twelve years in the capacity of physician to Aurungzebe, and on his return to France he published a delightful account of his travels in 1670-71. Bernier died at Paris in 1688.

Bernina, a mountain of the Rhaetian Alps, 13,290 feet high, in the Swiss canton of Grisons, with remarkable and extensive glaciers. Its summit was first attained in 1850. The Bernina Pass, which attains an elevation of 7642 feet, and over which a carriage-road was completed in 1864, leads from Pontresina to Poschiavo.

Bernini. GIOVANNI LORENZO, sculptor, architect, and painter, was born at Naples in 1598. He early devoted himself to sculpture, and in his

eighteenth year finished his admired group of Apollo and Daphne, which gave promise of greater excellence than was afterwards realised by the artist. Pope Urban VIII. employed him to produce designs for the embellishment of St Peter's at Rome, and his greatest achievement in architecture is its colossal colonnade. In 1663 he accepted the flattering invitation of Louis XIV., and travelled to Paris with great pomp. In Paris he resided above eight months; but his design for the Louvre being deemed inferior to Perrault's, he confined himself entirely to sculpture. His visit, however, proved a highly remunerative one. Richly laden with gifts, he returned to Rome, where he died, November 28, 1680, leaving a fortune of £100,000 to his children. Besides his works in sculpture, Bernini also left numerous paintings behind him. Few artists have been so much admired and rewarded during their lifetime as Bernini; but time has rather subtracted from than added to his fame.

Bernoulli, or **BERNOULLI**, was the name of a family that produced a succession of men who became famous over all Europe for the successful cultivation and extension of various branches of mathematical and physical science. The family originally resided in Antwerp, whence, in 1583, its attachment to the reformed religion drove it to seek an asylum in Frankfort. Afterwards the Bernoullis settled in Basel, where they achieved the highest professional honours. Eight of them became highly distinguished; but special mention can be made here only of the three most celebrated—James, John, and Daniel.

JAMES BERNOULLI was born at Basel, December 27, 1654, where he also died, August 16, 1705. He devoted his life to the study of mathematics, of which, in 1687, he became professor in the university of Basel, succeeding in that chair the distinguished Megerlin. His *Commentarii Novi Systematis Cometae*, an essay on comets, suggested by the appearance of the comet of 1680, and his essay *De Gradibus Ætheris*, both showed the influence of Descartes' philosophy. Besides a variety of memoirs on scientific subjects, he published no other work of importance. *De Arte Conjectandi* was a posthumous work concerning the extension of the doctrine of probabilities to moral, political, and economical subjects. His collected works were published in 2 vols. 4to, at Geneva, in 1744. Among his triumphs are to be recorded his solution of Leibnitz's problem of the isochronous curve, and his determination of the catenary. At his request, a logarithmic spiral was engraved on his tomb, with the motto, *Eadem mutata resurgo*.

JOHN BERNOULLI, brother of the preceding, was born at Basel, July 27, 1667. He and James were the first two foreigners honoured by being elected associates of the Academy of Sciences at Paris, and they were also made members of the Academy of Berlin. John devoted himself to chemical as well as to mathematical science. In 1694 he took the degree of M.D., and soon after became professor of Mathematics at Groningen, whence he only removed to succeed his brother James in the university of Basel. His forte was pure mathematics, in which he had no superior in Europe in his day. He died January 1, 1748. The determination of the 'line of swiftest descent,' and the invention of the 'exponential calculus,' have been claimed as his achievements. His collected works were published at Geneva, in 4 vols. (1742).

DANIEL BERNOULLI, born at Groningen, February 9, 1700, died at Basel, March 17, 1782, was the second son of John. Like his father, he devoted himself to medicine as well as to mathematics. The family reputation early helped him to the professorship of Mathematics at St Petersburg,

which he held for several years. Thence, however, he ultimately retired to Basel, much against the will of the czar. At Basel, he occupied in succession the chairs of Anatomy and Botany, and of Experimental and Speculative Philosophy. He published various works between 1730 and 1756, of which the chief are concerned with pneumatical and hydrodynamical subjects.

Berœ, one of the commonest representatives of the most intensely active sub-class of Cœlenterates—the Ctenophora (q.v.). These are free-swimming pelagic animals, of great delicacy and beauty, generally of a more or less cylindrical form, and without any trace of skeleton, which indeed rarely occurs in the more active lower animals. Berœ is the type of a small family, Berœidae, in which the body is oval or spherical, but slightly flattened in one plane. They are transparent, and often beautifully coloured, especially during reproductive periods. The lower pole is occupied by the large mouth, which leads into a spacious and complex alimentary canal ending at the top. The superior pole bears a complex sensory organ, and between the two are eight meridian bands, each bearing a row of comb-like plates formed from the union of cilia. These ciliary plates move very rapidly, producing a beautiful iridescence, and wafting the berœe through the water in any desired direction. It has been recently shown that the limy 'otocyst,' which forms part of the sense organ, may act as an automatic balancing and steering apparatus. Like many other active marine animals, the Ctenophora are phosphorescent, and berœe is one of the most brilliant examples. The light shines out especially from the regions of the meridional bands. The berœes are very voracious, feeding on small crustaceans and the like, but with a marked preference for their own relatives. They are themselves swallowed in shoals by whales. During the day they descend to deeper water, but come to the surface at night. In autumn they seem to frequent the surface more constantly, and may then be observed in great crowds. The distribution of the genus, which includes three certain species, is very wide, and one form is quite common on British coasts. Berœe differs most markedly from related forms, such as Cydippe, Pleurobrachia, &c., in the absence of a pair of long tentacles. See CTENOPHORA.

Bero'sus, a priest of Babylon, who had a knowledge of the Greek language, and flourished about 260 B.C. He wrote, in Greek, three books of Babylonian-Chaldean history, in which he made use of the archives in the temple of Bel at Babylon. The work was highly esteemed by Greek and Roman historians, but unfortunately only a few fragments have been preserved by Josephus, Eusebius, and Syncellus; even these are of great value, as they relate to the most obscure portions of Asiatic history. They have been edited by W. Richter (Leip. 1825), and Müller, in the second volume of *Historiæ Græcorum Fragmenta* of the 'Collection Didot' (Paris, 1848). The *Antiquitatum Libri Quinque cum Commentariis Joannis Annii*, first published in Latin by Eucherius Silber (Rome, 1498) as a work of Berosus, and often republished, was the pseudonymous work of the Dominican, Giovanni Nanni of Viterbo. See BABYLONIA.

Berre, **ÉTANG DE**, an extensive lagoon of France, department Bouches-du-Rhône, about 45 miles in circumference, with large salt-works and eel-fisheries.

Berri, or **BERRY**, formerly a province of Central France, now forming the departments of Indre and Cher. Having come, in 1100, into the possession of the French crown, it was raised to a duchy in 1360, and gave title at various times to French

princes, the younger son of Charles X. being the last who held it.

Berri. CHARLES FERDINAND, DUC DE, second son of the Count of Artois (afterwards Charles X.), was born at Versailles, January 24, 1778. In 1792 he fled with his father to Turin; fought with him under Condé against France; afterwards visited Russia, and lived for some time in London and Edinburgh. In 1814 he returned to France, and the following year was appointed by Louis XVIII. commander of the troops in and around Paris. In 1816 he married Caroline Ferdinande Louise (born 1798), eldest daughter of Francis, afterwards king of the Two Sicilies—a marriage on which depended the continuance of the elder Bourbon line. The duke was assassinated on 13th February 1820, as he was conducting his wife from the Opera-house to her carriage, by a fanatic named Louvel. He left only a daughter, born 1819; but on 29th September 1820, the widowed duchess gave birth to the Comte de Chambord (q.v.). After the July revolution, 1830, in which the duchess exhibited immense force of character and courage, offering herself to lead on the troops against the insurgents, she, with her son, followed Charles X. to Holyrood, but left a considerable party in France in favour of the pretensions of her son as Henry V. During a visit to Italy, she was so far encouraged in her ambition, that a project was formed for reinstating the Bourbons; and, accompanied by several friends, she landed near Marseilles, April 29, 1832. After many adventures, she was betrayed by a Jew at Nantes, and was imprisoned in the citadel of Blaye. The confession of the duchess, that she had formed a second marriage with the Neapolitan marquis, Lucchesi-Palli, at once destroyed her political importance, and the government set her at liberty. She died in Styria, 16th April 1870.

See works by Ménière (1882) and Imbert de St Amand (1890; trans. 1893).

Berry (*Bacca*), a term employed in popular language to designate almost any small succulent fruit, but restricted in botanical language to simple fruits with pericarp succulent throughout, whether developed from superior (grape, potato, bitternut, belladonna, bryony, asparagus, tomato), or more commonly inferior ovary (gooseberry, currant, hawberry, bilberry, &c.). Strawberry, raspberry, blackberry, mulberry, yewberry, &c. are thus all excluded from the definition, for the first is an expanded succulent axis, bearing the true fruits as dry nutlets; and the second and third are an aggregation or *aterio* of drupes (corresponding in fact, save for their origin from a single flower, to a bunch of cherries). The mulberry arises from the union of a crowded cluster of separate female flowers of which the fruit of each is an achene, the pulp belonging to the calyx, while the red berry-like pulp of the yew fruit is a subsequent upgrowth or *Aril* (q.v.).—The orange and other fruits of the same family, having a thick rind dotted with numerous oil-glands, and quite distinct from the pulp of the fruit, receives the name *hesperidium*; the fruit of the pomegranate, which is very peculiar in the manner of its division into cells, is also sometimes distinguished from berries of the ordinary structure by the name *balansta* (see POMEGRANATE). Fruits which, like that of the water-lily, are at first juicy, and afterwards, when ripe, are dry, are sometimes designated *berry-capsules*. Fruits of the gourd family (*Cucurbitaceæ*) are commonly distinguished under the name of *pepo*, but, at anyrate when the rind as well as the pulp is soft at maturity, are true berries.

Berryer. PIERRE ANTOINE, a distinguished French advocate and political orator, was born in Paris, 4th January 1790, and first distinguished

himself by his brilliant defence of Lammennais in 1826, and Châteaubriand in 1833. In 1829 he was chosen deputy, and ever afterwards steadily represented the rights and policy of the elder Bourbons. His legitimist tendencies kept him for a time in the political background under Louis-Philippe; but as the legitimist party in the Chamber increased, his position grew in importance. He repeatedly undertook the defence of persons prosecuted by the government, not only of his own party, but republican leaders. It was he who defended Louis Napoleon, 1840, after the Boulogne escapade, as well as Montalembert afterwards in 1858. With the elder Bourbons he was in constant communication, and was one of the heads of the legitimist party who made a pilgrimage to the Count of Chambord in London in 1843. After the revolution of 1848, he represented the Bouches-du-Rhône; seemed inclined to support the government of the president, Louis Napoleon; and became a member of his privy-council. But this did not hinder him from going to Wiesbaden in 1850 to do homage to the Count of Chambord. He was one of the few who boldly protested against the *coup d'état*. In 1854 he was elected a member of the French Academy. His inaugural speech contained some uncomplimentary allusions to the emperor, and its publication was for a time prohibited. He died at his country seat near Paris, 29th November 1868. His *Discours Parlementaires* fill 5 vols. (1872-74); his *Plaidoyers*, 4 vols. (1875-78). His statue was erected in the Palace of Justice at Paris in 1879.

Bersaglieri (Ital., 'marksmen'), the riflemen or sharpshooters of the Italian army, first organised in the Sardinian army in 1836. Light active soldiers, wearing a picturesque but serviceable dark-green uniform, and hats with dark plumes of cock's feathers, they have always been to the front, alike in the Crimea and in the struggles that resulted in Italian unity. There are over 46,000 bersaglieri in the regular army. Akin to them are the Alpini, a force of mountaineer sharpshooters, organised since 1876.

Ber-serker, a redoubtable hero in Scandinavian mythology, the grandson of the eight-handed Starkadder and the beautiful Alfhilde. By the daughter of King Swafurum, whom he had slain in battle, he had twelve sons, who inherited the name of Berserker, along with his frenzied, warlike fury or 'berserker-rage.' The name means 'bear-sark' (or shirt), not 'bare shirt,' and by Baring Gould is connected with the Werewolf (q.v.) superstition.

Bert, PAUL, French statesman and physiologist, was born at Auxerre in 1833. He studied both law and medicine, became assistant to Claude Bernard at the College of France, and successively occupied the chairs of Physiology at Bordeaux and Paris. Entering political life in 1870, on the proclamation of the Republic, he was four times re-elected to the Chamber. He brought forward laws removing primary instruction from the control of the religious orders, and making it compulsory. During the premiership of Gambetta he held the post of minister of public instruction and worship. While engaged in public life, M. Bert still pursued with ardour his scientific investigations, attracting world-wide attention by his experiments in vivisection. Appointed by the French Ministry to the governorship of Tonquin and Annam, he went out there in 1886, but died on 11th November of the same year. The anti-religious views of M. Bert excited much controversy. He was also the author of several works on anatomy and physiology, and of numerous educational and political writings. M.

Bert was a member of the French Academy of Sciences, and of many other distinguished bodies at home and abroad.

Bertha, the name of several famous women in the legendary history of the middle ages.—ST BERTHA, whose day is kept on the 4th July, a Frankish princess who married Æthelbert, king of Kent (560 A.D.), became the means of his conversion, and of the spread of Christianity among the Anglo-Saxons.—In the romances of the Charlemagne cycle, there figures a BERTHA, called also 'Bertrada with the Big Foot,' daughter of Count Charibert of Laon, wife of Pepin the Little, and mother of Charlemagne. Her whole personality is of a mythical nature, and has several of the attributes of the goddess Berchta.—In the romances of the *Round Table*, the name of a sister of Charlemagne, mother of Roland by Milo d'Anglesis.—Better known is BERTHA, wife of Rudolf II. (937), king of Burgundy beyond Jura, who afterwards married Hugo, king of Italy.

Berthelot, PIERRE EUGÈNE MARCELLIN, an eminent French chemist, born at Paris, October 25, 1827, at an early age made a special study of acids and fermentation, and was appointed professor of Organic Chemistry in the École de Pharmacie in 1859, and in the Collège de France in 1865. In 1876 he was named inspector-general of education, in 1886-87 he was minister of public instruction, and in 1895 foreign minister. His labours to reproduce the substances which enter into the composition of organic bodies, besides opening up a new field of research, have directly benefited more than one industry. His early studies established the theory of polyatomic alcohols (see ALCOHOL), and he has devoted much attention to explosives; whilst, more recently, his observations of the heat-phenomena which produce chemical combinations have laid the foundation of thermochemistry.

Among his works are *Chimie Organique* (1860), *La Poudre et les Matières Explosives* (1872), *La Synthèse Chimique* (3d ed. 1881), *Mécanique Chimique* (1879), *Les Origines de l'Alchimie* (1885), *Science et Philosophie* (1886), and *Science et Religion* (1897). And see the *Correspondance* between him and Renan (1898).

Berthier, ALEXANDRE, Prince of Neuchâtel and Wagram, was born at Versailles, February 20, 1753. A soldier's son, he entered the army in 1770, and fought with Lafayette in the American war of independence. In the French Revolution he soon rose to be chief of the staff in the army of Italy (1795), and in 1798 entered the papal territory, and proclaimed the republic in Rome. He accompanied Napoleon to Egypt in the same year as chief of the staff, a post which he also held in all the subsequent campaigns. At the revolution of 18th Brumaire (1799), he became war-minister, but continued to accompany the emperor on his campaigns. In 1807 he was made sovereign of the formerly Prussian principality of Neuchâtel, vice-constable, and imperial prince. In the campaigns of 1812, 1813, and 1814, he was constantly by the emperor's side, and acted both as chief of the staff and as quartermaster-general. On the fall of Napoleon, Berthier had to surrender the principality of Neuchâtel; and not to lose more, he submitted to Louis XVIII., who continued him his rank as peer and marshal. Napoleon made overtures to him from Elba; these he neither answered nor yet revealed to Louis, and this made him suspected by both. On the return of Napoleon from Elba, in a fit of irresolution Berthier retired to Bamberg, in Bavaria, to his father-in-law, Duke William. On 1st July 1815, as he looked from a window at a division of Russian troops marching towards the French frontier, the bitter sight was too much—he threw

himself down into the street, and thus ended his life. His *Mémoires* appeared in 1826.

Berthollet, COUNT CLAUDE LOUIS, one of the most distinguished theoretical chemists of his time, was born at Talloire, a village of Savoy, in 1748. He studied at Turin, and afterwards went to Paris. He now applied himself with great assiduity to chemistry; in 1781 he was elected a member of the Academy of Sciences. In 1785 he announced his adherence to the antiphlogistic doctrines of Lavoisier, whom he aided both in his researches on gunpowder and in the formation of a new chemical nomenclature. In the same year, Berthollet published a paper on 'dephlogisticated marine acid'—now called chlorine—pointing out its use for bleaching purposes; and following up the experiments of Priestley, he showed ammonia to be a compound of three volumes of hydrogen gas and one volume of nitrogen gas. During the early part of the French Revolution, he travelled through the country, giving instruction as to the process of smelting and converting iron into steel. He was made a senator by Bonaparte, who also made him a count. Notwithstanding, he voted for the deposition of Napoleon in 1814; and on the restoration of the Bourbons he was created a peer. He died at Arcueil, November 6, 1822.

Bertholletia. See BRAZIL NUTS.

Bertin, LOUIS FRANÇOIS, called Bertin l'Aîné, an eminent French journalist, was born in Paris, December 14, 1766. The Revolution made him a journalist, and in 1799 he started the famous *Journal des Débats*. His royalist principles offended Napoleon, and cost him imprisonment and banishment to Elba; thence, however, he escaped to Rome, where he formed a friendship with Châteaubriand. In 1805 he returned to Paris, and resumed the editorship of the *Débats*, but was much hampered by Napoleon. The second restoration of the Bourbons restored once more to Bertin the free control of his journal, and henceforward he gave almost constant support to the ministerial party. He supported the July monarchy, and edited the *Débats* till his death, 13th September 1841.—ARMAND LOUIS MARIE BERTIN, son of the former, was born in Paris, August 22, 1801, and became, after the restoration, secretary to Châteaubriand during his embassy in England. In 1820 he joined the editorial staff of the *Journal des Débats*, and at his father's death assumed the chief direction. He died at Paris, January 11, 1854.

Bertrand, HENRI GRATIEN, COUNT, one of Napoleon's generals, known for his faithful attachment to the emperor through all his fortunes, was born at Châteauroux (1773), and early entered the armies of the Revolution as engineer. He accompanied the expedition to Egypt, and directed the fortification of Alexandria. He distinguished himself at Austerlitz, and became the emperor's adjutant; and, after the battle of Aspern in 1809, for his share in saving the French army by bridges, he was created count and governor of Illyria. After serving with credit in the subsequent campaigns, he retired with the emperor to Elba, was his confidant in carrying out his return to France, and finally shared his banishment to St Helena. On Napoleon's death, Bertrand returned to France, where, though sentence of death had been pronounced upon him—a sentence which Louis XVIII. had wisely recalled—he was restored to all his dignities, and in 1830 appointed commandant of the Polytechnic School. In 1840 he formed part of the expedition which brought back the remains of Napoleon to France. He died at Châteauroux, January 31, 1844.

Bervic, CHARLES CLÉMENT, engraver, born at Paris in 1756, in 1790 made himself famous by a full-length engraving of Louis XVI., from the

picture by Callet, one of the finest works of the kind ever produced. He died March 23, 1822.

Bervie, a Scotch burgh and seaport in Kincardineshire, near the mouth of Bervie Water, 13 miles N.E. of Montrose by rail. It has flax and tow mills, and factories of wincey and sacking, and here in 1788 was set up the first machine for spinning yarn in Scotland. Pop. 1194.

Berwick, JAMES FITZ-JAMES, DUKE OF, was the natural son of James II., by Arabella Churchill, sister of the Duke of Marlborough. Born at Moulins in 1670, he was educated in France as a Catholic, and after serving in Hungary under Duke Charles of Lorraine (1687), returned to England shortly before the Revolution of 1688, which he exerted himself to prevent. The title Duke of Berwick was conferred on him in 1687. In 1689 he accompanied his father on his Irish expedition, and, after the death of St Ruth, had the nominal chief command. He next served in Flanders, under Marshal Luxembourg, and afterwards under the Duke of Burgundy and Marshal Villeroi. In 1706 he was created a marshal of France, and sent at the head of an army to Spain, where he established the throne of Philip V. by the decisive victory of Almansa. For this important service he was made a grandee of Spain, under the title of Duke of Liria and Xerica. After several years of comparative inactivity, he received the command in 1733 of an army intended to cross the Rhine. While besieging Philippsburg, he was killed by a cannon-ball, 12th June 1734. Contemporary testimony, confirmed by his military conduct, shows Berwick to have possessed some of the best qualities of a great commander. His defensive campaign in 1709, in Provence and Dauphiné, against the superior force of the Duke of Savoy, has always been regarded as a triumph of strategic skill. He was twice married. His son by the first marriage succeeded to the dukedom of Liria; whilst the dukedom of Fitz-James and the estates in France passed to his children by the second marriage. See his *Mémoires* (Paris, 1778); C. P. Wilson, *James II. and the Duke of Berwick* (1876); and his *Duke of Berwick, Marshal of France* (1883).

Berwick, NORTH. See NORTH BERWICK.

Berwick-on-Tweed, a seaport town at the mouth of the Tweed, on the frontiers of England and Scotland, 58 miles ESE. of Edinburgh, and 67 N. by W. of Newcastle. The liberties of the borough, called 'Berwick Bonnds,' have an area of 8 sq. m., and with Spittal and Tweedmouth, form the 'county of the borough of Berwick-on-Tweed.' Though long boasting to be neither in England nor Scotland, and still possessing separate quarter-sessions and commission of the peace, it is to all intents and purposes part of the county of Northumberland (the adjoining parts of which formed till 1844 a detached portion of Durham); especially since by the Redistribution Act of 1885 Berwick-on-Tweed ceased to send two members of its own to parliament, and was for election purposes merged in Northumberland. The town is engirt with ramparts of Elizabeth's time, and has large barracks (1719). Tweedmouth and Spittal (the latter a favourite watering-place), on the south side of the Tweed, have since 1835 both been included within the municipality of Berwick-on-Tweed. They are reached by a narrow stone bridge (1609-34) of fifteen arches; and the river is also spanned by Robert Stephenson's magnificent viaduct (1850) of 28 arches, 136 feet high and 2160 long. The public buildings include the town-hall (1760), with a belfry 150 feet high, the corn exchange (1858), and several churches, Presbyterian outnumbering the Anglican. The harbour has been improved by

the construction of a wet-dock (1873-76), at a cost of £40,000; but its trade is not very great, the tonnage of vessels entering during a twelvemonth ranging between 30,000 and 40,000. Nor is the salmon fishery what it once was. For the manufacture of agricultural implements Berwick-on-Tweed stands high, and in Spittal there are several large artificial-manure works. Pop. (1841) 12,689; (1881) 13,995; (1891) 13,378. The history of the town is full of interest, especially in regard to Border wars and the struggles of English and Scots to possess the town, the siege of Edward I. in 1296 being especially terrible. Its authentic records begin in the 12th century, when it was one of the principal seaports in the kingdom. It was annexed to England in 1333, after the battle of Halidon Hill, and was finally ceded by Scotland in 1482. See John Scott's *History of Berwick-on-Tweed* (Lond. 1888).

Berwickshire, a maritime and Border county of south-east Scotland, bounded N. by Haddington, N. and NE. by the German Ocean, SE. by Berwick-on-Tweed, Northumberland, and Roxburghshire, and W. by Roxburghshire and Midlothian. It extends from east to west 29 miles, from north to south 21 miles, and has an area of 464 sq. m., or 297,161 acres. Berwickshire is divided into three districts—the Merse, the Lammermoors, and Lauderdale. The largest and most fertile district is the luxuriant valley of the Merse, the richest plain of equal extent in Scotland, being nearly 130,000 acres in area. The Lammermoors, covering 90,000 acres, chiefly pastoral, divide the valley of the Tweed from Midlothian and Haddington. Lauderdale, comprising 67,000 acres, a mixture of hill and dale, runs along the banks of Leader Water. The coast, 19 miles in length, is rocky and bold, rising at St Abb's Head and other points to heights of from 177 to 528 feet above sea-level, and having only two bays, at Eyemouth and Coldingham. Geologically, as well as topographically, Berwickshire possesses numerous interesting features. The Lammermoors (q.v.), whose highest point in Berwickshire is Seenes Law (1683 feet), besides seventeen other summits exceeding 1240, consist of Silurian strata, stretching to St Abb's Head. In the south, carboniferous rocks are found, while an extensive bed of red sandstone extends easterly from the centre of the county to the sea-coast. On the coast porphyry is found, and some traps and syenite in the interior. Ironstone and thin seams of coal occur, as well as gypsum, clay, and shell-marl. The streams—Blackadder, Whitadder, and Leader Waters—are all tributaries of the Tweed, the Eye alone flowing direct to the sea. Pop. (1801) 30,206; (1841) 34,438; (1861) 36,613; (1891) 32,290. Berwickshire returns one member to parliament. Agriculturally, Berwickshire occupies a prominent position, 65·4 per cent. of the entire area being in cultivation. The county has suffered proportionally from the recent agricultural depression, the valuation having actually decreased from £391,169 in 1875 to £291,210 for 1895. The Earlston gingham excepted, there are no manufactures worth naming. The principal towns are Duns, the birthplace of Thomas Boston, Dr McCre, and as some contend, of Duns Scotus; Greenlaw, the county town from 1696 till 1853, but now dividing that dignity with Duns; Lauder, a royal burgh; Eyemouth, a prosperous fishing-station; Coldstream, where General Monk first raised the Coldstream Guards; and Earlston, the Ereildoune of Thomas the Rhymer. The county contains some very interesting examples, though on a comparatively small scale, of Norman or Pointed architecture, or both, at Coldingham, Dryburgh, Old Cambus, Edrom, Chirnside, Bunkle, Legerwood, and one or two other places. There are also the

remains or sites of Fast, Hume, and Cranshaws castles, and of British and Roman camps and barrows, besides remains of a curious broch-like structure at Edinshall, near Duns.

Beryl (silicate of alumina and glucina), a mineral which scarcely differs except in colour from Emerald (q.v.), never exhibiting the bright rich green which characterises that gem, but colourless, yellowish, greenish-yellow or blue. The finer varieties, which are transparent and of beautiful colour, are distinguished as Precious Beryl, and are sometimes called Aquamarine.

Beryl, in its primary form.

These occur in crystals similar in form to those of emerald; but the regular hexagonal prism is more frequently modified by truncation on the angles or edges, acummation, &c. The prisms are often long. Their sides are longitudinally

striated, often deeply so; but the truncating or terminating planes are smooth. The coarser varieties of beryl (Common Beryl) are also found crystallised, but often massive. Beryl occurs chiefly in veins that traverse granite or gneiss, or imbedded in granite; sometimes it is found in alluvial soils formed from such rocks. Common beryl is found in a number of places in Europe. The mountains of Aberdeenshire, and those of Mourne in Ireland, yield precious beryl, which is also found in various parts of the United States, Brazil, Ceylon, and Siberia. It is somewhat less valuable than the emerald. For its use as a magic crystal, in which the future becomes visible, see Rossetti's *Rose Mary*.

Beryllium. See GLUCINUM.

Berzelius, JOHAN JAKOB, BARON, one of the founders of the science of chemistry, was born at a farm in East Gothland, Sweden, August 29, 1779. While studying for the medical profession at the university of Upsala, he was more attracted by the preparatory studies in science, especially chemistry. After being some time employed in medical practice and lecturing, he was appointed (1806) lecturer on chemistry in the Military Academy of Stockholm, and, in the following year, professor of Medicine and Pharmacy. He was shortly after chosen president of the Stockholm Academy of Sciences; and from 1818 till his death, August 7, 1848, held the office of perpetual secretary. The king raised him to the rank of baron; other honours from learned societies were conferred on him, including the London Royal Society's gold medal. The field of his activity lay in his laboratory, where he acquired a name of which his country, where he ranks in science second only to Linnæus, is justly proud. The science of chemistry, as at present organised, rests in great measure upon the discoveries and views of Berzelius, although in not a few points he has been controverted or found wrong. His multiplied and accurate analyses established the laws of combination on an incontrovertible basis; and to him we owe the system of chemical symbols. He discovered the elements selenium, thorium, and cerium, and first exhibited calcium, barium, strontium, columbium or tantalum, silicium, and zirconium, in the metallic form. The multitude and accuracy of his researches in every branch of chemical inquiry, as well as in physics and physiology, make it difficult

to conceive how one man could have accomplished so much. Of his numerous writings, the most important is his *Lärobok i Kemi* (Text-book of Chemistry, 3 vols. Stock. 1808-18), which afterwards passed through five large editions, on each occasion being almost wholly rewritten, and which was translated into every European language. His essay *On the use of the Blowpipe* exhausts the subject, and in that *On the Division of Salts through Galeanism* he propounds the electro-chemical theory, the title to which is divided between himself and Davy; while his *Annual Reports on the Progress of Physics, Chemistry, and Mineralogy*, undertaken at the request of the Academy of Sciences in 1820, proved very valuable to science.

Besançon, a French city, the capital now of the department of Doubs, and formerly of Franche-Comté, is picturesquely situated on both sides of the winding river Doubs, 57 miles E. of Dijon. It was strongly but irregularly fortified by Vauban, the citadel being perched on an inaccessible rock, 390 feet above the town. Since then, the fortifications have been extended and strengthened, and Besançon is now considered one of the strongest places in France. It was the ancient *Vesontio* or *Besontium*; in 58 B.C. Cesar expelled the Sequani hence, and in the neighbourhood gained a victory over Ariovistus. It finally came into the possession of France in 1674. Several streets in Besançon still bear old Roman names; and in the neighbourhood are found ruins of a triumphal arch of Aurelian, an aqueduct, an amphitheatre, and a large theatre. Among later structures the 12th-century cathedral, the Madeleine church, the Prefecture, the Palais de Justice (1749), and the half-Gothic, half-Renaissance palace (1534) of Cardinal Granvella, are most remarkable. Besançon makes a very large percentage of the watches made in France, and some 15,000 of its inhabitants are engaged in this industry, which was introduced from Switzerland about 1818. In 1875-85 Besançon produced between 400,000 and 450,000 watches annually, worth from twenty to thirty millions of francs. Other manufactures are porcelain, carpets, iron-wire, Seltzer-water, and beer. Abel Rémusat and Victor Hugo were natives. Pop. (1840) 36,461; (1886) 45,218; (1891) 44,793.

Besant, SIR WALTER, a well-known novelist, was born at Portsmouth in 1838. He studied at King's College, London, and at Christ's College, Cambridge, and having abandoned his original intention of entering the church, was appointed to a professorship in the Royal College of Mauritius. Ill-health compelling him to resign this post, he returned to England and devoted himself to literature. His first work, *Studies in French Poetry*, appeared in 1868, and in 1871 he entered into a literary partnership with James Rice. *Ready-money Mortibag*, the first of the novels which were the fruits of this conjoint authorship, was published in 1872. It was followed by *My Little Girl: With Harp and Crown*; *This Son of Udeau*; *The Golden Butterfly* (1876), which greatly increased the popularity of its authors; *The Monks of Thelema*; *By Celic's Arbour*; *The Chaplain of the Fleet*; and *The Seamy Side* (1881). After the death of Rice (q.v.), Besant (who was knighted in 1895) wrote *All Sorts and Conditions of Men*, *The Captain's Room*, *All in a Garden Fair*, *Dorothy Forster*, *Children of Gibbon*, *The World went very well then*, *Beyond the Dreams of Avarice*, *The Master Craftsman* (1896), &c.; also *French Humourists* (1873), short books on Rabelais, Coligny, and Whittington, a life of Professor Palmer (1883), and works on London (1892) and Westminster (1895); also DICKENS, JERUSALEM, PALESTINE, and RABELAIS in this work. He shows a first-

hand knowledge of very various phases of life, grasp of character, constructive skill, and humour at once shrewd and genial. The distinguishing feature of his novels is the interplay of ingenious fancy and thorough-going, healthy realism. His plots are sometimes as whimsical and charming as a fairy tale, while the setting of each story is worked out with scrupulous fidelity to local colour. In such a book as *All Sorts and Conditions of Men*, romance and realism are combined with the happiest results. Some of his later novels have been written for the furtherance of social reforms, and one of his schemes, the People's Palace, described in *All Sorts and Conditions of Men*, has been happily carried into effect in the east end of London. As secretary of the Palestine Exploration Fund, he has edited various works on the survey of Palestine; and he was first chairman of the committee of the Incorporated Society of Authors. See the Introduction to the library edition of *Ready-money Mortiboy* (1887).

Besants'. See BEZANTS.

Besika Bay. a bay on the north-west coast of Asia Minor, opposite Tenedos, to the south of the entrance of the Dardanelles. The English fleet was stationed here during crises in the Eastern Question, in 1853-54 and 1877-78.

Bessarabia. a government in the south-west of Russia, on the Roumanian frontier. The area, enlarged by the restoration in 1878 of the portion ceded to Moldavia in 1856, is 17,627 sq. m.: the population in 1893 was 1,688,600, composed of Russians, Poles, Roumanians, Bulgarians, Greeks, Armenians, Jews, Germans, and Tartars, with a sprinkling of Gipsies. The Dniester flows along the whole of its northern and eastern boundaries; the Pruth separates it from Moldavia on the west; and it has the Danube on the south. In the north-west, the country is traversed by well-wooded offshoots of the Carpathian Mountains. Generally, however, Bessarabia is flat and fertile. The land is cultivated to some extent; but the breeding of cattle forms the chief business of the inhabitants. Salt, cattle, wool, and tallow are exported; leather, soap, and candles are manufactured. Bessarabia, which fell under the power of the Turks in 1503, suffered heavily in all wars with Russia, and was ceded to Russia in 1812. By the Treaty of Paris, the portions of Bessarabia lying along the Pruth and the Danube—3578 sq. m., with some 200,000 inhabitants—were assigned to Moldavia; at the Berlin Congress of 1878, this region was again transferred to Russia.

Bessarion. JOHANNES (or *Basilus*), born at Trebizond, on the Black Sea, in 1395, was one of the earliest of those scholars who in the 15th century transplanted Greek literature and philosophy into the West, and rescued the mind of Christendom from the trammels of scholasticism. As Bishop of Nicaea, he accompanied the Greek emperor, John Paleologus, to Italy in 1439 in order to effect a union between the Greek and the Roman churches. Soon afterwards joining the Roman Church, he was made cardinal by Pope Eugene IV. Ten years later, Nicholas V. created him Bishop of Frascati. For five years also he discharged the duties of papal legate at Bologna. After the fall of Constantinople, of which he had been titular patriarch, he visited Germany, and endeavoured to promote a crusade against the Turks. In philosophy, he professed to be a follower of Plato, but without depreciation of Aristotle. Twice he was nearly elected pope; but his partiality for the heathen philosophy, or his Greek birth, disqualified him with the sacred college. He died at Ravenna in 1472, leaving his collection of 600 valuable Greek MSS. to the St Mark's Library, Venice.

Bessèges, a town in the French department of Gard, 21 miles N. of Alais. It has coal, iron, and glass industries. Pop. 8068.

Bessel. FRIEDRICH WILHELM, an eminent Prussian astronomer, born at Minden in 1784. Successively a merchant's clerk, a supercargo on board ship, and a practical astronomer, he was in 1810 appointed director of the observatory at Königsberg, and professor of Astronomy there. In 1818 he published his *Fundamenta Astronomiæ*—a work which was of the highest value to astronomers; and in 1830 his *Tabulæ Regiomontanae*. Among the numerous papers may be mentioned his treatise on the precession of the equinoxes. After a series of three years' observations he succeeded in determining the annual parallax of the fixed star 61 Cygni (see STARS). In the years 1824-33 Bessel made a series of 75,011 observations in 536 sittings, and completed a catalogue of stars (extending to the ninth magnitude) within the zone from 15° N. to 15° S. declination; and published *Astronomische Untersuchungen* (1842) and other works. His *Popular Lectures on Astronomy* were published two years after his death, which took place March 14, 1846. He was a thoroughly practical man of science, was remarkable for the precision of his calculations, introduced many new methods, and greatly forwarded the science of astronomy.

Bessemer. SIR HENRY, F.R.S., inventor, born 19th January 1813, at Charlton, Herts, was the son of a French artist, and was to a great extent self-taught. He was a prolific inventor, as the volumes issued by the Patent Office show; indeed, it was said he paid in patent stamp duties alone as much as £10,000. The working out of many of his inventions, however, resulted in a loss to himself and to others. His first pecuniary success was obtained by his invention of machinery for the manufacture of Bessemer gold and bronze powders, which was not patented, but whose nature was long kept secret. His process for the manufacture of steel, noticed below, raised the annual production of steel in England from 50,000 tons by the older processes to as many as 1,600,000 tons in some years. Bessemer steel is also largely made abroad. This steel soon averaged £10 per ton, while the price of (much finer) steel before the introduction of his process averaged not less than £50 per ton. Bessemer was knighted in 1879, and received many gold medals from scientific institutions. In addition he had, to use his own words, received in the form of royalties 1,057,748 of the beautiful little gold medals issued by Her Majesty's Mint. He died 15th March 1898.

BESSEMER STEEL.—Sir Henry Bessemer's process for making steel, which is now so largely practised in England, on the continent of Europe, and in America, was patented in 1856. It was first applied to the making of malleable iron, but this has never been successfully made by the Bessemer method. For the manufacture of a cheap but highly serviceable steel, however, its success has been so splendid that no other metallurgical process has given its inventor so great a renown. Although the apparatus actually used is somewhat costly and elaborate, yet the principle of the operation is very simple. A large converting vessel (see annexed figure), with openings called *truyères* in its bottom, is partially filled up with from 5 to 10 tons of molten pig-iron, and a blast of air, at a pressure of from 18 to 20 lb. per square inch, is forced through this metal by a blowing engine. Pig-iron contains from 3 to 5 per cent. of carbon, and, if it has been smelted with charcoal from a pure ore, as is the case with Swedish iron, the blast is continued till only from .25 to 1 per cent. of the

carbon is left in the metal, that is to say, steel is produced. Sometimes, however, the minimum quantity of carbon is even less than .25 per cent. In England, where a less pure but still expensive cast-iron—viz. hematite pig—is used for the production of steel in the ordinary Bessemer converter,

Bessemer Converting Vessel :
a, a, a, tuyères; b, air-space; c, melted metal.

the process differs slightly. In this case the whole of the carbon is oxidised by the blast of air, and the requisite quantity of this element is afterwards restored to the metal by pouring into the converter a small quantity of a peculiar kind of cast-iron, called *spiegeleisen*, which contains a known quantity of carbon. But small quantities of manganese and silicon are also present in Bessemer steel. The 'blow' lasts from 20 to 30 minutes. Steel made from whatever kind of pig-iron, either by this or by the 'basic' process, presently to be described, is not sufficiently dense, at least for most purposes, and it is accordingly manipulated under the steam-hammer and rolled into a variety of forms. Bessemer steel is employed for heavy objects, as rails, tires, rollers, boiler plates, ship plates, and for many other purposes for which malleable iron was formerly used.

Basic Steel.—This kind of steel is now largely made from inferior pig-iron, such as the Cleveland, by the Thomas-Gilchrist process patented in 1878. It is, however, only a modification of the Bessemer process to the extent of substituting for the siliceous or 'acid' lining generally used, a lime or 'basic' lining for the converter. Limestone, preferably a magnesian limestone in some form, is commonly employed for the lining. By the use of a basic lining, phosphorus is eliminated towards the end of the 'blow.' Phosphorus is a very deleterious substance in steel, and is present, sometimes to the extent of 2 per cent., in pig-iron smelted from impure ore.

Bessières, JEAN BAPTISTE, Duke of Istria, and Marshal of the French empire, was born of poor parents at Preissac, in the department of Lot, 6th August 1768. Entering the army in 1792 as a private soldier, in less than two years he had attained the rank of captain. After making the Spanish campaign he passed into the army of Italy, and soon attracted the notice of Napoleon, who carried him to Egypt in 1798, where his

conduct at St Jean d'Acre and Aboukir covered him with glory. At the accession of Napoleon (1804) to the throne, he became marshal of France. He showed his usual conspicuous courage at Austerlitz, Jena, Eylau, and Friedland, and raised to the rank of Duke of Istria, commanded in Spain in 1808-9. In the Russian campaign he led the cavalry of the Guard, and did much by his sleepless courage and presence of mind to save the wreck of the army in the disastrous retreat from Moscow. On the morning of the battle of Lützen (May 1, 1813), he fell mortally wounded by a cannon-ball.

Bestiary (Fr.), the name given to a class of written books of great popularity in the middle ages, describing all the animals of creation, real or fabled, composed partly in prose, partly in verse, and generally illustrated by drawings. But they were valuable for the moral allegories they contained, no less than as handbooks of zoological facts. The symbolism which was then so much in vogue fastened spiritual meanings upon the several animals, until every quality of good or evil in the soul of man had its type in the beast world. It is in this way to the bestiaries that we must look for explanation of the strange, grotesque creatures which are found sculptured on the churches and other buildings of the middle ages. The oldest Latin bestiaries had an early Greek original, the well-known *Physiologus*, under which name about fifty such allegories were grouped. The Greek text of this famous work is found only in MS. There are old Syriac, Armenian, Ethiopic, Arabic, Icelandic, and numerous Latin versions. Editions of the Latin have been issued—Mai, Heider, and Cahier. An Old High German version was made earlier than the 11th century; in the 12th century, versions in French were made by Philippe de Thann and Guillaume, a priest of Normandy. The *Bestiaire d'Amour* of Richard de Fournival was rather a parody upon the earlier form of such books. The following is a characteristic extract from the *Bestiaire Divin*: 'The unicorn has but one horn in the middle of its forehead. It is the only animal that ventures to attack the elephant; and so sharp is the nail of its foot, that with one blow it rips up the belly of that most terrible of all beasts. The hunters can catch the unicorn only by placing a young virgin in the forest which it haunts. No sooner does this marvellous animal desery the damsel, than it runs towards her, lies down at her feet, and so suffers itself to be taken by the hunters. The unicorn represents our Lord Jesus Christ, who, taking our humanity upon him in the Virgin's womb, was betrayed by the wicked Jews, and delivered into the hands of Pilate. Its one horn signifies the gospel truth, that Christ is one with the Father,' &c.

Bestushev, ALEXANDER, a Russian novelist, born in 1793, was an officer in the guards, and became involved in the military conspiracy of 1825, in consequence of which he was degraded to the ranks, and exiled to Yakutsk. After long entreaty he was permitted to enter the army of the Caucasus as a private in 1830. In June 1837 he fell in a skirmish with the as yet unconquered mountaineers. His novels and sketches bore the impress of his own life and adventures in the Caucasus.

Betanzos (anciently *Brigantium Flarium*), a town of Spain, 10 miles SE. of Comnna. Pop. 8122.

Betel, properly the leaf of the betel-vine, a plant (*Charica betle*, *C. siraboa*, &c.) of the natural order Piperaceæ, indigenous to the East Indian Archipelago, and cultivated also in continental India, Ceylon, and several of the Indo-Chinese countries (Burmah, Siam, &c.), but more

or less as an exotic according as the necessary conditions of humidity and heat have to be artificially increased. The name betel (a Malayalam and Tamil word for 'leaf') is frequently applied to the bolus of areca-nut and shell-lime (*chunam*) wrapped round with betel-leaf, employed as a masticatory throughout a large part of the farther East, especially by the Malay and Hindu races. As early as Fryer (1673) betel begins to be used erroneously as a synonym for the nut of the Areca (q.v.) palm. Betel-leaf (Hindustani, *pān* or *pawn*; Persian, *tambul*; Malay, *sirih*) is described in glowing terms in the *Hitopadesa*, book iii., fable 9. The ancient Hindu writers recommend it to be taken early in the morning after meals, and at bedtime. Pills against phlegm are rubbed into an emulsion with the juice; and the leaves are applied to remove headache, reduce swollen glands, or check the secretion of milk. The use of the masticatory has become a matter of etiquette, and the betel-box plays as important a part as the snuff-box did in England in the 18th century. In India the offering of *pawn* by the host intimates the termination of a visit. Among the Malays of the Archipelago to offer *sirih* is accepted as a legal sign of apology for a serious offence. Europeans seldom take kindly to the habit of chewing betel,

Betel-vine.

partly because it blackens the teeth and causes the lips to appear as if covered with blood. Sir James Emerson Tennent (*Ceylon*) considers that it supplies the antacid, the tonic, and the carminative required by a people who usually eat no flesh. In former days the betel-leaf was a monopoly of the East India Company. The cultivation of the plant is in many districts a highly important industry, and requires considerable capital. In Bombay, betel-vines are put down in October, 3600 to 5000 per acre. They are sheltered from drought by plantains grown along with them, and by bamboo stages covered with grass. These are afterwards replaced by stronger and taller trellis-work up which the plants climb luxuriantly. In Tenasserim, again, the Karens train the vines to forest-trees from which all but the topmost boughs have been lopped off. See Marsden's *History of Sumatra*; Curtis's *Botanical Magazine* (vol. vi. new series); Miguel, *Systema Piperacearum*; Hunter's *Gazetteer of India*.

Beth'any ('house of dates'), by the natives of Palestine called 'El' Azariyeh' or 'Lazariyeh'

('town of Lazarus'), is situated on the southern slope of the Mount of Olives, 2208 feet above the sea, 2 miles ESE. of Jerusalem. It was the home of Lazarus and his sisters, often visited by the Saviour, and the scene of his ascension. Ecclesiastical buildings were erected here in the 4th century, but it is now a poor place of some 200 inhabitants. There is nothing remarkable about the village except the reputed house of Martha and Mary, and the cave or grave of Lazarus shown by the monks. Major Conder thinks it more likely that the tomb of Lazarus is one of the rock-cut sepulchres beside the Jericho road, east of Bethany.—Bethany is also the name that has been given to three German mission stations in South Africa: one in Great Namaqualand, one in the Orange Free State, and one in the Transvaal.

Beth'el ('house of God'), now called Beitin, about 11 miles N. from Jerusalem, mentioned in Scripture as the scene of Jacob's dream. The old name of the place was Luz. Here Abraham pitched his tent; at a later date it was a resting-place of the ark, a royal residence, and a seat of idolatrous worship. It is a heap of ruins.

Bethes'da, POOL OF ('house of mercy' or 'house of the stream'), the scene of Christ's cure of the impotent man (St John, v. 2-9), the tank that was the resort of the 'impotent, blind, halt, and withered.' Since 1102 it has been identified with the Birket Israil, which is situated within the walls of Jerusalem, near the St Stephen's gate and the Temple of Omar. Conder, however, identifies it with the spring in the Kedron Valley called Gihon and En Rogel, which was diverted through a rock-cut tunnel to Siloam. But Schick in 1889 discovered the remains of the substructures of the pool near the church of St Anne.

Bethesda is a small town of Carnarvonshire (so named from its Nonconformist chapel), 4½ miles SE. of Bangor. Its 5799 inhabitants are mostly employed in the neighbouring Penrlyn slate-quarries.

Bethlehem ('house of bread'; modern *Beit-lahm*), the birthplace of Jesus Christ and of King David, and the Ephrathah of the history of Jacob, is now a small unwall'd village of white stone houses, in the midst of a most interesting country, 6 miles S. of Jerusalem. The population, about 3000 souls, is wholly Christian—Latin, Greek, and Armenian. The Convent of the Nativity, a large square building, resembling a fortress, was built by the Empress Helena, 327 A.D., but destroyed by the Moslems in 1236, and, it is supposed, restored by the Crusaders. Within it is the Church of the Nativity, which is subdivided among the Latins, Greeks, and Armenians, for devotional purposes. The church is built in the form of a cross; the nave, which is by far the finest part of the building, belongs to the Armenians, and is supported by 48 beautiful Corinthian columns of solid granite, each between 2 and 3 feet in thickness, and about 17 in height. The other portions of the church, forming the arms of the cross, are walled up. At the farther end of that section, which forms the head of the cross, and on the threshold, is a sculptured marble star, which the Bethlehemites say covers the central point of the earth. Here a long intricate passage descends to the crypt below, where the blessed Virgin is said to have been delivered. The walls of the chamber are hung with draperies of the gayest colours; and a silver star, with the words, '*Hic de virgine Maria Jesus Christus natus est*,' marks the spot of the nativity. The manger stands in a low recess cut in the rock. The site appears to have been venerated since the

2d century A.D., and St Jerome, a monk of this convent towards the end of the 4th century, found the grotto in possession of pagans, who celebrated here the birth of Adonis. To the north-west stands

than a hostile invasion, and on arriving under the walls of Presburg, was greeted with acclamations by the citizens. He was subsequently crowned king of Hungary by the assembled diet, August 25,

1621. After various alternations of fortune, in which he was ultimately successful, a peace was in 1621 concluded with Ferdinand II. of Austria, by which Gabor gave up his claims to Hungary and the title of king, but obtained large accessions of territory, and the dignity of prince of the empire. This treaty, however, was soon broken by the emperor; but the prince raised an army of 60,000 men, invaded Moravia, and obtained the solemn renewal of the former treaty. He died in 1629. His reign was a glorious epoch in the history of the principality; for not only did his military successes give a prestige to its arms, but his protection of science and letters did much to aid the progress of learning.

Bethnal Green, an eastern suburb of London, since 1885 a parliamentary borough. It is

largely peopled by silk-weavers, an offshoot of the Huguenot settlement in Spital-fields. Its museum, opened by the Queen in 1872, is a branch of the one at South Kensington. Pop. (1881) 126,961; (1891) 129,134.

Bethsaida, a village on the western shore of the Lake of Galilee, the birthplace of Peter and Andrew and Philip. Its site has been identified with a heap of grass-grown ruins.—At the north-eastern extremity of the lake was another Bethsaida, a village, near which the five thousand were fed. Philip the Tetrarch raised it to the dignity of a town, and renamed it Julius, in honour of the Emperor Augustus's daughter.

Bethune, a town in the French department of Pas-de-Calais, on a rock overlooking the river Brette, 16 miles NNW. of Arras, with old fortifications by Vauban. It has bleaching-works, manufactures of soap, and a trade in beet-sugar. Pop. 11,098. The town was Flemish till 1713. Sully (q.v.) belonged to the family founded here in 970. The Scottish family of Bethune or Beaton (q.v.) is said to have come hence to England with William the Conqueror.

Bet'ony. See STACHYS.

Betterment, an improvement to real property made by a tenant such as justifies him in claiming compensation from the landlord. A betterment tax is one assessed on property benefited by a public improvement. See INCREMENT (UNEARNED).

Betterton, THOMAS, actor, was born in London about 1635, and, after serving as a bookseller's apprentice, turned actor some three years before the Restoration, and in 1661 joined Davenant's theatrical company. The best contemporary judges, such as Addison, Cibber, Dryden, &c., bear admiring witness to his dramatic powers, which overcame the natural disadvantages of a low voice, small eyes, and an ungainly figure. Pepys thought him the best actor in the world, and he was patronised by royalty. His private character was highly estimable, cheerful, modest, and generous. In an unfortunate speculation in 1692 Betterton lost all his savings. When in straitened circumstances and able to act less frequently, a public benefit was got up for him on the 6th April 1709,

Bethlehem.
(From a Photograph by Frith.)

a square domed building, marking the reputed site of Rachel's tomb. The Bethlehemites chiefly gain their subsistence by the manufacture and sale of crucifixes, beads, boxes, shells, &c. of mother-of-pearl and olive wood.

Bethlehem, a post-borough of Northampton county, Pennsylvania, on the Lehigh River, 55 miles N. of Philadelphia by rail, is the principal settlement in America of the Moravians, by whom it was founded in 1741. It has silk, paint, and flour mills, and is noted for its excellent schools. Two bridges across the Lehigh connect the borough with South Bethlehem, the seat of Lehigh University (1866) and other Episcopal institutions, and possessing iron and steel works. Another borough, West Bethlehem, separated from Bethlehem by Monocacy Creek, contains silk and planing mills, machine-shops, and dye-works. Pop. (1890) 6762; of South Bethlehem, 10,302; and of the three boroughs, 15,000.

Bethlehemites, (1) a monastic order existing in England in the 13th century, who had a monastery at Cambridge, founded in 1257.—(2) A military order established by a bull of Pius II. in 1459, to provide a bulwark against the attacks of the Turks.—(3) A society founded in Guatemala about 1659, and raised to an order by Innocent XI. in 1687.—The followers of John Huss were styled Bethlehemites, from Bethlehem Church in Prague, where their leader preached.

Bethlem. See BEDLAM.

Bethlen-Gabor (i.e. GABRIEL BETHLEN), descended from an ancient and distinguished Protestant family of Hungary, was born in 1580. He rose to prominence during civil troubles in Transylvania, and on the death of Gabriel Bathori succeeded (1613), by the aid of the sultan, in being chosen sovereign prince of Transylvania. In 1619, when the Bohemians rose in defence of their religious and political rights, they looked eagerly for support to Gabor, who was glad of such an opportunity to gratify his ambition at the expense of his enemy, Austria. He accordingly marched into Hungary, took Kaschau, his advance more resembling a triumphal procession

and he acted several times again before his death on 28th April 1710. He was buried in Westminster Abbey. Mrs Betterton, whom he had married in 1662, took the same rank among contemporary actresses as her husband did among actors. Betterton's own eight dramas were adaptations. See Dr Doran, *Their Majesties' Servants* (2d ed. by R. W. Lowe, 1887); and the Life by R. W. Lowe (1891).

Bettia, a municipal town in the north-west corner of Behar, India, on the line of the Tirhut state railway. Pop. 22,780, of whom about two-thirds were Hindus. There has been a Roman Catholic mission here since 1746.

Betting may just now be termed a national craze, for more persons bet now than ever, though individual speculations may not be on as large a scale as formerly. For this state of things several reasons may be submitted. Racecourses and race-meetings have multiplied; sporting intelligence is more widely disseminated by means of press agencies, telegrams, and evening papers; while coursing in inclosed grounds has given an impetus to wagering in connection with that branch of sport. There is also an increased number of bookmakers plying their calling, and the growth of betting may be further assumed from the fact that members of the fraternity are constantly localising themselves in provincial towns; while it is not uncommon for a tradesman in a town to do a commission business on a large scale. The betting world consists of two great divisions, bookmakers and backers. In theory, bookmaking is a very simple business. The bookmaker makes a book of a certain amount, a hundred, a thousand, or a ten thousand pound book, and his aim is to lay an equal amount against every horse in a race—a hundred pounds, assuming the book to be a hundred pound one. The rate of odds will of course vary with the market quotations of each horse. If there are five starters for a race, one of which is at level money, the bookmaker will lay £100 level. Against another at 2 to 1 he will lay £100 to £50; against a third at 5 to 1 he will lay £100 to £20, and so on; though the amount laid against each horse may have to be made up of many bets.

In practice, however, bookmaking is a much more complicated business, and calls for great quickness, industry, and a head for figures. It is seldom that the bookmaker succeeds in laying against even a large proportion of starters; and when the majority of races are won by favourites, the day's balance is in favour of backers. Of backers there are two classes, those who bet more or less, because it provides them with amusement and adds to the interest of a race, and 'professional backers,' as they are styled, who endeavour to make a living by attending race-meetings and backing horses. 'Touting' has now been brought to a fine art, and the bookmaker has little if anything the better of the professional backer in obtaining information; consequently, in the race between the two classes there is not a very great margin on the side of the bookmaker, whose riches come from the pockets of the general public. 'Hedging' is an important operation in betting, and consists in laying the odds against a horse which the person desirous of hedging has previously backed at a longer price. For example, suppose a horse backed for £1 by A for a future race at 30 to 1, comes to 10 to 1 say a month before the race is to be decided. A then lays the latter odds against the horse, and thus stands £20 to nothing. If the horse wins, he gets the £30 for which he backed the horse, and loses the £10 he laid against him; should the horse lose he pays the bookmaker £1, and receives £1.

Betting has probably existed ever since there was anything to bet about; but in the early history of

horseracing (with which betting is chiefly connected) there were no professional betting men, and gentlemen had to bet with one another, the result being, that those desirous of backing a horse often experienced great difficulty in finding any one to bet with them. The demand, however, created the supply, and 'bettors round' or 'legs,' as the phrase then ran, sprang into existence; though book-making can hardly be said to have become a science until the time of William Ogden, about 1793. Since that day betting has undergone a great change. Time was when a great amount of wagering took place many months before the more important races were set for decision, whereas now the bulk of the speculation goes on when the numbers of the horses are hoisted just prior to the start. Foal and yearling books, too, are now never heard of.

The manner in which the law regards betting has had a not unimportant influence on the method in which it is carried on. A bet *per se* is not illegal, it is only void at law—that is to say, neither party can bring an action to enforce payment. Where betting is carried out upon a tolerably extensive scale, it has been found convenient to employ a 'commissioner,' who makes bets for his principal, pays or receives, as the case may be, and then renders his statement. Although if A made a bet with C neither party could recover, it has been held that if A were to employ B as a commissioner, A could bring an action against B to recover what had been paid him by C, in the event of A winning, and that B could successfully sue A for the amount of bets lost by A, and paid to C by B. The result of this ruling has been to encourage the business of a 'turf-accountant,' otherwise a commission agent.

Betting houses were forbidden in 1853 by 16 and 17 Vict. chap. 119, commonly known as Cockburn's Act, from the bill having been introduced by the late Lord Chief-justice, Sir Alexander Cockburn. The act, however, did not extend to Scotland, so the bookmakers removed their establishments across the Border, settling chiefly in Glasgow. They carried on their business with immunity from legal proceedings until 1874, when the Act 37 Vict. chap. 15 was passed. This statute, by extending Cockburn's Act to Scotland, again ousted the betting men, who thereupon took refuge in Boulogne, whence they were expelled in 1891. The Act of 1874 contained further provisions to suppress betting advertisements; but they do not reach tipsters; the act only makes it illegal to advertise willingness to give information on bets themselves, not to advise how to bet.

At the Ascot meeting of 1887, two welshers were given into custody for attempting to run away with money which had been deposited with them by one of the public, who had backed a winning horse with them. The magistrates convicted the prisoners, and the Court for the Consideration of Crown Cases Reserved affirmed the conviction, thus making welshing a felony. An act of 1892 made penal the inciting of infants (young persons) to betting, wagering, or borrowing money.

Cockburn's Act put a stop to the exhibiting of 'lists' in public-houses, an invention of Davies, the 'leviathan,' who, after beginning life as a jobbing carpenter, rose to the position of the most influential man in the ring. He had scarcely been a bookmaker for eight years, when he was supposed to have commenced the racing season of 1852 with £140,000 lying to his credit at the London and Westminster Bank. It occasionally happened that he encountered severe losses. In the Flying Dutchman's year (1849) he paid away nearly every pound he possessed; and his list clerks alone paid away more than £40,000 over Veltiger. In 1853 he is reported to have won more than £50,000 over the Cesarewitch and Cambridgeshire. The famous

Lord George Bentinck won £20,000 by Crucifix's victory in the Oaks in 1840, and all her successes are said to have put £70,000, exclusive of stakes, into the pocket of her owner. In 1843 Lord George stood to win £150,000 over his horse Gaper for the Derby on that year, but he saved upon Cotherstone, and netted £30,000. When John Gully and Ridsdale were partners, their joint winnings are said to have been enormous. St Giles and Margrave brought them in upwards of £100,000 by winning the Derby and St Leger in 1832. Sir Joseph Hawley was one of the heaviest bettors of his day; he pocketed £80,000 over Beadsman's Derby in 1855, and many other large sums at other times. 'He took away as much of the plunger's money as any half-dozen bookmakers put together; yet while his two-year-olds were winning races, and he was winning large bets, he was at the same time advocating the abolition of two-year-old racing, and was declaiming against heavy betting! The unfortunate Marquis of Hastings lost £103,000 over Hermit's Derby, and it was soon after his time that plunging went out of fashion. Two others have tried it since, but failed to win, and it may be safely said that men do not now bet such large sums as formerly; no modern speculator would care to lay £90,000 to £30,000, a bet which is said to have been booked between the old Lord Glasgow and Lord George Bentinck. The morality of betting need not be here discussed; but it is noteworthy that the notorious O'Kelly, the owner of Eclipse, who owed nearly all he possessed to successful betting and gaming, provided, on leaving his Clay Hill estate to his nephew, that the latter should forfeit £500 for every bet he made upon horseracing; and at least two others, who owed their position to betting, adopted a similar course with regard to the recipients of their property.

The use of a betting apparatus called a 'Pari-mutuel,' deserves a word of notice, owing to the action, in 1887, of the French authorities with regard to the bookmakers. The 'Pari-mutuel' is a large frame, with a number of purse-like receptacles on it, each receptacle being devoted to a separate horse. The intending backer places his stake in the purse appropriated to the horse of his fancy, and when the race has been won, the backers of the winner divide among themselves all the money staked upon the different horses, less ten per cent, which goes to the proprietor of the machine. This method of gambling differs from ordinary betting, in so far as there are no regular odds against any of the starters. Suppose, for instance, that four horses are engaged in a race, and that the stake is 5s. Ten persons may back A the favourite, five may fancy B, while C and D may only have one supporter each. The machine will thus contain seventeen contributions, amounting to 85s. in all. Should A win, the ten backers have 85s. to divide between them; so each would get 3s. 6d. in addition to his original stake of 5s.; in other words they would be laying about 6 to 4 on the winner. If, on the other hand, C or D won, the solitary backer of either would take the whole of the 85s., equivalent to having taken 10 to 1 about the winner. The 'Pari-mutuel' was introduced into France about 1865, and found its way to England about 1868 or 1869. Its use gave rise in 1870 to the case of *Tullet v. Thomas*, in which it was held to be a gaming machine, and therefore illegal. On nearly every racecourse are seen placards stating that 'Illegal betting is strictly prohibited.' This illegal betting consists in the backer depositing his money at the time of making the bet. So long as they bet on credit, the parties are safe from molestation on a racecourse. Of betting the Jockey Club takes no cognisance,

though this was not always the case, as they met and settled a disputed case which arose in connection with the Ascot meeting of 1815. Matters connected with betting are now ruled by the committees of Tattersall's and the Newmarket Rooms, and in February 1886 Tattersall's overhauled the rules of betting, and made some alterations; the most important of them being with regard to defaulters, and a declaration that all races should thenceforth be 'Play or Pay.' See *Tattersall's Rules on Betting*, by Stutfield (1888).

Bettws-y-Coed, a village in Carnarvonshire, North Wales, beautifully situated at the point where the Conway receives the Llugwy, 15 miles S. of Llandudno Junction by rail. The rich greenery of the vegetation, the waterfalls and streams, the luxuriantly wooded hills all round, with the background of the mighty Snowdon and her sister-peaks, combine to make Bettws-y-Coed almost unique in the variety of its natural beauty. At the 'Royal Oak' is a former signboard, painted by David Cox, who stayed here every year from 1844 to 1856. Pop. 744.

Betty, WILLIAM HENRY WEST, better known as the Young Roscius, born at Shrewsbury in 1791, first appeared on the stage at the age of eleven in Belfast, and achieved an immediate success. For almost five years he sustained the heaviest parts before crowded and enthusiastic audiences, and earned from 50 to 75 guineas nightly. In 1805 Mr Pitt adjourned the House of Commons to permit members to witness the boy's Hamlet. He quitted the stage as a boy-actor in 1808, but after studying for a while at Cambridge, returned to it in 1812. He retired finally in 1824, and lived for fifty years in the enjoyment of the fortune he had so early amassed. He died in London, August 24, 1874.

Betula. See BIRCH.

Betwa, a river in Bundelkhand, North-west Provinces, India, which, after a north-east course of 360 miles, joins the Jumna.

Beust, FRIEDRICH FERDINAND, COUNT VON, German statesman, one of the most prominent modern politicians, was born at Dresden, January 13, 1809. Having conceived early a liking for politics, he devoted himself to diplomacy, and was employed by his government in various capacities in Berlin, Paris, and London. As minister for foreign affairs for Saxony, he, in 1849, declared against the adoption of the new German constitution, but in 1863 he supported the rights of the smaller German states on the Schleswig-Holstein question. In 1866, however, his friendship for Austria induced him to join that country in the war with Prussia, against the wishes of at least the liberal party in Saxony. He afterwards entered the service of Austria, and rose in 1867 to the head of affairs. The chief result of his policy in the reorganisation of the empire was the reconciliation of Hungary, although he afterwards disclaimed the honour of introducing dualism into the empire, and declared that he did so because only Déak's plan would satisfy Hungary. A zealous Protestant, he was an opponent of the Ultramontanes, and his tenure of office saw the removal of Jewish disabilities, and the establishment of civil marriages. Having failed in 1870 to keep his engagements to France, he resigned the office of chancellor in 1871, and though he was afterwards ambassador at London (1871-78) and Paris (1878-82), he never again took a prominent part in politics. He died October 24, 1886. See his *Memoirs* (Eng. trans., with an introduction by Baron Henry de Worms, 2 vols. 1887).

Beuthen, a town of Prussian Silesia, 121 miles SE. of Breslau by rail, close to the Polish frontier. It lies in a mining district, and has manufactures

of woollen cloths and earthenware. Pop. (1871) 17,942; (1890) 36,905.

Beveland. NORTH and SOUTH, two Dutch islands in the estuary of the Scheldt. South Beveland is the largest and most fertile of the Zeeland (q.v.) islands, and has a population of 23,000. North Beveland is low and marshy.

Bevelled-gear. See GEARING.

Beveren, a town of Belgium, in East Flanders. The principal industry is the making of point-lace. There is a noticeable church. Pop. 8637.

Beveridge. WILLIAM, Bishop of St Asaph, was born at Barrow, Leicestershire, in 1637, and entering St John's College, Cambridge, in 1653, as a sizar, devoted himself to the study of the classical and Semitic languages, on which latter he published a treatise at the age of twenty. In 1661, having obtained his degree of M.A., he was ordained both deacon and priest. After holding various preferments, in which he was remarkable for his devotion to his pastoral duties, he was, in 1704, appointed to the bishopric of St Asaph, having previously refused to accept that of Bath and Wells, on the deprivation of Dr Thomas Ken for not taking the oaths to the government of William III. He died 5th March 1708. His sermons and other works were published in 1824 (9 vols.); and there is another edition in the Library of Anglo-Catholic Theology (12 vols. 1842-46); but *Private Thoughts upon Religion* (1709) is his only work now read.

Beverland. ADRIAN, a Dutch scholar, who, by several of his writings, but more especially by his unorthodox interpretation of the Fall, caused great excitement among the theologians of his day. Born at Middelburg, in Zeeland, about the middle of the 17th century, he had studied law, visited Oxford University, and settled as an attorney in Holland, when, in 1678, he published his pamphlet, *Pecatum Originale*, which not only was burned at the Hague, but led to his own imprisonment, and to his expulsion from Utrecht and Leyden. On his return to the Hague, he wrote *De Stolte Virginittatis Jure* (1680), which gave still greater offence than his first work. Soon after, he came to England, where he found a supporter in Isaac Vossius. He became insane, and died in England soon after 1712. His works are now mere bibliographical curiosities.

Beverley, the chief town of the East Riding of Yorkshire, 1 mile W. of the river Hull, with which it communicates by canal, and 8 miles NNW. of the city of Hull. Its trade consists in corn and coal, and tanning and the manufacture of agricultural implements are the staple industries. The finest object in Beverley is the superb Gothic minster, or the Collegiate Church of St John, ranking next to York Minster among the ecclesiastical structures of the county, and exhibiting different styles of Gothic architecture, the oldest part being of the 13th century. It is 334 feet long and 167 across the transept; the western towers are 200 feet high. The choir contains the celebrated Percy shrine, of the most exquisite workmanship. The minster has been restored since 1867 by Sir G. G. Scott, by whom, too, was restored the fine cruciform church of St Mary. The 14th-century North Bar is the sole survivor of four old gates. The grammar-school of Beverley is so old that the date of its foundation is unknown. Beverley arose out of a priory founded by St John of Beverley, who was born at the neighbouring village of Cherry Burton, became Bishop of Hexham first, and then of York, and died in 721. The name is a corruption of *Beverlac*, 'lake of beavers.' Pop. (1851) 10,058; (1881) 11,442; (1891) 12,539.

Beverloo, a village of Belgium, in the province of Limbourg, 12 miles NW. of Hasselt. On the heath near is a permanent military camp. Pop. 1090.

Beverly, a town of Massachusetts, on an arm of the Atlantic, opposite Salem, with which it is connected by a bridge, and 18 miles NE. of Boston by rail. It has a good harbour, with fisheries, and manufactures shoes. Pop. (1890) 10,821.

Bevis of Hampton, the hero of a popular English medieval romance. The son of Sir Guy, Earl of Hamtoun, who was treacherously murdered by Divoun, emperor of Almayne, he was given by his false mother to some heathen merchants to be sold for a slave among the Paynim. By them he was carried to Ermony, where he soon became dear to King Ermyyn, and dearer still to his only daughter, the lovely Josian. His chief exploits were the overthrow of Brademond of Damascus, of a monstrous boar, of the giant Ascardap whom he spared to become his squire, and of a dreadful dragon near Cologne. His famous sword Morglay he won in battle; his horse Arundel was the gift of Josian. Still more romantic episodes in his story are his carrying his own death-warrant in a sealed letter to the vassal Brademond, his escape from his noisome dungeon after seven years' imprisonment, and recovery of his wife who had preserved his love, though nominally the wife of King Ynor of Mombraunt. He next returned to England to avenge his father's death, then sailed for Ermony and defeated Ynor in a desperate battle. His last great fight was in the streets of London, when he slaughtered sixty thousand citizens, and forced King Edgar to grant him terms. Thirty-three years he then spent in love and perfect happiness at Ermony, dying at the same moment as his wife, while his famous steed Arundel had died just before. The romance was edited by Dr E. Kölbing for the Early English Text Society in 1885.

Bewcastle, a village of East Cumberland, 10 miles NE. of Brampton. Pop. of parish, 800. A headless stone cross in the churchyard, 14½ feet high, bears an Anglo-Saxon runic inscription, which, as interpreted by Professor Stephens of Copenhagen, shows the cross to belong to the year 670. See RUNES, and *Trans. Cumberland Ant. Soc.* (1878).

Bewdley (formerly BEAULIEU, from its pleasant situation), a municipal borough on the right bank of the Severn, Worcestershire, 14 miles NNW. of Worcester, on the Severn Valley Railway. Till 1885 Bewdley returned one member to parliament. It has manufactures of leather, combs, malt, carpets, and iron and brass wares. Near the town is a public park of 400 acres. Bewdley in the 13th century had a right of sanctuary for those who had shed blood. Henry VII. built a palace at Bewdley for his son Arthur, married here by proxy to Catharine of Aragon. Pop. 2876.

Bewick. THOMAS, to whom the modern revival of the art of wood-engraving is mainly due, was born at Cherryburn, Ovingham, Northumberland, August 12, 1753. His father was a farmer and the lessee of a colliery, and during his early years he enjoyed the ordinary life of a country boy, greatly interested in field-sports, and laying the foundation of that knowledge of the face of nature and of the appearance and habits of her living creatures, which afterwards so strongly influenced his artistic productions. Soon he began to depict the things that he had seen, embellishing the margins of his school-books, and sketching with chalk on floors and on the flat stones of the churchyard. At the age of fourteen he was apprenticed to Ralph Beilby, a Newcastle engraver, who turned out work of the most miscellaneous description, and the first woodcuts that he produced were a

series of diagrams illustrating Dr Hutton's *Mensuration*, published in 1768-70. In 1776, after the expiry of his apprenticeship, Bewick settled as an engraver in London; but the ways of the metropolis were little to his taste, and in less than a year he returned to Newcastle. Soon after, he became the partner of his former master, and taking his brother John Bewick (born 1760, died 1795) as an apprentice, he executed, probably with his assistance, the woodcuts for an edition of *Select Fables*, published in 1784. Towards the close of the following year Bewick began to work upon the blocks of the animals and of the vignettes and tailpieces of his *History of Quadrupeds*, issued in 1790, which fully established his reputation as an engraver. They were mainly drawn and cut in the evenings, after the ordinary routine of the shop was ended; and the accompanying letterpress was compiled by his partner. During the progress of this work he executed in 1789 his 'Chillingham Bull,' a large woodcut, which some have regarded as his masterpiece.

The success of the *Quadrupeds* led to the publication of a similar *History of British Birds*, in which the artist's highest powers were manifested, and which, like his other great works, has appeared in numerous successive editions. The first volume, dealing with land-birds, was issued by the firm in 1797, and the second, on water-birds, in which he was aided by such talented pupils as Johnson and Clennell, was published by Bewick alone in 1804. The figures of the various birds are rendered with the utmost spirit and accuracy, and as examples of powerful and finely decorative arrangements of black and white, nothing could surpass his 'Eagle Owl,' his 'Short-eared Owl,' and his 'Goldfinch.' The tailpieces are vivid renderings of landscape and of rustic life, and are frequently touched with a homely and most vigorous humour. In technical method these illustrations show an immense advance upon all previous examples of wood-engraving. Self-taught, and working from his own designs, Bewick instinctively adopted such methods as were in truest harmony with the especial capabilities of his material, working with white lines into the lights, from the black tint given by the untouched block. Each touch of his graver is laid with intention and definite meaning; and while later engravers have far surpassed him in finesse and manual dexterity, and have produced on wood marvellous imitations of other styles of engraving and surprising transcripts of the tone and texture of brush-work, Bewick's cuts will always maintain their place as classic in their kind, as standard examples of right aims and true direction in wood-engraving. Numerous other works were produced by Bewick, but we need only mention the *Aesop's Fables*, published in 1818, upon which he was engaged for six years. In these illustrations he was assisted by William Temple and William Harvey, and by his son, Robert Elliott Bewick (born 1788, died 1849), who became his partner in 1812, and also took part in the cuts for an unfinished *History of British Fishes*, published in 1862 in his father's charming autobiography. This admirable artist and most estimable man died at Gateshead, November 8, 1828. Interesting collections of his water-colours, drawings, and woodcuts, the gift of his daughters, are in the British Museum and the Newcastle Natural History Library.

See Hugo's *Bewick Collector* (1866), and 'Supplement' (1868); *Life*, by Thomson (1882); *Bewick and his Pupils*, by Dobson (1884); and for an account of his technical method, Jackson and Chatto's *History of Wood-engraving* (1861; the first edition appeared in 1839), Linton's *Hints on Wood-engraving* (1879), and Hamerton's *Graphic Arts* (1882).

Bex, a village in the Swiss canton of Vaud, 26 miles SE. of Lausanne, with great salt-mines, salt-works, and sulphur-baths. Pop. 3958.

Bey. See **BEG.**

Beybars, or **BIBARS**, the Mameluke commander who in 1250 defeated St Louis at Damietta, became Sultan of Egypt in 1260, warred victoriously with Christians and Tatars, took Damascus and Antioch, and died at Damascus in 1277.

Beyerland, one of the island-districts of South Holland, and lying between the Maas and the Hollandsche Diep. It is 15 miles long.

Beyle, **MARIE-HENRI**, a French author, better known by his *nom de plume*, 'Stendhal,' born at Grenoble, 1783, was painter, government-clerk, soldier, and merchant by turns, and accompanied the fatal Russian campaign of 1812. After some years' residence in Milan, he returned in 1821 to Paris, where he acquired a high reputation as a *litterateur*. He was consul at Trieste and Civita Vecchia from 1830 to 1841, and died at Paris, March 23, 1842. Stendhal's keen powers of criticism and psychological analysis give greater value to his works on art and music than to his romances, although the same piquant style, brilliant wit, and wide knowledge of the world, appear in all his writings. His defects are a morbid straining after originality, and an ostentatious cynicism and contempt for moral sentiment. His best novels, which all lack consistency of plot, are *Le Rouge et le Noir* (1830) and *La Chartreuse de Parme* (1839). His principal critical works are *Histoire de la Peinture en Italie* (1817); *De l'Amour* (1822); *Racine et Shakespeare* (1823), which greatly aided the cause of romanticism; *Vie de Rossini* (1824); and *Promenades dans Rome* (1829).—See Paton's *Henry Beyle* (1874), and E. Rod's *Stendhal* (Paris, 1892).

Beypur, a seaport of Western India, in Malabar district, Madras, near the mouth of the Bepur River, 6 miles S. of Calicut. Iron ore and coal are found in the neighbourhood, and ironworks have been established here. Since 1858 Beypur has acquired importance as the terminus of a railway across the peninsula of India from Madras by way of Coimbatore, but is still a small place; pop. 6739.

Beyrout, or **BEIRÛT**, believed to be the *Berothai* or *Berothah* of the Old Testament (2 Sam. viii. 8 and Ezek. xlvii. 16); and known to the ancients under the name of *Berytus*, as a Phœnician seaport belonging to Sidon. In the 12th century it was for a few years in the hands of the Christians, and has since been subject successively to the Saracen, Seljuk, and Turkish sultans. In 1840-41 it was bombarded by the English fleet under Sir C. Napier, taken from the Egyptians, and delivered over to the Turks. Beyrout is a flourishing commercial town, situated in a most picturesque position on the coast of Syria, and at the foot of Lebanon, 55 miles from Damascus, and 147 from Jerusalem. It is the chief seaport, market-town, and emporium of all the trade with the shores of Syria, Palestine, and Cilicia, with a regular service of Egyptian, French, and British steamers. The latter bring Manchester goods, woollens, Rangoon rice, hides, copper, iron, and coal, and return to England with corn and silk. Since the opening of the Suez Canal, a direct eastern trade in spices, coffee, indigo, and jute has sprung up. The roadstead is full of sand-banks, and large ships cannot approach within half a mile of the shore, but shelter is found during stormy weather in the Beyrout River, about 3 miles from the town. Commerce has of late years very largely increased, the annual value of imports having risen in 1848-ss from £550,000 to about £1,800,000, and the

exports from a little over £200,000 to about £600,000. About half the total imports are from Great Britain. In 1886, 4009 vessels, with a burden of 618,699 tons, entered and cleared the port. Ship-building has received some attention. In 1859 a line of omnibuses, the first ever seen in Syria, was established here, and a French company completed in 1863 a good road to Damascus, of which Beyrout is the port; in 1875 an English company completed an extensive system of water-works, and in 1886 a concession for gas-works was sold to a Paris company. A Scottish school for Jews has been founded at Beyrout, as also the dépôt of the American-Syrian mission, with a school, printing-press, and medical staff. The population numbers some 80,000 (two-thirds of whom are Christians, and some 2000 Europeans) against 8000 in 1844. In 1890-95 a railway was made from Beyrout to Damascus.

Beyschlag. WILIBALD, a German evangelical theologian, born at Frankfurt in 1823, was appointed professor of Theology at Halle in 1860. His *Leben Jesu* (3d ed. 1893) and *Neutestamentliche Theologie* (trans. 1895) are standard works; others are: *Die Christologie des Neuen Testaments* (1866); *Die Paulinische Theodicee*, Rom. 9-11 (1868); *Die Christliche Gemeindevorstellung im Zeitalter des Neuen Testaments* (1874); and *Zur Johanneischen Frage* (1876). Since 1876 he has edited the *Deutsch-evangelische Blätter*.

Beza. THEODORE (properly De Bèze), next to Calvin the most active and influential of the Genevese reformers, was born of a noble family at Vezelai, in Burgundy, 24th June 1519. He received an admirable education at Orleans and at Bourges in the house of Melchior Volmar, a learned German, who taught him Greek, and also imbued him with the principles of the Reformation. As early as 1539, Beza became known as a writer of witty and elegant but indecent verses, the publication of which (1548) caused him many bitter regrets in after-days. After studying law at Orleans, he obtained his degree as licentiate of civil law in his twentieth year, and went to live in Paris, where he appears to have spent several years in fashionable dissipation. His handsome figure, together with his fine talents and good birth, opened to him the most brilliant prospects. It was the desire of his relatives that he should enter the church, but a private marriage which he had contracted rendered this impossible.

After a severe illness, during which the sinfulness of his career presented itself to his conscience, he went to Geneva along with his wife, October 1548. Shortly after, he was appointed Greek professor at Lausanne, an office which he held for ten years. In 1550 he published with success a drama, entitled *The Sacrifice of Abraham*, and delivered lectures to crowded audiences on the Epistle to the Romans and the Epistles of Peter. Out of these lectures ultimately grew his translation of the New Testament into Latin. In 1559 he went to Geneva, where he became Calvin's ablest coadjutor, and was appointed a theological professor and president of the college. He had already signalled himself by his work *De Hæreticis a Civili Magistratu Puniendis* (1554), in which, like many other honest but mistaken men, he approved of the burning of Servetus.

Beza was as skilful a diplomatist as a theologian. He induced the king of Navarre to exert his influence on behalf of the persecuted French Protestants, and was persuaded by the latter to attend the conference of Catholic and Protestant divines held at Poissy in 1561. Here his courage and dexterity made a very favourable impression on the French court. While in Paris he often preached before the king of Navarre and Condé. On the out-

break of the civil war he accompanied the latter as a kind of military chaplain, and after his capture attached himself to Coligny. In 1563 he once more returned to Geneva. The following year Calvin died, and the care of the Genevese church now fell principally upon Beza's shoulders. He presided over the synods of French reformers held at Rochelle in 1571 and at Nîmes in 1572. In 1574 he was deputed by Condé to transact important business at the court of the Palatinate; and in 1586 measured himself with the Würtemberg divines. After the death of his first wife in 1588, though verging on seventy, he married again. In 1597 his calumniators spread the extremely foolish report that he was dead and at the last hour had returned to the bosom of the church. The witty patriarch replied in a poem full of sparkling vigour. He died 13th October 1605, at the ripe age of 86. The works by which he is best known are his translation of the New Testament into Latin, and his *Histoire Ecclesiastique des Eglises Réformées de France, 1521-1563* (3 vols. Geneva, 1580). There are lives by Schlosser (1809), Baum (1851), and Heppe (1861).

Bezants', or BYZANTINES, are coins of the Byzantine empire. The gold bezant varied in value at different times from a sovereign to half a sovereign; the silver one from a florin to a shilling; are of gold and silver; bear impressions distinct from those of the earlier Roman coins; and were copied in several countries where the Byzantine standard was adopted. The commercial relations of the Eastern empire served to distribute its coinage over almost all the then known world. It was current in India as well as in England till the reign of Edward III. (see NUMISMATICS). Bezants were brought home by the Crusaders, and hence are of frequent occurrence as heraldic charges. Similar figures, when not coloured or (gold), or *argent* (silver), are known in heraldry by the general term of *roundels*. A *bezanty cross* is a cross composed of bezants.

Bezdan, a market-town in the Hungarian province of Bacs, and a station for steamships, on the canal joining the Theiss and the Danube, from which latter river it is about 3 miles distant. Much hemp is grown. Pop. 8366.

Béziers, a town in the French department of Hérault, is pleasantly situated on a hill in the midst of a fertile country, at the junction of the Orb and the Canal du Midi, 49 miles SW. of Montpellier by rail. It contains some interesting architectural buildings, the principal being the cathedral, a noble Gothic edifice, and the ancient episcopal palace; and antiquarian remains dating from before the time of the Romans. Béziers has manufactures of silk stockings, woollens, gloves, parchment, glass, soap, leather, brandy, and much esteemed confectionery. Pop. (1871) 31,468; (1891) 42,436. In 1209 the inhabitants were indiscriminately put to the sword by Simon de Montfort and the pope's legate for having afforded protection to the Albigensian fugitives.

Bézique (also called *Besique*), a game at cards, played with a double pack, in which the objects are principally to promote in the hand certain combinations which, when 'declared,' entitle the holder to score, and to win certain cards of a particular value. There are practically no restrictions in the game; it is not necessary to follow suit; and two, three, or four players may engage in it.

Be'zoar (through Fr. and Span. from Persian *pūd-zahr*, 'counter-poison,' *zahr*, 'poison'), a concretion found in the stomachs of goats or antelopes, and formerly much valued on account of imaginary medicinal virtues, particularly as an antidote to

poisons. Concretions of various kinds are found in the stomachs of herbivorous quadrupeds, very generally having for their nucleus some small indigestible substance which has been taken into the stomach. Sometimes they are of a radiating structure; sometimes formed of concentric layers; sometimes they are principally composed of superphosphate of lime; sometimes of phosphate of ammonia or of magnesia. Other concretions found in the intestines, &c. of various animals are sometimes also called bezoar (see CALCULUS). The value of a bezoar being supposed to increase with its size, the larger ones have been sold, particularly in India, for very great prices.

Bhagalpur, or BOGALIPOOR, a town of Bengal, stands on the right bank of the Ganges, here 7 miles wide, and by rail is 265 miles NW. of Calcutta. Pop. (1891) 69,106. The long, narrow district of Bhagalpur, lying S. of Nepaul, has an area of 4226 sq. m., and is divided into two nearly equal portions by the Ganges. The lowlands are fertile and well cultivated. Indigo is the chief manufacture, and rice and other cereals are the principal articles of export. Of the population (over two millions) 90 per cent. are Hindus.—The *division* of Bhagalpur comprises five districts.

Bhagavad Gītā ('The Song of the Adorable') is the title of a lengthy theosophical poem which has been incorporated in the great Indian epic, the Mahābhārata, although it is clearly of later date than the rest of that work, its composition being usually assigned to the first or second century after Christ. The leading theme of the poem is the exaltation of the god Vishnu in his human form or avatar of Krishna, and throughout it the god speaks in his own person. In this incarnation Vishnu became the charioteer of Arjuna, a chief of the Pāndus, who were then at war with their kinsmen, the Kūrus. On the eve of a battle, when Arjuna is appalled at the thought of slaughtering his own kindred, Krishna sets before him the duties demanded of him as a member of the warrior caste, and at the same time propounds an eclectic system of philosophy of an ethical pantheistic type, laying especial emphasis on the doctrine of *bhakti*, or faith in the Supreme Being, whom he declares himself to be. The poem is divided into three sections, each containing six chapters, called *upaniṣads* ('secret doctrine'), a name which shows the mystical character of the work. In the *first* section, the duties and observances of caste are directly inculcated, and asserted to be entirely in harmony with the principles of the Yoga philosophy—viz. asceticism and meditation, by which absorption in the Deity, the highest object of humanity, is attained. In the *second*, the pantheistic doctrines of the Vedānta philosophy are expounded and taught. In the *third*, the pantheism of the Vedānta is interwoven with the dualism of the Sāṅkhya philosophy. The remarkable similarity existing between many of the ideas and expressions of the poem and those of the New Testament has led some scholars—e.g. Weber, Lorinser, and Nève—to infer an actual borrowing from the latter. This theory has, however, been vigorously combated by Telang, and is still *sub judice*.

The Bhagavad Gītā has been edited by Schlegel (Bonn, 1846), with a Latin translation, and by Thompson (Hertford, 1855). It has been translated into English by Wilkins (1785), Thompson (1855), Davies (1882), Telang (Bombay, 1875), and by the same in 'Sacred Books of the East,' vol. viii., and Chatterji (1887); also into German, French, and modern Greek, as well as into most of the modern Indian languages. The philosophy of the Bhagavad Gītā has been discussed by W. von Humboldt in

a special treatise (1827), and commented on by Chintamon (1874).

Bhagirathi, a branch of the Ganges, regarded as sacred by the Hindus, leaves the Ganges at Chhapghati, divides the Murshidabad district into two portions, forms the boundary line between Nadiya and Bardwan districts, and joins the Jalangi at Nadiya town to form the Hooghly (q.v.).—Also the name of a head-stream of the Ganges, rising in Gangotri Peak, Garhwal, North-west Provinces, which joins the Alaknanda at Deoprayag, and is afterwards known as the Ganges.

Bhamo, a town of Burmah, is at the head of the navigation of the Upper Irawadi, 40 miles to the west of the Chinese frontier, and 300 miles from Mandalay. It has long been a mart of Burmese trade with China; and attention has been directed to it, especially since the annexation of Upper Burmah by Britain, as an important centre for the development of trade between India and China through Western Yunnan, along the trade routes to the eastward. These prospects have been greatly promoted by the Anglo-Chinese agreement of 1893, and the establishment of a British Consul at Manwyne in Yunnan. The chief goods exported to Yunnan are ornamental feathers, serpentine, amber (for official buttons), English cottons, and other cloths. The trade is mainly in Chinese hands. Steamers ply to Rangoon, and a railway has been projected. Pop. 6986, Burmans, Shans, and Chinese.

Bhandara, capital of a district in the Central Provinces, 40 miles E. of Nagpur; pop. 11,150.

Bhang, the native name for the Indian variety of hemp (q.v.) and Hashish (q.v.).

Bhanpura, a walled town of Central India, in Indore state, on the Rewa, 60 miles S. of Kotah. Pop. 13,400.

Bhartpur, or BHURTPORE, the capital of a protected state in Rajputana, is a large town, measuring about 8 miles in circuit, 35 miles W. of Agra by rail. It is worthy of notice chiefly on account of its two sieges in 1805 and 1827. The strength of the place lay in a mud wall, which was practically shot-proof, and a surrounding ditch, which baffled four successive assaults by Lord Lake. On the second occasion, however, Lord Combermere carried the fortress by mining. Pop. (1891) 68,033.—The state of Bhartpur has an area of 1974 sq. m.; pop. 640,303, mostly Jāts. It suffers from want of water, having only one river flowing through it; and yet, in many parts, the soil is rendered highly productive by means of irrigation. The revenue of the state is more than £300,000 a year; and the total military force amounts to 10,000 men of all arms.

Bhartrihari is the name of a celebrated Indian writer of apothegms, of whom but little is known. A legendary story makes him the brother of King Vikramāditya, who lived about the middle of the 1st century B.C., and relates of him, that after a wild licentious youth, he betook himself in later years to the ascetic life of a hermit. His name has been given to a collection of 300 apothegms, arranged in three centuries or groups of a hundred (*cataka*), but it is likely that these were the work of various authors, but ascribed, according to the Indian custom, to a well-known name. Cheerful descriptions from nature, and charming pictures of love, alternate in these apothegms, with wise remarks upon the relations of life, and profound thoughts upon the Deity and the immortality of the soul. Bollen published an excellent critical edition (2 vols. Berlin, 1833-50), as well as a successful metrical translation into German (Hamburg,

1835). Bhartrihari has a special interest as the first Indian author known in Europe, 200 of his apothegms having been translated by the missionary, Abraham Roger, in a learned work published at Nuremberg in 1653, under the quaint title, *Offene Thür zum verborgenen Heidentum*.

Bhatgaon, a town of Nepaul, 8 miles SE. of Khatmandu. It is the favourite residence of the Brahmans of Nepaul. Estimated pop. 30,000.

Bhaunagar (*Bhāvanagar*), capital of a Bombay native state, on the Gulf of Cambay, 60 miles NW. of Surat; pop. 57,653. Area of state, 2860 sq. m.; pop. 400,323.

Bhavabhūti, surnamed 'Sri-kantha,' a great Indian dramatist, who flourished in the first half of the 8th century, and wrote three plays and a domestic drama (see SANSKRIT, Vol. IX. p. 152). Bhavabhūti is often compared with Kālidāsa, whom he equalled in vigour and variety, but hardly in genius. All three plays have been translated into English.

Bhel, or BAEI. See ÆGLE.

Bhils, a pre-Aryan race of Central India, inhabiting the states from the Khandesh district of Bombay to the wild hilly tracts of the Vindhya range, north of the Nerbudda River. In 1825 James Onram organised a Bhil corps in order to utilise the warlike instincts of the people, and at the same time the first Bhil agency was formed. The Bhils are dark, diminutive men, brave and active, but predatory and superstitious. Their normal habit of life has been nomadic, wandering about with their sheep and goats, and living chiefly on game and fruit. At present some faint progress has been made in civilising them, and a very few have been brought to till the ground. They number some 750,000.

Bhilsa, a town of India, in Gwalior state, on the Betwa, 26 miles NE. of Bhopal. At Sanchi, near Bhilsa, is the most remarkable group of topes (see TOPE) in India. See Maisey's *Sanchi and its Remains* (1893). Pop. 7070.

Bhiwani, a town of the Punjab, 37 miles SE. of Hissar by rail. It is the chief commercial centre of the district, and a brisk trade is done in sugar, salt, spices, and metals. Pop. 35,487.

Bhopal, the capital of a native state in Central India, 325 miles SW. of Allahabad. The largest of two artificial lakes in the neighbourhood measures $4\frac{1}{2}$ miles by $1\frac{1}{2}$.—The state of Bhopal has an area of 6874 sq. m. Though the vast mass of the people are Hindus, yet the government is Mohammedan, and Bhopal has the reputation of being the best-governed native state in India. The state was founded in 1723 by Dost Mohammed Khan, and a treaty of dependence was concluded between the ruler and the British government in 1818. Shah Jahān, the Begum of Bhopal, in 1872 received the Grand Cross of the Star of India. Pop. of state (1891) 952,986; of city, 70,338.

Bhuj, the capital of the Indian native state of Cutch, 180 miles SE. of Hyderabad. Its mosques and pagodas, interspersed with plantations of dates, give to the town an imposing appearance from a distance. Pop. 25,421.

Bhurtপুর. See BHARTPUR.

Bhutan, an independent state in the eastern Himalayas, bounded on the N. by Tibet, S. and E. by Assam, and on the W. by Sikkim. It is divided into East and West Bhutan; and before the British annexation in 1841 and 1865 of the eighteen *Dwars* or passes which lead from the plains to the lofty terraces of Bhutan, the area was estimated at 20,000 sq. m.; since, it has been estimated at 15,000 sq. m. With summits exceeding 24,000 feet, the whole surface may be

described as mountainous, abounding in sublime and romantic scenery, with a gradual slope from north to south. Generally speaking, the middle ranges are the most productive. While the south presents but a scanty vegetation, and the north rises far above the limit of perpetual snow, the central regions, at an elevation of 8000 or 10,000 feet above the sea, are covered with the finest forests of oak and pine, with beech, ash, birch, and maple. Amongst wild animals, elephants are numerous, and leopards, deer, wild hogs, bears, and the rhinoceros are also found. The Manās, a tributary of the Brahmaputra, is the most considerable river. Turnips grow well, and nearly all sorts of grain—wheat, barley, rice, maize, and buckwheat—are here and there cultivated on terraces cut out of the sides of the hills. The foreign trade, which consisted in the exchange of commodities in return for native cloths, rock-salt, rhubarb, Tibet goods, mules, and the famous Tangastan horses or ponies, has declined. The nominal religion is Buddhism, but amongst the common people this goes little further than the recital of a few sacred sentences, and the propitiation of evil spirits. The government, almost purely ecclesiastical, is in the hands of a rapacious oligarchy. The Dharm Rajah, the nominal head, is treated rather as a god than as a sovereign; while the Deb Rajah, the actual head, is elected every three years by the chiefs from amongst themselves. They are controlled by the Lenehen or council of ministers. Polygamy and polyandry are common. The lower orders are dirty in their persons and habits; their food consists mostly of pork, turnips, rice, barley-meal, and brick-tea. They are neat joiners, and their houses of three and four stories have the appearance of Swiss chalets, but are without chimneys. The winter capital is Punakha on the Bugui River, 96 miles NE. of Darjeeling. The summer capital is Tasichozong (Tassisdon), on the Gudada River, a centre of Lamaism. The original inhabitants, believed to be from Kuch Behar, were called Tephu; they were subdued by a band of Tibetan soldiers 200 years ago, who settled in Bhutan. The Bhutias speak a dialect of Tibetan. In 1772 the rajah of Kuch Behar received assistance from the British government against their invasions. Later raids led to the treaty of 1865, when the eighteen *Dwars* or passes of Bengal and Assam were ceded to the British government in return for a yearly subvention. The population of the state, formerly estimated at from 20,000, seems to be much larger—possibly 200,000.

Biafra, BIGHT OF, a large bay on the west coast of Africa, at the head of the Gulf of Guinea, between Capes Formosa and Lopez. The principal rivers flowing into it are the Niger (q.v.), the New and Old Calabar rivers, the Rio del Rey, the Cameroon, and the Gaboon; its islands are Fernando Po (Spanish), and St Thomas' and Prince's Islands (Portuguese). Opposite Fernando Po are the Cameroons (q.v.).

Bialystok, a town in the Russian government of Grodno, on the Biala, 55 miles W. by S. of Moscow by rail. Its castle is now used as a convent, but formerly belonged to the Counts of Braniski, and was called the 'Versailles of Poland.' More than thirty factories produce cloth and woollen stuffs. Pop. 56,611.

Biana. See BAYANA.

Biancavilla, a town of Sicily, on the southwest declivity of Mount Etna, 24 miles NW. of Catania. It has a trade in grain, cotton, and silk. Pop. 13,021.

Bianchini, FRANCESCO, antiquary and astronomer, was born in 1662 at Verona. At Padua he

studied theology, mathematics, and botany; and in 1684 proceeded to Rome, where he became intimate with the most distinguished *savants* of the day, and devoted himself to the study of jurisprudence and foreign languages. Alexander VIII. bestowed upon him a rich benefice, and Clement XI. appointed him secretary to the commission for reforming the calendar. He died in Rome in 1729. He was author of various works, but is chiefly remembered in connection with the Meridian Line (q.v.).

Bianconi. CHARLES, born in Lombardy in 1786, came at the beginning of the century to Ireland as an itinerant vendor of cheap prints. Having accumulated a small capital, he started the first public conveyance between Clonmel and Cahir in 1815, at a time when the peace and the carriage-tax had filled the market with cheap horses and jaunting-cars. The enterprise succeeded, until, 40 years after, Bianconi's cars were working over 4000 miles of road daily. Having realised a large fortune, he retired in 1865, and died in September 1875, at his estate near Cashel. He was a devoted adherent of O'Connell, into whose family both his son and daughter married.

Biard. AUGUSTE FRANÇOIS, a *genre* painter, born at Lyons in 1798, travelled in early life in the Levant, in 1839 visited Greenland and Spitzbergen, in 1858-59 Brazil, and in 1865 travelled round the world. Among his best pictures are the 'Beggar's Family,' 'African Slave-market,' 'Fight with Polar Bears,' and 'The Wandering Comedians.' He died in Paris, June 1882. His wife, Leonie d'Annet (1820-79), separated from him since 1845, was author of some novels, a play, &c.

Biarritz. a favourite watering-place in the French department of Basses-Pyrénées, on the Bay of Biscay, 6 miles SW. of Bayonne. Here, in 1855, Louis Napoleon built the Villa Eugénie for the empress, who already, as Countess de Tula, had been a frequent visitor. The presence of the court combined with the pleasant situation and salubrity of the place to increase greatly the fame of its baths and its caverned cliffs. During the season (July-September) the place is often visited by 6000 guests, for whose accommodation have been built several good hotels, a number of scattered villas, a casino, a large bathing establishment, an English Protestant church, &c. Pop. 7159. See, besides the guidebooks, De Lavigne, *Biarritz* (Paris, 1882); Count Russell, *Biarritz and the Basque Country* (Lond. 1873).

Bias, one of the Seven Wise Men of Greece, a native of Priène in Ionia, flourished about the middle of the 6th century B.C., famous for his eloquence, his nobility of character, and his apothegms. Among these perhaps the best were: 'Know and then act,' 'He is unfortunate who cannot bear misfortune,' 'So order your affairs as if your life were to be both long and short,' and that addressed to the irreligious sailors who during a storm were loudly calling on the gods, 'Be quiet, lest the gods discover that you are here.' Once when his fellow-townsmen in alarm before an enemy were hastily carrying off their valuables, Bias was seen without a burden, and being asked why he was not occupied like others, replied in words which have become a Latin proverb, *Omnia mea mecum porto*, 'I carry all my goods with me.'

Bias. See BEAS.

Bias. See BOWLS.

Bib. also called BRASSY, POUT, or WHITING POUT (*Gadus luscus*), a fish of the same genus as the Cod, Haddock (q.v.), and Whiting, pretty common on many parts of the British coasts, found also on those of Norway, Sweden, Greenland, &c. It is

seldom more than a foot long, but differs from the other British *Gadidae* in the great depth of its body, which equals at least one-fourth of the entire length. The back is arched, and the nape exhibits a rather sharp ridge. The head is invested with a loose dilatable membrane. The names Bib and Pout, both originally local English names, were at one time supposed to refer to distinct species (*G. lusca* and *G. barbata*), but these, probably, are really one.

Biberach, a town of Württemberg, delightfully situated on the Reiss, 23 miles SSW. of Ulm. It retains its old ramparts and towers, and in front of the theatre is a monument to Wieland, who was born in the neighbourhood. There are manufactures of machinery, artificial flowers, leather, bells, children's toys, &c. Pop. 8264. In 1796 Moreau won a great victory over the Austrian general Latour at Biberach, the latter losing 4000 prisoners. Here also, in 1800, Saint Cyr defeated the Austrian general Cray. Biberach fell into the possession of Baden in 1802, but four years afterwards was ceded to Württemberg.

Biberich. See BIEBRICH.

Bib'iri and Bib'irine. See GREENHEART.

Bible. The Bible is in Gr. *Ta Biblia*, 'The Books,' *par excellence*. Though a plural in Greek, the word came, on account of its termination, to be used in Low Latin as a feminine singular; and from the Latin it passed in this form into modern languages (*la Bible*, *die Bibel*, and the like). The Bible consists of two great parts—the Old and New Testaments, properly Covenants. The religion of Israel was considered a covenant between Jehovah, their God, and the people. As this covenant had proved ineffectual for its purposes, the prophets promised a *new* covenant (Jer. xxxi. 31); and in the appearance and death of Christ this new covenant was established (1 Cor. xi. 25; Heb. viii. 7 *seq.*, and, according to some readings, in the Gospels—e.g. Matt. xxvi. 28). As early as the 2d century of our era the books of the Old and New Covenants are spoken of, and as the Greek 'covenant' was rendered by the Latin *testamentum* (though some preferred *instrumentum*), the phrase Old and New Testaments passed into most modern languages, as into our own.

THE OLD TESTAMENT.—The literature of Israel is very closely connected with its history. As in all ancient states, the religion was national. The religious unit or subject was not the individual in the state; but the ideal unity formed by the people as a whole. Now this unity came into existence at the exodus from Egypt. From that hour Israel was conscious of being a people, and Jehovah who had delivered them was their God alone—'I am Jehovah thy God, who brought thee out of the land of Egypt' (Ex. xx. 2; Hosea, xiii. 4). The sense of being a people, and the sense of being the people of Jehovah, if not identical feelings, reacted very powerfully on one another; and hence the religious literature of the people reflects from age to age all the changing hues of its history. That history ran very much such a course as we should have expected.

(1) The migration of the ancestors of the people from the East, the descent into Egypt, the oppression there, and the delivery under Moses, are events testified to not only in the formal history of the Pentateuch, but by frequent incidental allusions in other writers. These allusions express the fundamental historical feeling of the people, the very basis of their national and religious consciousness. (Amos, ii. 9 *seq.*; Hosea, xii. 13; Micah, vi. 4).

(2) It was natural that the unity into which the tribes had been welded at the Exodus by the necessity of facing a common danger or sharing a

common enterprise would become relaxed when the danger was over and the enterprise had in great measure succeeded; and, accordingly, after the settlement in Canaan we find the unity in some degree disintegrated, and the various tribes fighting each for its own hand, and only entering into combinations when some danger more serious than usual threatened. Such is the history as reflected in the Book of Judges. Even in this troubled period, although practically the tribes are often seen acting independently and settling with a strong hand their own local differences with the native population, the sense of the ideal unity of all the tribes as one 'Israel' inspires the higher minds in the nation (Judges, v. 2, 3, 5, 7, 9, &c.); and the need of some single head, such as a king, to represent this unity is often felt and expressed by the people (Judges, viii. 22).

(3) When a danger so pressing that it threatened the national existence of Israel arose in the Philistine power, the need of a visible head to bind the tribes together and lead them against the common enemy was universally recognised, and the people demanded that Samuel should give them a king 'to go out before us and fight our battles' (1 Sam. viii. 20). The aged seer, though reluctant to see the ideal sovereignty of Jehovah, the sense of which should have been enough to secure the national unity, brought down and materialised in the form of an earthly representative king, was sagacious and patriotic enough to perceive the necessities of the time, and to take them under his direction. And thus arose the monarchy, a partial attempt in the same direction having already been made by Abimelech (Judges, ix.). The history of this period is recorded in the Books of Samuel and in the early part of the Kings. This period is of intrinsic importance in the literary and religious history of Israel. Three powerful streams of influence issue from it, and run through the whole succeeding history, fertilising and enriching it. These were, first, the prophetic order, a class of men who probably existed from the earliest times along with the Nazirites (Amos, ii. 11), but who acquired an influence in the state at this period, first as counsellors and seers of the early kings (Nathan, Gad, 2 Sam. xii. 1, xxiv. 11), and ultimately as an independent order who took the religious destinies of the nation into their own hand, and in whose writings, the prophetic Scriptures, we have the fullest exposition of that lofty spiritual religion in Israel to which the New Testament directly attaches itself. Secondly, the elevation of the Davidic dynasty to the throne. The brilliant reign of David, whose arms extended the limits of the Jewish state, till for those days it might justly be named an empire, became the ideal of after-ages; and when amidst disaster and religious decline men looked back to it and transfigured it in the light of the religious hopes which filled their minds, it became the type both of a future king and a future universal kingdom of God that would arise upon the earth in the latter days. Thus arose those special predictions of the perfection of the kingdom of the Lord called Messianic prophecies. And thirdly, the choice of Jerusalem as the centre both of the national and religious life of the people. The influence of the temple of Solomon both in purifying and elevating the ritual worship, as well as in leading ultimately to its concentration at one shrine, can hardly be overestimated. But the step gave a colour to all the succeeding literature. Patriotism and religion were once more wedded together. Jerusalem was not only the perfection of beauty, the joy of the whole earth (Ps. xlviii. 2), it was also the 'hearth' of Jehovah, who dwelt in Zion at Jerusalem (Is. xxix. 1). National sentiment mingled with re-

ligious emotion in one powerful stream, and the union has given to the religious poetry of Israel which celebrates 'Zion,' or longs to revisit it, or tells that its dust is dear, not only a religious value but a never-dying human charm.

(4) There had always existed a jealousy between the North and South, between the powerful tribe of Ephraim, which always aspired to the leadership of the tribes, and the great tribe of Judah, and very naturally the unity of the tribes under the monarchy, when subjected to a severe strain under Rehoboam, broke asunder, and two kingdoms arose and existed side by side, sometimes hostile to one another but in the main friendly. Though either of the two kingdoms might prove itself sufficiently strong to hold in subjection the petty kingdoms of Edom and Moab, and even to maintain its own against the more powerful state of Syria, when confronted with the imposing empires of Assyria and Babylon they naturally lost their independence, first Israel at the hands of Assyria (721 B.C.), and then Judah at the hands of Babylon (586 B.C.), and became merged in these empires as provinces. The external history of the two kingdoms is told in the Books of Kings; and the internal condition of the people, the relaxation of morals, the struggles of contending parties, and the cruel idolatries to which despair had recourse, are reflected in the pages of the prophets—in the writings of Amos and Hosea during the last years of Samaria; in Isaiah and Micah during the conflict of the South with Assyria; and in Jeremiah during the death-struggle of Judah with Babylon.

(5) As one colossal empire followed another and succeeded to the inheritance of its predecessor—Babylon, Persia, Greece, and Rome—the people of Israel, no longer independent, existed as a community, governed internally in the main in accordance with its own conceptions, but forming externally part of the heathen empire for the time. Only after a successful revolt against the Greco-Syrian rule of the Seleucids did the people again attain to independence and become ruled by native princes for about a century (167–65 B.C.). It then fell under the influence of Rome, which finally destroyed the city and temple (70 A.D.). No external history of the Exile has been written; but the picture of the desolation of the land, the sad silence in the streets and gates of Jerusalem, which used to ring with the joy of the feasts, and the sense of abasement and contempt into which the people had fallen as a nation among the nations, together with the flickerings of a faith in the sure mercies of the Lord that refused to be quenched (Lam. iii.), may be seen in the exquisite collection of elegies called the Lamentations, written not many years after the fall of the city; while the delirium of hope raised somewhat later by the victories of Cyrus and the approaching downfall of Babylon, and the gorgeous anticipations of the destruction of idolatry and the conversion of the nations to the true religion of Jehovah through the ministrations of Israel restored, 'the servant of the Lord,' fill the pages of the second half of Isaiah (xl.–xli.). The fortunes of the returning exiles are described in Ezra and Nehemiah, and in the three prophets of the return (Zechariah, Haggai, Malachi), while the aims and faith and hopes of godly Israel during the Maccabean struggles are reflected in the Book of Daniel. Thus, amidst all the vicissitudes of its eventful history, the literary activity of Israel knew no intermission. The great literary period extends from 800 to 400 B.C., but much of the finest historical writing is anterior to this period, and several important books, as Chronicles, Ecclesiastes, and Daniel, fall later.

The threefold division of the Old Testament into

the Law, the Prophets, and the miscellaneous Writings is already known to the translator of Ecclesiastius (131 B.C.), and is found in the New Testament as the Law and the Prophets (Matt. xxii. 40), or Moses and the Prophets (Luke, xvi. 29), or more fully the Law of Moses, and the Prophets, and the Psalms (Luke, xxiv. 44). The date of the Law has been the subject of great difference of opinion; the period at which most of the prophets lived is well ascertained, and the *Prophetical Writings* may be referred to first.

The prophets Samuel, Elijah, and Elisha have left no writings: the same is true of Jonah, our present Book of Jonah being merely an historical episode in the life of that prophet. The oldest written prophecy is probably that of Amos, after whom the succession is continuous. The prophetic call was scarcely a call to an office; there was no prophetic as there was a priestly office. The prophet was a man who felt called of God and inspired to direct for the time being the religious destinies of the people and the kingdom of God. The prophets express the idea of their inspiration by various symbols: a cherub touches the lips of Isaiah with a live coal from the altar, and his sin is taken away (Is. vi.); the hand of the Lord himself touches the mouth of Jeremiah (Jer. i. 9), while Ezekiel is commanded to eat the roll of a book (Ezek. iii. 1). The essential idea of Hebrew prophecy is that in it God spoke directly to the mind and in the mind of the individual. This makes it a thing unique in the religious history of mankind. Other methods of reaching to knowledge of the will of God were divination or augury, not prophecy, and were proscribed. Several definitions of a prophet are given: according to the Pentateuch he is the spokesman of the Lord (Ex. vii. 1). Amos says (iii. 7) 'the Lord doeth nothing without revealing his counsel to his servants the prophets; the Lord God speaks, who can but prophesy?' Such a definition implies that *prediction* of future events was but a small element in the work of the prophet. The prophet was above all things a man of his own present time, raised up to interpret the events of providence, and guide the nation over the coming crisis. No doubt the most effectual guidance that could be given would many times be to open up glimpses of the future. Such glimpses are opened up by all the prophets, every one of whom sketches the history of the kingdom of God to its final perfection. Such an outlook into the future was absolutely necessary, if the people were intelligently to strive after the desired goal. The definition given by Amos suggests that the prophet will arise only when God is about to do some great work. And we find it to be so; it is in great national crises that the prophets appear—Amos and Hosea before the fall of Samaria; Isaiah during the great Assyrian struggle; Jeremiah before the destruction of Jerusalem; and the author of Isaiah xl. *seq.* just before the Restoration. The prophets then interpret the events of providence, and prophecy might almost be called the religious philosophy of history. The spirit of prophecy is not an arbitrary or unaccountable inspiration; it is the spirit of the covenant religion. The prophets are the bearers of the idea of the kingdom of the Lord. This idea is expressed in the two tables of the decalogue.

The history of the Judges shows us that Israel did not exterminate or drive out the native populations, but absorbed them. The consequence was both a corruption of morals and a debasement of the forms of worship, for probably too many in Israel itself stood on a religious level not greatly higher than that of the Canaanites. The higher spirit of the religion thus absorbed a mass of material which it was unable for long to

assimilate. Hence a struggle between the higher religious spirit and the lower elements of life and thought in the nation runs through its whole history. The prophets are the exponents of the higher ideas, which consist in the main of two principles: (1) that Jehovah alone is God of Israel, a practical doctrine which really meant that he was God alone; and (2) that he was a moral and spiritual being, who could be worshipped truly only in spirit. These two principles came into conflict with the tendency to idolatry among the people, and to a union of other deities with Jehovah; and with the sensuousness of their religious conceptions, of which the calf-worship was a result. The prophetic teaching is really little but a teaching regarding the nature of Jehovah, God of Israel; but because he is God of Israel, teaching regarding him reflects immediately back upon the people, who, to be his people, must be like him. Religion with the prophets is the source and the type of morals.

As the prophets are practical teachers for their own time, and have an immediate moral purpose in view, they deal with all the great forces, whether moral or political, of their day. They are statesmen in the Kingdom of God, and the figures that stand in their pages are those that bulked largely in their time, whether at home or abroad. The prophets of the Assyrian age occupy themselves with Assyria, those of the Babylonian age with Babylon. Hence the allusions in any prophecy furnish a criterion for fixing the age to which the author belongs. When, for example, we read in the second half of Isaiah that Cyrus shall let go the captives and rebuild the city of the Lord (xlv. 13), and find exhortations to the people such as this: 'Go ye forth of Babylon, flee ye from the Chaldeans: say ye, The Lord hath redeemed his servant Jacob' (xlviii. 20), the natural inference is, that the author lived during the exile and shortly before the fall of Babylon before Cyrus.

The Jewish division of the Prophets is into the former prophets and the latter prophets. The 'former prophets' are the historical books—Joshua, Judges, Samuel, and Kings. The 'latter prophets' are the prophets properly so called. These again are divided into the greater prophets—Isaiah, Jeremiah, and Ezekiel; and the minor, the twelve smaller books. The historical division is more instructive: (1) prophets of the Assyrian age—Amos, Hosea, Isaiah (740–700), Micah, Nahum, Zephaniah; (2) prophets of the Babylonian age—Habakkuk, Jeremiah (626–580), Ezekiel (593–576); (3) prophets of the Exile and Restoration—Isaiah, xl–lxvi. (550), Haggai and Zechariah (520), Malachi (420). The age of Joel and Obadiah is uncertain; while Jonah is late.

The Law and Historical Books.—When Moses is spoken of in the Prophets he is called a prophet (Hosea, xii. 13), and similarly in Deuteronomy (xviii. 15; xxxiv. 10). This is in conformity with the larger definition of a prophet as 'one who speaks from God.' The whole development of the religion of Israel implies that the people were not left by their leader without the knowledge of distinct and lofty moral and religious principles. Moses was also of the family which became the priestly caste in Israel, and it is quite improbable that the people were left destitute of instructions regarding the ritual service of their God. At the same time, it is scarcely to be supposed that the mass of minute and highly developed ritual ordinances in the Pentateuch came in their present form from Moses's hand. There has existed for long, and continues, great difference of opinion in regard to the origin of the Pentateuch, or rather Hexateuch, for the Book of Joshua, which contained a history of Israel's fortunes down to their

settlement in Canaan, originally belonged to the work.

Two points deserve notice—first, the analysis of the Pentateuch into its primary elements; and secondly, the relative age of these elements. It was early noticed that there were elements in the Pentateuch posterior to the Mosaic age, as the statement, 'these are the kings that reigned over the land of Edom before there reigned any king over the children of Israel' (Gen. xxxvi. 31). Double narratives also were noticed, as of Creation (Gen. i.-ii. 4, and ii. 5 *seq.*), and of the Flood. Differences of phraseology also characterised the different passages, and upon the whole there appeared one series of passages similar in tone and thought to the prophetic writings, while another betrayed the tone and interests of the priesthood. These general observations had been made when Astruc, a Belgian physician (1753), pointed out that the former class of passages used the name Jehovah, while the latter employed God (Elohim). With this discovery the passage (Ex. vi. 3) seemed to agree, which indicates that the name Jehovah came into special prominence at the Exodus. It was therefore assumed that one writer refrained from the use of the name Jehovah till he reached the period of the Exodus, using Elohim, while the other employed Jehovah from the beginning of his history. According to this and other distinctions, Genesis and the Pentateuch fell into two great divisions, called, after the divine names employed, Elohist and Jehovist sources. It was taken for granted that the division using the name 'God' was primary; it began with Gen. i., and hence was named the fundamental writing. And the next step was the natural assumption that the passages using Jehovah were supplementary, and inserted in the primary document by their author. And thus arose the theory known as the 'Supplement-hypothesis,' which long prevailed. In 1853, however, Hupfeld expressed the opinion that there was a second writing that used 'God,' and that both this writing and that using 'Jehovah' were not supplements to the first writing, but originally independent compositions. This view was generally accepted, but the state of opinion was hardly altered by it. The two smaller documents, though originally independent, had been united together, and in this united condition embodied in the great primary document. This primary document, now called the Priestly Code, consisted roughly of Gen. i.-ii. 4, v. xvii. xxiii. and many other small pieces, Ex. xxv.-xxxii. xxxv.-xl., all Leviticus, and great part of Numbers. The rest fell into the other division, and Deuteronomy was an independent work. Thus the analysis gave three great elements in the Pentateuch: the Priestly Code; the element remaining when this is subtracted (usually called JE., i.e. Jeh. + Elo.); and Deuteronomy.

Now arose the question of the relative age of these three great divisions. The assumption hitherto prevailing was that the Priestly Code, beginning at Gen. i., and, along with a brief outline of history, containing the bulk of the ritual legislation, was the most ancient element; the other division was more recent, while the age of Deuteronomy, which was assumed to be in the main identical with the Book of the Law discovered in the temple in the eighteenth year of Josiah (621 B.C.), was approximately determined, being at least somewhat anterior to the time of its discovery. At this stage, however, the criticism of the Pentateuch began to take a new movement. The kind of evidence hitherto relied upon had been in the main linguistic, phraseology and style. Now other matters such as history and comparison of laws with one another were drawn into the question.

The criticism of the Pentateuch rose from being a handling of documents to be a new reading and construction of the religious history of Israel. When the three elements were looked at, it was observed that each contained a legislation set in a bed of history. These legislations were the Priestly Code, the Book of the Covenant (Ex. xx.-xxiii.), and Deuteronomy. The questions were asked, 'How do these legislations stand related to one another? and How do they stand in regard to the known historical practice? in other words, How does the national consciousness, as reflected in history, respond to them and testify to their existence?' The answer was that the presumable progress from simplicity to complexity gave the following order: Book of the Covenant (Ex. xx.-xxiii.), Deuteronomy, Priestly Code; and that to this answer history gave its consenting voice, inasmuch as the historical practice for many centuries reflects the Book of the Covenant, which permitted ritual service of Jehovah at different altars (Ex. xx. 24), while Deuteronomy, enjoining sacrifice at one central altar alone, was immediately elevated into a law of the kingdom and regulated practice henceforth; and the Priestly Code, with the hierarchy as rulers of the people, represents the historical situation after the Restoration, when the people, no more a nation but a social-religious community, was governed by the priestly nobles (Neh. viii.). If the further question be asked, 'What was the moving force in this advance from the Book of the Covenant to Deuteronomy and onwards?' The answer is, 'It was the prophetic teaching.' The prophets indeed were as far as possible from having recourse to law themselves. The only law they knew was the Word of the Lord, which was law because it was his word; and their demand was that men should submit themselves to this law freely, because it was good (Micah, vi. 8). They occupy entirely the Christian standing-point. It was in all probability to them a matter of indifference whether Jehovah was worshipped at one or several altars. The whole matter concerned the kind of worship, and the conception of God which it implied. Amos says, in the name of God, 'Seek me and seek not to Bethel'—the god whom the people worshipped was another than Jehovah. And even when Hosea says that the people 'have multiplied altars to sin,' it is not the many altars that he condemns, but the kind of service, which the more it was practised was the greater sin. The insane revelry at the feasts, and the licentiousness that prevailed, was Baal-worship, not service of Jehovah. Others than the prophets, however, perceived that if the ritual was to be purified and one God served, and the evils which the prophets pronounced removed, the rural altars or high places must be abolished; and thus arose the reforms of Hezekiah and ultimately the more complete enforcement of the Deuteronomic law by Josiah.

Such is a sketch of the prevailing view as to the Pentateuch, and the history of ritual in Israel. The strength of the theory lies in its correspondence with the practice, as we observe it in the historical books, and in the general outline of the religious history which it draws. Its weakness lies in the incapacity which as yet it has shown to deal with many important details, and particularly in the assumption, absolutely necessary to its case, that the ancient historical books have been edited from a Deuteronomistic point of view. If the theory be valid, the law as we know it was not the starting-point of Israel's history, but its goal. The prophets did not expound the Law; the Law is a precipitate that formed around the prophetic truths. The prophetic appeals to the people to accept the truths laid before them in the exercise

of their own free will, were in vain; and the truths were embodied in a minute ritual, regulating all the movements of life, and laid as a yoke of bondage on their necks, until the time appointed for their emancipation. The Law reigned from the restoration to the Christian age. Of course, it is an exaggeration of the theory to suppose that the ritual laws were all for the first time written very late; it is reasonable to suppose that they grew up gradually in priestly circles, and were only finally collected and codified at a later period. The great historical work, Judges to Kings, is really one work narrating the fortunes of the people from the settlement in Canaan to the fall of Jerusalem.

The Poetical Books.—Hebrew poetry possesses neither rhyme nor strict measures. Its principle is that of parallelism or sense-rhythm. This balance of two main conceptions gives a corresponding balance to their expression, and makes the lines of Hebrew poetry, though not an exact measure of feet, usually of a similar length. According to the Massoretic view, the Psalms, Job, and Proverbs are the only strictly poetical books in the Bible. The books embraced in the third division, named the Writings, are the expression in the main of two directions of the mind—devotion and religious reflection. To the devotional class belong in general the Psalms; Job, Proverbs, and Ecclesiastes are products of the religious reflecting mind. The Book of Psalms is a collection for purposes of worship of the psalmody of Israel from the earliest times. Our present book is made up of a number of smaller collections, gathered together for the worship in the second temple. Though the collection be late, there is no reason to suppose all or even the greater part of the contents late. It would be as true to say that the Thames rises at London Bridge, as to say that the Psalter dates from post-exile times; but from London Bridge the Thames bears on its bosom the commerce of the world, and from post-exile times the Psalter became the medium for expressing the devotion of the whole community of Israel. How much is implied in this will appear if we call to mind the struggles of the prophets on the one hand, and consider on the other that the Christian church still finds in the Psalter the purest expression of its own praise. The Psalms have many authors, named and anonymous, living at diverse times. It is in general difficult to find certain evidence of authorship for any particular psalm; but there is no reason to doubt that a number, particularly in the first book (Ps. i. xlii.), and some also in the other books, are from the hand of the Singer of Israel, who gives his name to the collection.

The Book of Proverbs also consists of a number of different collections, and is an anthology of the proverbial wisdom of the people. There are no doubt Solomonic proverbs as there are Davidic psalms, though it may be difficult now to determine with certainty which they are. The 'wise man' had definite conceptions of God already formed, and from God he came down upon the world, seeing God reflecting and realising himself in all that happened in events and human life. The universe and human life as part of it was a moral constitution. It was the embodiment of a divine idea, and all its phenomena the expression of this idea. This divine world plan, from being in the mind of God, seemed to take its place outside of God, and be with God. It was the divine wisdom, architect of the universe, for creation and man's life were but this wisdom realising itself externally. This wisdom, the divine idea in all things, let its voice be heard everywhere, in revelation and the orderly life of mankind alike, calling men to hear it and be wise. And the fear of the Lord is the beginning of wisdom (Prov. i. viii.).

This high conception of a divine idea and will realising itself in human life and in history was rudely shattered by the misfortunes of the Exile, and the miseries of the righteous servants of the Lord in later times. The discrepancies between the idea of a righteous rule of God, rewarding all according to their works, and actual providence were too glaring. And many mental conflicts were the consequence. The question is asked in Job, 'Why are the righteous afflicted?' The answer is of various kinds. It is, 'Nay, but, O man, who art thou that repliest against God?' On the side of the pious mind it is this: 'Nevertheless I am continually with thee;' or it is that afflictions are a trial of the righteous. And finally it is the rise of a hope of a final blessedness with God beyond death (chap. xix.), although this hope, as yet too feeble to sustain itself and satisfy, is realised even in this life (Epilogue). Ecclesiastes makes an advance in drawing in the evils of life into life itself, making them a discipline and lesson of humility before God.

Canon of the Old Testament.—So long as the living voice of revelation was heard speaking in the prophets and other public servants of their God, the people would less feel the need of any written canon. The priests were the authorised expounders of the ritual, instructing men orally between clean and unclean (Ezek. xlv. 23), and the prophets and wise men were their moral and political guides (Jer. xviii. 18). Writings that existed were greatly read. Prophets not infrequently quote their predecessors (cf. Is. ii. with Micah, iv.; Amos, i. 2 with Joel, iii. 16; Jer. xlviii. with Is. xv., xvi.); prophecies of the Exile refer to the former prophets (Zech. vii. 12), and the author of Daniel has collected prophecies in his hand (Dan. ix. 2). The only authority which such writings had lay in their claim to contain the word of the Lord; they appealed to men's consciences, and, while pious minds would reverence them, others would neglect them. The heads or rulers of the people had not yet made any of them the public law of the nation. The commencement of the formation of an authoritative canon was made when the Book of the Law, found in the temple (621 B.C.), was elevated into a law of the kingdom by Josiah. The whole Law or Pentateuch was raised into canonical authority when, under the editorship of Ezra and the scribes, all its parts were gathered into one collection, and it was publicly read before the people by Ezra (444 B.C.), and received the sanction of the priests and authoritative rulers of the community. It is probable that the prophetic writings were collected together not much later. The prophetic canon must have been closed before the 2d century B.C., otherwise the Book of Daniel would have been received into it. The third division, that of the so-called Writings, must have been kept open longer; it contains writings of the later Persian or even Greek period (Chronicles, Ecclesiastes); and the Book of Daniel, at least in its present shape, belongs to the first half of the 2d century. There are some Psalms too (e.g. xlv. lxxvii. lxxix. lxxxiii.) which seem to reflect the persecutions of the Syro-Greek period, and Calvin was inclined to refer some of them (e.g. Ps. xlv.) to the Maccabean times. The canonicity of certain books, such as Ecclesiastes and the Song of Solomon, continued to be a subject of dispute in the Jewish schools down to the end of the 1st century of our era. The Council of Jamnia (90 A.D.) finally decided that both these books were to be included in the Writings. It is probable from the lists of Josephus that these books stood in the collection, the point in dispute being whether they had been rightly received into it. It is a curious coincidence that neither of

these books is quoted in the New Testament. The Hebrew canon contained none of the books now known as the Apocrypha. A number of such books, originally written in Hebrew, were translated into Greek, and along with others, such as the Wisdom of Solomon, written in that language, were received into the Septuagint or Greek translation of the Bible. From there they passed into the old Latin version, which was a translation from the Septuagint, and became familiar to the West. When Jerome translated the Old Testament into Latin from the Hebrew (390-405 A.D.), he did not include the apocryphal books in his version. He regarded them as a subordinate class of writings which he called ecclesiastical, useful to be read, but not authoritative. They continued to maintain their place, however, in the Latin Vulgate, the Bible of the West, and were ultimately canonised for the Church of Rome, with certain exceptions, by the Council of Trent. Among the Protestant churches some, such as the Church of England, adhere to the view of Jerome, considering the apocryphal books useful for moral instruction, but not of authority to establish or sustain the faith of the Church; while other churches have entirely rejected them and reverted to the pure Hebrew canon. See APOCRYPHA.

Text of the Old Testament.—The Hebrew text was originally purely consonantal. Of course, words of which the consonants only were written could not be read without supplying vowel-sounds to them; but as yet there were no *signs* for the vowel-sounds. The correct reading of the text was a tradition handed down in the schools. Neither Jerome nor the Talmud (middle of 5th century) knows of any signs for the vowels. The consonantal text was fixed, much as it still remains, before the end of the 2d century; the marks for the vowels and other signs date from the 6th century downwards. Those who occupied themselves with the reading and preservation of the text were called Massorites or Traditionists, and the complete vocalised and punctuated Hebrew text as now printed is named the Massoretic text.

The opinion that at all times the utmost scrupulousness was exercised in regard to the text, and that owing to this care our present Massoretic text may be entirely relied upon, is only partially true. It is true from the time that the consonantal text was fixed—viz. the 2d century of our era; but previous to that time the text of the Old Testament books was subject to all the vicissitudes and dangers to which manuscripts are liable. A comparison—e.g. of Ps. xviii. in the Psalter with the same as found in 2 Sam. xxii.—reveals a multitude of divergences, unimportant no doubt, of the one text from the other. The Massoretic text has to be purified by the same means as are used to gain a pure text of the New Testament. These means are of two kinds, manuscripts and versions. When the existing Hebrew manuscripts, however, are examined, it is found that they are all copies of *one* manuscript, which at some early period, under what circumstances is unknown, had been elevated into a standard, and this standard existing, all manuscripts differing from it gradually fell into desuetude and perished. All existing manuscripts are virtually alike, differing from one another in trivial particulars, chiefly in what is called the plenary or defective writing (i.e. as if in English one manuscript spelled 'honour,' while another read 'honor'); and in the divine names, one manuscript having 'God' where another has 'the Lord.' A comparison of Hebrew manuscripts, therefore, offers almost no contribution to the criticism of the text. Neither are the versions of such use as might have been expected. These versions are the Septuagint, the Syriac, the Targum or Chaldee, and the Latin Vul-

gate; others are late or secondary, being versions from the Greek or Syriac. When the three last-mentioned versions are examined, they are found to be translations of a text virtually identical with our present Massoretic; no doubt all of them, even the Vulgate, the latest, exhibit occasional deviations not without importance; but on the whole they reproduce the Hebrew known to us. And the same is true of the minor Greek versions—now existing only in fragments—of Aquila, Symmachus, and Theodotion.

All these versions belong to the same family with our present Hebrew text. The Targum is valuable as a purely Jewish version. The Syriac must be used with caution, because at some time or other it has been accommodated to the Septuagint. In the great majority of cases where Jerome differs from the current Hebrew he agrees with the Septuagint, by which he may occasionally have been influenced; in a certain number of cases he agrees with the Syriac against the Septuagint, and in some instances his manuscript exhibited readings otherwise unknown. There remains only the Septuagint. This version was gradually produced from the 3d century B.C. downwards. It was executed by different men at different times, and the complexion of the translation varies greatly. It comes, however, several centuries nearer the autographs of the Old Testament writers than we can be sure that the Hebrew does. The Septuagint is of no use except in so far as it can be retranslated back into Hebrew, so as to give us the presumable Hebrew text that lay before the translators. We should then have another Hebrew manuscript to compare with our present Hebrew. The difficulties of reading such a manuscript are enormous. For, first of all, the present text of the Septuagint is in a state of great confusion, and the true Septuagint text is hard to reach. Then, even if it were ascertained, account must be taken of the capacities and procedure of the translator, his faithfulness or otherwise, his ignorance, his arbitrariness, and much else. Then the work of retranslating back into Hebrew requires much skill and experience. And, finally, the Hebrew manuscript being gained, it ranks at best as a manuscript, and its value over against our present Hebrew has to be estimated according to just critical principles. The value of the Septuagint in the textual criticism of the Old Testament is undoubtedly very great, though few scholars have shown perfect aptitude in using it, and, upon the whole, there is a tendency to exaggerate its importance. Besides a number of occasional emendations of the Hebrew which have been based upon it, several more formal attempts to construct the text of entire Old Testament books, mainly after the Septuagint, have been made—e.g. the Proverbs by Lagarde, the Books of Samuel by Wellhausen, and Ezekiel by Cornill. All these attempts are marked by more or less exaggeration of the worth of the Septuagint.

Printed texts of the Old Testament were first issued by the Jews of Italy; the Psalter in 1475; the first complete Bible at Soncino, 1488; Brescia, 1494. The famous printer, Daniel Bomberg of Antwerp, established a press at Venice, whence issued his first edition (1517), edited by Felix Pratensis. Bomberg's second edition (1525-26), edited by Rabbi Jacob-Ben-Chayim, was the first to contain the Massorah, with a text revised after the Massorah. This edition speedily attained a great reputation, and became the basis of most others. The *Complutensian Polyglot* (Alcala, 1517) was prepared at the expense of Cardinal Ximenes. Van der Hooght's edition is well known (Amsterdam and Utrecht, 1705). Editions with various readings from manuscripts are those of Kennicott (Oxford, 1776), De Rossi (Parma, 1784), J. H. Michaelis (Halle, 1720), Norzi (Mantua, 1742). Editions of a number of Old

Testament books corrected according to the Masorah have been issued by S. Baer—Genesis, Isaiah, Minor Prophets, Ezekiel, Job, Psalms, Proverbs, Ezra, Nehemiah, Daniel, and the five Megilloth (Iuthi, Song, Esther, Lamentations, Ecclesiastes), while others are promised.

NEW TESTAMENT.—*Connection of Old and New Testament.*—The Old Testament canon can hardly have been closed before the middle of the 2d century B.C. Many books extant at the time were not included—e.g. Ecclesiastics. The literary activity of the people continued with no intermission. The apocryphal literature may be divided into four classes, not always very distinctly defined: (1) Historical writings, as 1st Book of Maccabees; (2) hortatory narratives—e.g. Judith, Tobit; (3) poetical compositions—e.g. Wisdom of Sirach (Ecclesiastics), Psalter of Solomon; and (4) prophetic writings in imitation of the Book of Daniel—e.g. Book of Enoch, Apocalypse of Baruch, 4th Book of Ezra. These pseudopigraphic prophecies (i.e. bearing the names of others than their real authors) owe their origin to the hard conditions of the life of the people, and on the other hand to an undying faith, rendered more intense by persecution and present afflictions, in the future of the nation. The object which their authors have in view is to confirm the people's steadfastness, and quicken their hope and faith in their ultimate triumph over the heathen. It is only this last class of writings that lie in the line of development towards the New Testament; the others, except some parts of the Psalter of Solomon, follow the line of Pharisaic Judaism. The Christology of Enoch is very developed, though some doubt whether the most Christological part (chap. xxxvii.-lxxi.) has not suffered from Christian interpolation. The term 'Son of Man,' used of the Messiah, may be due to the Book of Daniel (chap. vii. 13) rightly or wrongly interpreted, and the fact that this is not a distinctive Jewish name for the Messiah has little weight, inasmuch as writings of this class emanated more from the popular mind, and were repudiated by learned Judaism. The Psalter of Solomon (middle of 1st century B.C.) expresses the confident expectation of a king of the House of David, who shall lead Israel to the promised glory (Ps. xvii. 1, 5, 23-51; xviii. 6-10, and elsewhere).

There can be no doubt that under the teaching of providence, the Messianic hope, particularly in regard to the person of the Messiah, became, before the Christian era, much more definite and full. This appears abundantly from the New Testament. The dimensions of this hope, however, among the Jews at the beginning of our era may very readily be overstated. It is doubtful, for instance, if there was any idea of a suffering Messiah. Again, it is certain that among Jews outside of Christianity, a great Messianic development took place in the 1st century A.D. This may have been due to Christian influence and intercourse before the final schism between Judaism and Christianity. And thirdly, it is certain that the Christology of the New Testament was largely due to the teaching of Christ and reflection on his life, particularly the conception of the exclusively spiritual nature of his aims and his kingdom. These points exclude that construction of the New Testament literature proposed by Strauss (q.v.). Strauss's two presuppositions were: (1) The supernatural element in the Gospels, being impossible, shows that the narratives arose long after the life of Jesus—they are mythical; (2) the *idees* which have been clothed in history, and have produced the myths, were the popular Messianic ideas of the time. The theory falls with the falsehood of the last assumption. No such developed circle of Messianic ideas can be shown to have existed before Christ.

Another attempt to construct the history of New Testament literature on *a priori* principles, or at least on certain general presuppositions, was made by the Tübingen school. Baur (q.v.) started with the assumption (derived partly from the Epistles to the Corinthians) that the earliest stage of Christianity was characterised by a strong antagonism between Jewish Christianity, represented by the older apostles, which enforced the law on all converts, and a free Christianity represented by Paul. The history of this struggle, the efforts at reconciliation, and the final union in a catholic Christianity, is the history of the Church for two centuries: and the New Testament literature stands like milestones along the road, marking the steps of progress towards catholic union. Baur divided the history into three periods: (1) The period of acute antagonism, represented on the one side by the genuine Pauline epistles (Gal., 1 and 2 Cor., Rom.), and on the other by the Apocalypse (up to 70 A.D.). (2) The middle period, marked by a tendency on both sides to approach one another, the overtures being made first by the Jewish party, who dropped circumcision, and responded to in the later (Pauline) epistles—e.g. Ephesians and Colossians. To this period (70-140 A.D.) belong most of the New Testament literature, the synoptic gospels, Acts, and Hebrews. (3) The period of the consummation of the union (after 140), practically in Rome and the West, and ideally in the Gospel of John, which signalises the victory in thought over the antithesis. The extreme points of Baur's theory have been greatly softened by those who may still in some sense be called his followers.

Rise of a New Testament Literature.—*The Epistles.*—Our Lord left behind him no writing. The tradition of a correspondence with Abgarus, king of Edessa, is fabulous. His gospel was his manifestation on earth, the higher spirit which he breathed into the forms of the old religion, and his life and death. Neither was the gospel propagated by his followers by means of writing; they went everywhere 'preaching' the word. The substance of their preaching was the events of Christ's life and death, his ascension and coming again, with their redemptive meaning—these events with their meaning always supported by the Old Testament Scriptures. When, however, especially through the missionary journeys of Paul, a multitude of believing communities arose scattered over the Roman world, many occasions occurred when apostolic counsel was needed, which could only be given by letter. Hence arose the epistles, which are all of the nature of occasional writings. At the same time advantage was taken of the occasion not only to give advice, but to develop the general principles on which it rested. The epistles of Paul fall in the main between 53 and 63 A.D. Besides other reasons, the Epistles to the Thessalonians were occasioned by a mistaken view of the nearness of the Advent. This idea paralysed human occupations, and agitated men's minds about the state of the dead. The Epistle to the Galatians (55) was written to frustrate an attempt of the Judaizers to impose the law upon this Gentile community. The attempt gave the apostle an opportunity of developing his whole doctrine of grace and justification by faith, the principles of which he had already sketched at Antioch (Gal. ii. 14). The Epistles to the Corinthians owe their origin to the rise of parties in the Church attaching themselves to particular teachers (chap. iii.), to the many practical questions which arose among a community in daily relations with heathen friends outside, and partly also, as was natural on Greek soil, to speculative questions, as about the resurrection (1 Cor. xv.): while the occasion of the Epistle to the Romans was the apostle's projected visit to Italy and the

capital, and to Spain. This epistle has more of the nature of a treatise than any of the others, and is a systematic statement of the apostle's gospel, in view of all the questions which the gospel as he preached it raised, particularly in view of the old economy. Hence as he develops his system he has respect to Judaism at every step. The Jews called all others 'sinners of the Gentiles,' and, when the apostle declares that all alike are concluded under sin, he has to face the question, 'What advantage then hath the Jew?' (chap. iii.) Again, when in the process of his argument he says, 'there is no difference, being freely justified by His grace,' he feels he has to answer the question, 'Whereunto then serveth the law?' (chap. vi.-vii.) And finally the unbelief of the Jew has to be accounted for, which the apostle does by a profound theodicy of the economies, or justification of the ways of God to men; drawing up even this unbelief into the general purpose of God in manifestation of his grace, who 'concluded all in unbelief that he might have mercy upon all' (chap. ix.-xi.).

The type of doctrine in all these epistles is the same. The Christology is a doctrine of atonement by the Son of God, pursued somewhat into the region of Christ's present exalted state. It seems in this state that he is the new man, the head of the new spiritual humanity. The rise of a theosophic heresy at Colosse gave the apostle an opportunity of developing his Christology on another side, the side of Christ's relation before incarnation to the universe and the higher spiritual world, which the Colossians were tempted to worship—'In him all things consist;' 'ye are complete in him, the head of all principality and power.' The Ephesians can scarcely be independent of Colossians; while Philippians, which has most of an epistolary character, belongs to the Roman imprisonment. The pastoral epistles (1 and 2 Tim., Titus) contain, as the name suggests, instructions regarding the offices of the Church, and the character of those who should fill them. These, with the small personal note to Philemon, exhaust the Pauline writings, for Hebrews bears every mark of a different authorship. That epistle was probably written (before 70 A.D.) from Italy (xiii. 24), to some community of Greek Jewish believers, by one himself a Hellenist, who, though he reaches the same conclusion as Paul that the law and the customs have been abolished in Christ, reaches it by a different road, and in a way less liable to wound the susceptibilities of Judaism. Tertullian names Barnabas as the author; Luther suggested Apollos, a view to which many adhere; while others have thought of Luke or Silvanus.

The so-called catholic epistles (1 and 2 Peter, James, Jude) form, along with Hebrews, the contribution which Jewish Christianity made to New Testament epistolary literature. First Peter is addressed to the small Jewish communities of believers scattered throughout Asia Minor, and is designed to sustain them under their sufferings 'as Christians' (iv. 16). James addresses the same class of persons over even a wider area, while Jude has in view some more particular community, whom he warns against a class of persons who do not seem to have been heretics, but libertines not only in practice but in theory, men who turned the grace of God into licentiousness. Second Peter contemplates a similar class of persons, and undoubtedly depends upon Jude. Both James and Jude were brothers of the Lord and not apostles, having become disciples probably only after his death.

Rise of an Historical Literature.—The Gospels.—Acts.—The problem of the origin of the gospels and their relation to one another is very complicated, and many solutions have been offered. (1) It is natural to suppose that by the continuous

intercourse of the disciples with one another, and by conversation on the life and teaching of the Lord, the recollection of one supplementing that of another, as well as by their everyday preaching, the tradition of Christ's life and sayings would gradually assume a certain fixed form with definite outlines. (2) It is equally natural to suppose that in the lapse of years, when changes began to arise, this tradition would be reduced to writing. This supposition is confirmed by the statement of Papias that Matthew wrote down the 'sayings' of the Lord in Hebrew—i.e. in the vernacular Aramean, and every one translated them as he could. The 'sayings' would mainly be the parables and discourses, not chronologically arranged, but grouped together, though probably not without such brief historical hints as to time and locality as were needful to make them intelligible. (3) Considering the increasing relations of the Church at Jerusalem with the outside world, the translation of this collection of sayings into Greek would speedily follow. Such a primitive gospel in Greek, the language in which our gospels are written, is absolutely necessary to explain the coincidences in phraseology with one another which the gospels exhibit. This primitive Greek work lies at the basis of the three synoptic gospels. It has been used by the three with an eclecticism due partly to the idiosyncrasies and partly to the aims of the writers. In each case, however, the 'sayings' have been supplemented from other sources. In the case of Mark, this additional source may have been the personal reminiscences of Peter, according to the ancient tradition of the Church. In the case of Luke, whose gospel professes to repose on formal investigations (i. 3), it is possible that besides the 'sayings' some one of the other two gospels may have been used, while his history of the Nativity, with the accompanying hymns, seems drawn from some written source. It is probable that Matthew preserves the book of sayings with most exactness. The date of Mark is before the fall of Jerusalem (70 A.D.), that of the others perhaps somewhat later. The Gospel of John, dating from near the end of the century, is entirely independent and personal, and possesses more of a subjective character than the others. It is a free reproduction of the life and teaching of Christ, as these had been taken up by a highly ideal and profoundly ethical mind, and combined with its own modes of thought. Hence the sayings and works of Christ are not presented historically and from the outside, but set forth as embodiments and manifestations of certain ideal conceptions, as the 'word,' the 'life,' the 'light,' and others. The gospel contains a good deal omitted by the others, and everywhere bears marks of having been written by an eye-witness. (For the question of the authenticity of this gospel, see JOHN.) The first epistle of John is undoubtedly by the writer of the gospel. The Acts of the Apostles is from the pen of Luke, the author of the third gospel (chap. i. 1). It is probable, from the use of 'we,' that he was an eye-witness of the events narrated in the latter part of the book; for the earlier part of the history he drew on other sources, oral or written. The general purpose of the Acts is to trace the progress of the Kingdom of God from Jerusalem till it overtook the world—from Jerusalem to Antioch; from Antioch to Asia Minor and Eastern Europe; and from there to Rome, the capital, and the world. The book breaks off abruptly with the statement that Paul continued two years in his own hired house, preaching and receiving all that came to him. His subsequent history is left in obscurity. There seems no point in the narrative at which the pastoral epistles can be placed, and hence the hypothesis

of a liberation and 'second imprisonment' of the apostle.

New Testament Prophecy.—The class of 'prophecies' are frequently referred to in the New Testament. There are elements of prophecy in Christ's eschatological discourse (Matt. xxiv.), and also in Paul's Epistles to the Thessalonians, and even in Romans, xi. The only formal book of prophecy is the Revelation of John. It consists of two parts, the epistles to the Seven Churches (chap. i.-iii.), and the Book of Prophecy (chap. iv.-xxii.). The Book of Prophecy (i. 3; xxii. 10) is identical with the book seen on the Father's right hand, the seals of which were opened by the Lamb (chap. v.); this it is which is sent to all the churches. The epistles are accompanying notes to the several churches, containing appropriate exhortations to each in view of the things revealed in the prophecy. Antiquity is nearly unanimous in ascribing the Revelation to the Apostle John. Dionysius of Alexandria, on account of the style, suggested that it might be by another John, the presbyter, mentioned by Papias, a view which has many modern adherents. The style is much more Hebraistic than that of the gospel. It is not, however, the mere language that distinguishes it from the gospel, but the whole type of thought. Like the Hebrew prophecies, the Revelation is external and theurgical, the gospel inward and ethical. In the one the perfect Kingdom of God is introduced, and the destruction of evil accomplished by a direct interposition of God amidst terrible material convulsions; in the other the Kingdom of God is translated into the mind of man, of which it is an ethical condition. If both writings be by the same author, the Revelation must not only be prior, but have preceded the other by a long period of years. The date of composition (if the book be a unity) seems fixed by internal evidence. Chapter xi. must have been written before the fall of Jerusalem; and more precisely the author wrote under the sixth head or emperor (xvii. 10)—i.e. either Galba or Vespasian. When Irenæus says that the Revelation was written under Domitian, he is probably confounding a tradition that the Beast was interpreted of this emperor, with the composition in his reign. (For questions of date and authorship, see REVELATION.)

The Canon of the New Testament.—*The Gospel Canon.*—In point of origin, the epistles preceded the gospels; the canon arose in the inverse order. The preaching of the apostles had strictly no independence of its own; they merely carried the glad tidings regarding Christ to men, and were witnesses of his resurrection. And their writings (the epistles) were merely the supplement of their oral preaching as circumstances arose; the two, in the minds of their converts, stood on the same level. They naturally desired their epistles to be read before all the brethren of the church to which they were sent (1 Thess. v. 27), or sometimes to be exchanged with others sent to a neighbouring church (Col. iv. 16); but these epistles as yet remained the peculiar possession of the church for which they were destined. The canon of New Testament believers was as yet, (1) the Old Testament, which was read in the churches on the Lord's Day, and to which the apostles themselves made continual appeal as the 'Scripture'; and (2) the words or commands of Christ, which are placed on a level with the Old Testament prophets (2 Peter, iii. 2; Rev. i. 2). And this continued to be the mode of thought and expression till the middle of the 2d century, as writers of that time express themselves, 'the Law, the Prophets, and the Lord.' The source from which the Lord's words were known was either oral tradition and testimony, which Papias confesses he prefers to writings, or the written gospels, naturally

chiefly the synoptics, and among these prominently Matthew. All the gospels, however, including John, are already known to the Apostolic Fathers (70-130). The writings of this time are scanty, and their authors had little reason to make direct appeal to the New Testament writings; they betray their acquaintance with them by employing their phraseology, and by allusion, and as there was still a living tradition, their quotations are free. As time wore on, however, and the living memory of the Lord's words died out, the practice arose of reading the gospels along with the Old Testament on the Lord's Day. Justin (died 146) already testifies to this practice, although he himself seems still to distinguish between the gospels as writings, and the Lord's words contained in them. This reading of the gospels naturally led to their being placed on a level with the 'Scripture,' and the formation of a gospel canon. This was really no new step; circumstances and the losses through time merely brought home to the consciousness of the Church what it possessed in the evangelical writings. The four-fold gospel canon is so firmly fixed by the last quarter of the century, that Irenæus is found carrying on an argument to show how there should be just *four* gospels and no more; and in the East, about the same time, there is evidence of a similar collection of the four.

The Epistolar Canon.—The Apostolic Fathers, by allusions and quotations, betray acquaintance with most of the epistles. The allusions to 1 and 2 Thessalonians, Colossians, and Philemon are less distinct, though Ignatius and Polycarp seem to show acquaintance with Thessalonians. The pastoral epistles are well known. No knowledge appears of Jude, 2 Peter, or 2 and 3 John. The epistles, however, are not quoted as authoritative. Clement (96) refers the Corinthians to 1 Corinthians, an epistle directed to themselves; and Ignatius and Polycarp, writing to the Ephesians, refer to their epistle. Clement quotes largely from the Hebrews, and Papias knows the Apocalypse, which Justin ascribes to John. The epistles had been directed to various churches, each of which cherished and used its own; perhaps few, if any, of the churches possessed a complete collection, for no necessity had yet arisen for making such a collection. The Church was in possession of the faith as a living belief; against those without, this belief did not need support, and no contradiction of it of magnitude had yet arisen within. It required the rise of an internal antithesis, a conflict within the Church, to direct her attention formally to the treasure which she possessed in the apostolic writings, and to bring to her own consciousness what all along had been implied in her acceptance of the apostolic preaching and writings, and her faith in them. This needful conflict was found in the rise of dangerous error, especially the Gnostic heresy. This heresy came into collision with the living faith of the Church, and the faith had not only to protest that it was being violated, but to show that it was. This could only be done by showing that the present living faith continued truly to reflect the apostolic preaching; and no means of showing this existed except to show that it continued in harmony with the apostolic writings. This very appeal to the apostolic writings was a canonising of them; and their formal collection and recognition naturally followed. This was again no new step; circumstances merely brought home to the mind of the Church what had always been implied in acceptance of the apostolic preaching and letters. Her latent faith now became formal and conscious; and thus arose a *principle* of canonicity. The Church could not but ask why she had accepted the teaching of the apostles; and the answer was, 'Because they were apostles

commissioned and endowed to teach.' This single principle, however, was difficult to carry through, inasmuch as several of the New Testament writings were not by apostles, as the Acts, Hebrews, and others. And in modern times the Church has felt the same difficulty in finding a single principle to guide it in forming its canon.

Two important witnesses exist for the canon toward the close of the 2d century—the list edited by Muratori (q.v.) for the West, and the Syriac translation of the New Testament for the East. The Muratorian fragment (170 A.D.) counts four Gospels, Acts, thirteen Pauline epistles (excluding Hebrews), 1 John, then Jude; 2 and 3 John are reckoned among catholic epistles. The Apocalypse is included, and it is possible that 1 Peter was referred to in connection with Mark, though the passage is lost. The Syriac translation includes four Gospels, Acts, fourteen Pauline epistles (Hebrews being of the number), 1 John, 1 Peter, James; while Jude, 2 Peter, 2 and 3 John, and Apocalypse are omitted. Both canons fail to include 2 Peter, and the West rejects Hebrews, while the East does not admit the Apocalypse. The writings of Eusebius show that this continued to be the state of matters in the 4th century. He mentions the books which, though known, were disputed—i.e. James, Jude, 2 Peter, 2 and 3 John. He himself does not favour the Apocalypse, but it is to be admitted by those who believe it to be by an apostle. Intercourse between East and West tended to form a canon common to the two; in particular, the scruples of the West as to Hebrews were overcome, as Augustine confesses, by the practice of the East. Finally, the Council of Carthage (397) sanctioned for the West our present collection. It need hardly be said that modern doubts have been extended over a much wider area, including particularly the writings of John, the Acts, and the pastoral epistles.

The Text of the New Testament.—The history of the New Testament text is really a history of the printed editions. The first printed text was that in the *Complutensian Polyglot*, published under the auspices of Cardinal Ximenes. The New Testament was printed in 1514, but not published till 1522. The delay in publication enabled the printer, Froben of Basel, to forestall the issue with an edition hastily prepared by Erasmus from recent manuscripts (1516). Erasmus superintended four editions; the second (1519) was used by Luther in his translation. Frequent editions followed, especially from the press of Stephens at Paris (1546, 1549, 1550), and afterwards at Geneva (1551). In this last edition first appeared our present system of division into verses; that into chapters was already applied in the 15th century to the copies of the Greek New Testament. The text of the Old Testament was early divided into verses by the Rabbins; the division into chapters was first printed in Bomberg's 1525 edition. Beza issued a number of editions, that of 1598 being the basis of the English authorised version of 1611. The brothers Elzevir of Leyden issued their first edition in 1624, and another in 1633. In the preface to the last the words occur: *Textum ergo habes nunc ab omnibus receptum*, which suggested the designation *textus receptus*. These editions had made but scanty use of critical materials. Such materials are mainly of three kinds: (1) Manuscripts, especially the more ancient; (2) ancient translations; and (3) citations in ancient ecclesiastical writers. The principal editions based on these witnesses are those of the following scholars. John Mill (Oxford, 1707) is said to have shown 30,000 variations of reading in the sources used. Wetstein comes next (Amsterdam, 1751). Bengel (Tübingen, 1734) made the important step of attempting to classify the manuscripts into 'families,'

influenced possibly by suggestions made by Bentley. Griesbach (Halle, 1774 *et seq.*; 2d edition, 1796) carried the classification of manuscripts much further than Bengel had done. Lachmann started with the principle of giving, not the original text, but the oldest attainable, that of the 4th century, the age of Jerome (1st ed. 1831; new ed. with testimonies, 1842). Tischendorf gave us a much approved text (1st ed. 1841; 8th ed. 1872); prolegomena by Gregory (1884). Tregelles completed his edition in 1872. The work of Westcott and Hort (London, 1881), the fruit of twenty years' study of the witnesses, their relationships and genealogies, presents the following classification of the materials: (1) A neutral text—i.e. a text still free from the characteristics of the Western and Alexandrian. This text is most perfectly exhibited in the Vatican manuscript (B), less perfectly in the Sinaitic, and is to be held nearest the original form, and probably is the purer Alexandrian text. (2) Western text, early brought to Rome from North-west Syria, and from there widely diffused, especially in the West. This is the prevailing ante-Nicene text. Its characteristics are—a love of paraphrase, a disposition to enrich the text with additions from traditional sources, and a fondness for assimilation and harmonising. It is represented in the Old Latin and Old Syrian versions, and in Fathers over a wide area (exclusive of Alexandria), as Justin, Irenaeus, Hippolytus, Methodius, and Eusebius. (3) A non-Western pre-Syrian text, which may be called Alexandrian. In this text, the neutral text (1), not later than 200, had been subjected to changes which had more to do with language than matter, and are marked by an effort after correctness of phrase. It is represented in Alexandrian Fathers, Origen, Cyril, and in the version of Lower Egypt. (4) Syrian text: the peculiarities of the other texts arose gradually, and, as it were, unconsciously in course of transcription; the Syrian text is strictly a recension or edition made consciously by scholars. It is probably the result of two efforts between 250 and 350 at Antioch to form a lucid inoffensive text. It is 'conflate,' being constructed out of the other texts mentioned above. Critically, therefore, it is without value, as its sources are otherwise known. As Antioch was the mother of Constantinople, this text prevailed at Constantinople from the time of Chrysostom. From there it spread westwards, and from various causes became the predominant text. It lies at the basis of most later versions, of the early printed editions, and of a vast number of manuscripts, particularly of the Cursives.

Versions.—The ancient versions of the Old Testament from the original text are: the Septuagint, Syriac, Targum or Chaldee, and the Latin (Vulgate). Other ancient versions, such as Ethiopic and Arabic, are mainly daughter versions of the Septuagint or Syriac. The ancient versions from the Greek of the New Testament are more numerous:

1. *Syriac.*—(a) The authorised Syriac is the Peshito (simple), supposed to be of the end of the 2d or of the 3d century. This version has undergone revision, and must be used with caution in criticism of the text. The books 2 Peter, 2 and 3 John, Jude, and Revelation were not contained in it. First ed. (Vienna, 1555) by Widmanstadt; later editions—Schaaf (1717), with valuable lexicon; Lee (1823); and a beautiful print in Nestorian type and vocalisation by the American mission at Urmiah. (b) Fragments of the Gospels were edited by Cureton (1858), from MSS. brought from Egypt; and the *Four Gospels* by Bensley, Rendall Harris, and Burkitt from a palimpsest at Sinai in 1894. (c) Philoxenus, Monophysite bishop of Hierapolis, had a literal

version made from the Greek in the interests of his party about 508. This version survives only in a later recension by a monk, Thomas of Heraclea, hence called the Hærclesian (616), edited by J. White (Oxford, 1778-1803). In addition to these a lectionary of the Gospels was published, text, translation, and glossary, by Count Miniscalchi Erizzo (Verona, 1861). The language of this Jerusalem Evangeliary is debased, approaching that of the Jerusalem Talmud.

2. *Latin Versions.*—(a) The old Latin, in the Old Testament, from the Septuagint. It is usually held that this version originated in North Africa, while others contend for Italy. The date is the 2d century. (b) The Vulgate: the text of the old Latin had become so confused in the 4th century that Augustine complained that the recensions were as numerous as the copies. At the solicitation of Pope Damasus, Jerome undertook, when in Rome, a revision of the New Testament. The Gospels were completed about 383, and the whole New Testament soon after. This revision of the old Latin is the present text of the Vulgate. About the same time Jerome revised the Psalter. This 'Roman Psalter' is still used in St Peter's. After going to Palestine (385) he revised the Psalter anew, comparing the Hebrew. This so-called 'Gallican Psalter' is the present Psalter in the Vulgate, and that from which the Prayer-book version was made. Jerome's translation of the Psalter directly from the Hebrew was never received into the Vulgate; it has been recently edited by Lagarde. His translation of the Old Testament from the Hebrew occupied him fifteen years (390-405).

3. *Egyptian Versions.*—(a) The Sahidic, Upper Egyptian, existing only in fragments. (b) The Memphitic, Lower Egyptian or Coptic. Editions: Wilkins (Oxford, 1716); Tattam (1852); Acts and Epistles—Lagarde (1851). Fragments of other versions have been discovered. The date of the Egyptian versions is probably 3d to 4th century.

4. *The Ethiopic* (the Geez, or ancient language of Abyssinia) of the Old Testament is from the Septuagint, that of the New from the Greek. The translation is probably of the 4th century, edited by T. Pell Platt (Camb. 1826-30); the Hexateuch, Billmann.

5. In addition to these may be mentioned the Gothic by Ulfilas (died 383), the Armenian (440), various Arabic versions, and the Slavonic, 9th century.

English Translations.—In modern times versions have appeared in all spoken languages. Partial translations and paraphrases into Anglo-Saxon are still extant. The first complete version in English was that of Wyclif about 1382, from the Vulgate (Forshall and Madden, *Wyclif's Bible*). Of this, however, the gospels alone can be certainly identified as the work of Wyclif himself, and this portion was done as early as 1360. The Old Testament and apocryphal books were translated principally by Nicolas de Hereford. A later complete version of it was finished by Wyclif's friend, John Purvey, about 1388. Printing was introduced into England by Caxton in 1477, and translations and summaries of parts of Scripture appeared in various works from his press. The New Testament of William Tyndale was issued at Worms (1525); later editions (1534-35). Tyndale also translated the Pentateuch, and some other parts of the Bible. The first complete English Bible was that of Miles Coverdale (1535). Coverdale's Bible is based upon the Swiss-German version (Zurich, 1524-29), with the use of Luther, the Vulgate, and Tyndale. Matthew's Bible (1537) is composite: the New Testament is Tyndale's 1535, the Pentateuch is also Tyndale, while of the rest,

part is Coverdale, and part probably from Tyndale's MSS. The so-called Great Bible, a revision of Matthew's, was undertaken under the auspices of Cromwell, Earl of Essex: the printing, being interrupted in Paris, was completed in London (1539). In 1557 the English exiles who had found refuge in Geneva during the reign of Mary, produced a version of the New Testament, with preface by Calvin, and in 1560 the whole Bible. This is known as the Geneva Bible, sometimes popularly as the 'Breeches Bible,' from the rendering, Gen. iii. 7. The version was provided with racy notes, which made it a favourite with the common people (1st Eng. ed. 1576). Meantime a new version had been in preparation under the influence of Archbishop Parker. Separate portions were allotted to different scholars, chiefly of the Episcopal Church, and the whole was then revised by Parker and other learned divines. This version (1568) goes by the name of the Bishops' Bible, vulgarly the 'Treacle Bible,' from the rendering, Jer. viii. 22, 'Is there no tryacle in Giliad?' In 1582 a New Testament was issued by the English Catholic College at Rheims, and the Old Testament in 1609 at Douai. In 1604 James appointed a conference at Hampton Court for determining of things said to be 'amiss in the church.' The suggestion of a new translation, made by Rainolds, was taken up by the king, and six committees were appointed to execute the work. Two of these sat at Westminster, two at Cambridge, and two at Oxford, their work being revised by a general committee. The version appeared in 1611. Finally, the latest revision was due to the suggestion of the convocation of Canterbury. Two companies of translators were appointed, one for the Old Testament, and the other for the New. They began to sit at Westminster in 1870; the New Testament was issued in 1881, the Old in 1885, and the Apocrypha in 1895. After the work had been begun, a number of American scholars were added, and all points of ultimate difference of opinion between the English and American revisers were appended to the versions issued. The monopoly of printing the authorised version of the Bible belongs to the crown, by whom it is granted to certain patentees. See BOOK-TRADE. See H. Stevens, *The Bibles in the Cotton Exhibition, 1450-1877* (1878). The Welsh, Irish, and Gaelic translations will be noted in the articles on the Welsh, Irish, and Gaelic languages.

German and other Translations.—Early in the middle ages translations of portions of the Bible were rendered into many of the western languages, but these were mostly explanatory paraphrases or versions of the Bible narratives in metre rather than translations proper. The Anglo-Saxon paraphrase of Cedmon was a century earlier than Otfrid's *Krist*, a rhymed harmony of the gospels in High German, and the *Heliand* in Low Saxon alliterative verse. The Abbot of St Gall's version of the Psalms (980) and the gospel harmony of 'Tatian,' from the Latin of Victor of Capua, follow next; and to these succeed numerous German versions of the histories and other books. Complete German versions from the Vulgate existed as early as the first half of the 14th century. It is claimed that there were no fewer than seventeen such versions prior to Luther's, and of these five were previous to 1477. Already in the end of the 12th century Provençal translations were in the hands of the Albigenses, and the demand for the Bible in the vulgar tongue spread widely in spite of the prohibition of the Church. In Spain, Alfonso X. of Castile is said to have caused the Old Testament to be translated. Another version was certainly made during the 15th century. The history of the earliest versions in Polish, Italian, and Hungarian is hopelessly obscure. The discovery of printing gave an enormous impetus to the translation and

production of the Scriptures. A Spanish version by Borrell was published at Valencia in 1478; an Italian by the Benedictine Malherbi at Venice in 1471; a French at Paris in 1487; a Bohemian at Prague in 1488; and a Dutch as early as 1477. Luther's translation of the whole Bible was finished in 1534, but the New Testament had been issued as early as 1522. It was by no means, as has been seen, the earliest translation into a German tongue, but it was the first that reached the whole people, and it marked an epoch in the history of High German corresponding to that made in English by the authorised version of 1611. It was quickly translated into Platt-Deutsch, Danish, Swedish, Dutch, and even Icelandic. A revision was commenced in 1863, and not completed till 1882. The Bible of Holland is that authorised by the Synod of Dort in 1637; of Sweden, the official version, prepared by a company of scholars since 1774. The Danish is the work of Resenius (1607), revised by Svaning (1647); the Swiss, an entirely new version prepared in 1772 by Hottinger and others, on the basis of the 1665 version. French versions were made by Lefèvre d'Étaples (Faber Stapulensis) in 1523–28, and Olivetan, a cousin of Calvin's (1535–45). The latter as revised by Calvin in 1551, and later by Beza, became the official text of the French Reformed Church. The translations of Osterwald of 1714 and 1744 are also popular in spite of their conspicuous errors. Another edition still is in use, that prepared in 1588 by the *Vénérable Compagnie* under the direction of Bertram, on the basis of Calvin's, which was subjected to some revision in 1805 and again in 1835. There are many versions of the Old and New Testaments by individual scholars, such as the Latin Testament of Beza, but these belong rather to the history of exegesis. Translations of the Bible have now been made into almost all the languages of the world. See further under the article BIBLE SOCIETY.

The question whether the use of the Scriptures in the vulgar tongue shall be unconditionally permitted to the laity, is one of the main points of opposition between the Roman Catholic and the Protestant Church. In the earliest times, we find no evidence of any prohibition of Bible-reading by the laity. On the contrary, the reading of the Bible formed an essential part of the instruction communicated by pastors to their congregations; and the greatest orators of the Church—especially Chrysostom and Augustine—continually reminded their hearers that private reading and study of the Scriptures should follow attendance on public services. In the middle ages, the distinction, or rather the separation, between the clergy and the laity was gradually widened; but, apart from any question of policy, the widespread ignorance would naturally lead to a dependence on such passages of the Bible as might be read in the public services of the church, even while there was no direct prohibition of its common use. In 1080 Gregory VII. ordained that Latin only should be used in the church services of the West, and thereby indirectly excluded all vernacular readings of Scripture in public worship. Again, with regard to the Waldenses, Innocent III. in 1199 prohibited the private possession and reading of Scripture in the vernacular without the permission of a bishop. Similar prohibitions were repeated at Toulouse (1229), at Béziers (1233), and with regard to Wyclif's translation, which was extensively read, at the synod of Oxford (1383). Indeed, as early as 1234 the synod of Tarragona denounced as a heretic any one who, having a translation of the Bible, refused to surrender it to be burned within the space of eight days. This stringent measure, however, was not generally

adopted. The Council of Trent, being required to pronounce on the question of rival Latin editions of Scripture, declared the Vulgate the only 'authentic' version of the Church. Translations of the Bible—i.e. of the authentic Vulgate, could be possessed only with the leave of the bishops, who were required by Pius IV. to refuse lay persons leave to read these versions unless their confessors or parish priests judged that such reading was likely to prove beneficial. The publication of the New Testament with practical annotations by Paschasius Quesnel (1687) gave occasion to the Roman Catholic Church to speak more definitely on the subject in the bull *Unigenitus Dei Filii* (1713). A later ordinance issued by the ecclesiastical censor in 1757 permitted and even encouraged the use of versions published under papal sanction, and with explanatory notes extracted from the Fathers, such as Martini's Italian version, approved by Pius VI. Within the present century the translations of the Bible Societies have been condemned by Leo XII., Pius VIII., and Pius IX., partly on the ground of their alleged corruptness. The principles, upon which these restrictions of the Roman Church were based, are—that the reading of Scripture is not necessary, that it is unsuitable to the very young and ignorant, and that it is specially dangerous in the hands of evil-disposed persons who have not the key to its interpretation—i.e. the traditional teaching of the Church. But in practice the stringency of the prohibitive discipline has been largely relaxed according to circumstances. For English use, the colleges of Rheims and Douai published an English translation of the Vulgate (New Testament, Rheims, 1582; Old Testament, Douai, 1609), which has gone through a number of editions and revisions (see Cotton's *Rheims and Douay*, 1855). The current editions, provided with the briefest notes to satisfy the rules of the Index of prohibited books (see INDEX), are now practically within the reach of all who care to possess them.

BIBLIOGRAPHY.—Works on the English Bible are: Anderson, *Annals of the Bible*; Eadie, *English Bible*; Westcott, *History of the English Bible*; and Stoughton, *Our English Bible*. Full information on all Biblical subjects will be found in the works on Biblical Antiquities and Archeology by Ewald, Keil, Holzinger, and Nowack; Schenkel's *Bibel-Lexikon* (5 vols.), and Riehm's *Handwörterbuch der Bibl. Altertümer*; the Bible Dictionaries of Smith, Fairbairn, Hastings, and Cheyne and Black. Good commentaries on the whole Bible are Lange's in 24 vols.; the *Kurzgefasstes exegetisches Handbuch* (Old Testament by various scholars, 17 vols.; New Testament, originally by De Wette alone, 3 vols. in 11 sect.); and the Speaker's Commentary in 10 vols. Meyer's Commentary (trans. 20 vols.) and the *Hand-Commentar* (4 vols.) deal with the New Testament alone; Keil and Delitzsch's (27 vols.) with the Old Testament. To the individual books there are countless commentaries both English and German. Books of great value are the 'Variorum Teacher's Bible,' also the Oxford 'Helps to the Study of the Bible,' and the Cambridge 'Companion to the Bible.'

General works on the Old Testament are the Introductions of De Wette (Schrader's edition), Samuel Davidson, Keil, Bleek (revised by Wellhausen), Riehm (1889–90), Driver (1891), Cornill (1892), König (1893); Ewald's *History of the People of Israel*; Milman's *History of the Jews*; Grätz, *Geschichte der Juden*; Kuenen's *Religion of Israel*; Stade, *Geschichte des Volkes Israel*; Renan, *Histoire du Peuple d'Israel*; Schultz, *Alt-testamentliche Theologie* (trans. 1892); Oehler's *Old Testament Theology*; Riehm's *Alt-testamentliche Theologie* (1889), and Smend's *Lehrbuch der Alt-test. Religionsgeschichte* (1893); W. R. Smith, *Prophecy of the Old Testament*; Duhm, *Theologie der Propheten*; Kirkpatrick's *Doctrine of the Prophets* (1892); Ryle, *Canon of the Old Testament* (1892); Buhl, *Canon and Text of Old Testament* (trans. 1892).

Works on the critical question of the Pentateuch: (1) The so-called supplement-hypothesis, Bleek's Introduction. (2) Hupfeld, *Quellen der Genesis* (1853)—the Jeho-

vistic writing not supplementary but independent; thus, there were three elements in the Pentateuch: Priestly Code, J.E., Deuteronomy. (3) On the question of respective age of these elements: Graf, *Die Geschichtlichen Bücher des Alten Testaments* (1836)—the legislation of Priestly Code post-exile; narratives the oldest part of the Pentateuch. (4) Untenableness of this separation shown in essays by Riehm and Kuenen. Graf in an essay (1869) allowed both to be post-exile. Thus the order of elements came to be: J.E., Deuteronomy, Priestly Code. (5) Noeideke, *Untersuchungen zur Kritik des Alten Testaments* (1859)—narratives in Priestly Code not strict history, but merely a clothing of historical ideas. (6) Wellhausen, *Geschichte Israels* (1878), completed Graf's theory. Reuss, *La Bible* (historical books), claims to have taught the theory as early as 1833. Works on the one side are: W. R. Smith, *The Old Testament in the Jewish Church* (1881); Wellhausen, *Prolegomena to the History of Israel* (trans. Edin. 1885); Kuenen, *An Historico-critical Inquiry into the Origin and Composition of the Hexateuch* (trans. Lond. 1886). In defence of the traditional view: W. H. Green (of Princeton), *Moses and the Prophets*, also *The Hebrew Feasts* (New York); E. C. Bissell, *The Pentateuch* (Lond. 1885). Dillmann, in his essay at the end of the last volume (1886) of his complete exposition of the Hexateuch, forming part of the new issue of *Kurzgefasstes Exegetisches Handbuch*, occupies an intermediate position. Delitzsch in his *Neuer Commentar über die Genesis* (1887) puts the Book of the Covenant alone as directly Mosaic—the oldest c. de. The Priestly Code is the most recent—not Mosaic, though its source goes as far back as the Mosaic age. It gradually received successive additions in priestly circles, and was finally rounded off in post-exile times. The narratives in it, however, are ancient and historical. Deuteronomy again is not immediately Mosaic, but a free reproduction of a Mosaic source.

General works on the New Testament: Joseph Angus, *The Bible Handbook*; Bissell, *The Historic Origin of the Bible* (New York); the Introductions of De Wette (6th ed. 1860), F. Bleek (3d ed. 1875), S. Davidson (last ed. 1891), Hilgenfeld (1875), Holtzmann (1887), G. Salmon (1887), B. Weiss (trans. 1887), Godet (trans. 1891 et seq.), and Jülicher (1891); works on the Theology by Schmid, Baur, Weiss, Reuss, Deyschlag, Bruce, Boyon, Adeney; Reuss, *Hist. of Scriptures of New Test.* (trans. 1884); and the following, all trans.: Baur, *Hist. of the first Three Cent.* and *The Apostle Paul*, Hausrath's *New Test. Times*, Schurer, *Hist. of the Jewish People in the Time of Christ*, Weizsäcker's *Apostolic Age* (trans. 1894-5).

The New Testament Canon: Westcott, *Hist. of the Canon*, also *The Bible in the Church*; Charteris, *Canonically*—based on Kirchhofer's *Quellenuntersuchung*; Sanday, *The Gospels in the 2d Cent.*; Reuss, *Hist. of the Canon* (trans. 1884); Zahn, *Gesch. des N. T. Kanons* (1888-92), *Forschungen zur Gesch. des N. T. Kanons* (1881-93); Briggs, *General Introduction to the Study of Holy Scripture* (1899).

The Gospels: Holtzmann, *Die Synopt. Evangelien* (1863); Weizsäcker, *Untersuchungen über die evangelische Geschichte* (1864); Westcott, *Introd. to the Study of the Gospels*; Paul Ewald's *Hauptproblem der Evangelienfrage* (1890); Sanday, *The Authorship and Character of the Fourth Gospel* (1872); Ezra Abbot, *The Authorship of the Fourth Gospel* (Lond. 1880); Luthardt, *St John the Author of the Fourth Gospel* (trans. 1875); and the Introductions to the commentaries by Westcott, Godet, and Reynolds.

Textual Criticism and MSS.: Warfield, *Introd. to the Text. Crit. of the New Test.* (1886); Hammond, *Outlines of New Test. Text. Crit.* (1872); vol. ii. of Westcott and Hort's edition of the *Greek Text* (1885); vol. iii. (1894) of Tischendorf's great *Greek Text*.—the *Prolegomena* by C. R. Gregory; Scrivener, *A Plain Introd. to the Crit. of the New Test.* (2 vols. 1894); Ph. Schaff, *Companion to the Greek Text*, (1887).

Bible Society. an association having exclusively for its object the diffusion of the sacred Scriptures. Perhaps the first association ever formed for the sole and specific purpose of providing copies of the Scriptures for those who were destitute of them, was that founded in 1710 by Baron Hildebrand von Canstein, an intimate friend of Spener, in conjunction with Francke, at Halle, and which, down to 1834, when other Bible Societies had begun to be established in Germany, had distributed 2,754,350 copies of the Bible, and about 2,000,000 copies of the New Testament.—The impulse, however, to the formation of the Bible Societies now existing in all parts of Protestant Christendom proceeded from England, where in 1780 an association was formed for the distribution of Bibles among soldiers and sailors. It was at first simply called *The Bible Society*; it exists to the present day, is now known as the *Naval and Military Bible Society*, and confining itself to its original specific object, has accomplished much good.—In the beginning of 1792, a similar association was formed in London, under the name of the *French Bible Society*, with a similar limited and specific object of distributing Bibles in the French tongue. It was probably the attitude assumed by infidelity in France which gave occasion to the formation of this Society, but the greater part of its funds having been remitted to Paris for printing the Bible there, were lost, and everything belonging to the Society was destroyed in the tumult of the Revolution.

—It was not till 1802 that the first steps were taken towards the formation of the BRITISH AND FOREIGN BIBLE SOCIETY, the parent of a multitude of similar institutions, and the establishment of which must be regarded as the great epoch in the history of this branch of Christian beneficence; nor was the Society fully organised and established till March 7, 1804. Its formation took place in consequence of the deep impression made upon the mind of the Rev. Thomas Charles of Bala, in Wales, by the scarcity of the sacred Scriptures in the sphere of his labours, and particularly by a striking illustration of that scarcity. A little girl who had been saving up her small earnings for some years in order to buy a Bible, after walking 25 miles to procure one, found that they had all been sold. She wept so bitterly that Mr Charles not only contrived to get her a copy, but on his next visit to London, brought the subject of the want of Bibles in Wales under the notice of the committee of the *Religious Tract Society* (q.v.), when it was suggested by Mr Hughes, a member of the committee, that a Society might be formed for the purpose of supplying Bibles not only in Wales, but wherever destitution existed throughout the world. The Society was constituted on the widest possible basis, churchmen and dissenters being alike included in it. It was able to expend only £691 in the first year of its existence, but its annual income gradually increased, and in 1886 amounted to £116,865, from subscriptions, legacies, &c., and £104,889, from sales, &c.—in all £221,754; in 1898 the total was £222,000. Auxiliary and branch societies and dependent associations rapidly sprung up in all parts of Britain and in the colonies, the number of which at present amounts to between 5000 and 6000. Much more than one-half of the expenditure of the British and Foreign Bible Society has been devoted to the diffusion of the authorised English version of the Bible, the only English version with which its fundamental rules permit it to have anything to do; it has also spent large sums in printing and circulating the Scriptures in the different Celtic languages spoken in Great Britain and Ireland, and a very important branch of its operations has been the printing of translations of the Bible prepared by missionaries. The number of transla-

tions of the Scripture—in many cases complete, in others extending only to the New Testament, in some only to particular books—which have been printed or distributed by the Society, is 279 (some being indirectly distributed). Very many are translations never before printed, and many in languages possessing no previous literature. The British and Foreign Bible Society now issues annually above four million copies of the Bible, the New Testament, and such portions of sacred Scripture as have been printed in languages not possessing complete translations. The whole number issued from the formation of the Society to 31st March 1887 was 112,253,547. This Society also employs 26 agents of high education and Christian character, resident in various countries of Europe, Asia, North Africa, and South America, also in Australia and New Zealand. The names of Dr Henderson, Dr Pinkerton, and other agents, must be familiar to many readers. Upwards of 600 colporteurs are employed, chiefly in Europe and Asia. A controversy concerning the circulation of the books of the Apocrypha along with the canonical Scriptures by the British and Foreign Bible Society (see APOCRYPHA), led to a resolution in 1826, that its funds should be devoted, according to its original design, to the diffusion of the canonical books alone.—The EDINBURGH BIBLE SOCIETY became from that time forward an entirely separate Society, till 1861, when the leading Scottish societies amalgamated to form the NATIONAL BIBLE SOCIETY OF SCOTLAND. In 1886 its income was £33,767; its issue for the year, 707,580 Bibles, New Testaments, &c., and total issue nearly ten millions.

The AMERICAN BIBLE SOCIETY is, in the magnitude and importance of its operations, next to the British and Foreign Bible Society. It was founded at New York in 1816, and still has its headquarters in that city, in the 'Bible House,' a very large and magnificent building erected by special subscription. It reckons fully 7000 auxiliary societies in all parts of the United States. Its income amounts to about 524,000 dollars a year, rather more than one-half being derived from sales of Bibles and Testaments, and the rest from donations, collections, &c. The American Bible Society issues annually about 1,500,000 Bibles, New Testaments, and other portions of Scripture, and has in all distributed about 49,000,000 copies. The funds of the Society have been chiefly expended in supplying the wants of the inhabitants of the United States, amongst whom the Indian tribes have not been neglected. 'The Bible Association of Friends in America,' founded at Philadelphia in 1829, has also distributed the Bible extensively.

Of the numerous Bible Societies of Germany, the most important and extensively ramified is the Prussian Central Bible Society (*Hauptbibelgesellschaft*) in Berlin. It was founded in 1814, has branches in all parts of the Prussian dominions, and distributes annually about 80,000 Bibles and New Testaments. There are besides numerous independent Bible societies in other parts of the German empire. A large number of Bibles are still, however, annually supplied to the people of Germany by the agents of the British and Foreign Bible Society. They amounted in 1886 (including Switzerland) to 363,094 copies.—Bible societies were prohibited by the Austrian government in 1817, and some which had already been established in Hungary were dissolved.—The RUSSIAN BIBLE SOCIETY, founded in St Petersburg in 1813, through the exertions of Dr Paterson, and under the patronage of the Emperor Alexander I., entered upon a career of great activity and usefulness, co-operating with the British and Foreign Bible Society for the printing of the Scriptures in the numerous

languages spoken within the Russian dominions; but its operations were suspended in 1826, on the accession of the Emperor Nicholas, its stock of Bibles and the whole concern being transferred to the Holy Synod, under the pretence that the sacred work of supplying the people with the Holy Scriptures belonged to the church, and not to a secular society. The Bibles and Testaments in stock were indeed sold, and very large editions were thus disposed of, but the activity of a society which had no equal in continental Europe was at an end. A Protestant Bible Society was then formed for the purpose of providing editions of the Scriptures, and circulating them among the Protestants of all parts of the empire, which now reckons about 300 auxiliary societies. But the action of this Society 'does not touch the members of the Greek Church, or, if at all, only slightly and incidentally, and it makes no provision of the Scriptures in the language spoken by the great mass of the people. It is merely designed to meet the wants of colonists and others who do not use the Russian language.' Of the translations of the Scriptures published by the original Russian Bible Society, the greater number have never been reprinted since its suppression. The British and Foreign Bible Society still carries on an important work in Russia. The issues in 1886 were 450,115 copies.

Biblia Pauperum ('Bible of the Poor') was a sort of picture-book of the middle ages, giving, on from thirty-four to fifty leaves, the leading events of the Old and New Testaments, each picture being accompanied by an illustrative text or sentence in Latin. A similar and contemporaneous work on a more extended scale, and with the legend or text in rhyme, was called *Speculum Humanae Salvationis*—'the Mirror of Human Salvation.' Before the Reformation, these two books took the place of the Bible with the laity, and were the chief text-books used by the preachers of the mendicant orders. According to one derivation, as these monks took the title of *Pauperes Christi*, 'Christ's Poor,' hence the name; but others explain it as referring to the spiritually poor, the unlearned. Heineken, however, is said to have first employed the title in his *Idee générale d'une Collection d'Estampes* (1771). Many manuscripts of the *Biblia Pauperum*, and of the *Mirror of Salvation*, several as old as the 13th century, are preserved in different languages. The pictures of this series were copied in sculptures, in wall and glass painting, altar-pieces, &c., and thus became of importance in the art of the middle ages. After the invention of printing, each picture and text was at first cut on one block, and the pages were pasted back to back, and made into a book. The use of separate types only increased the popularity of the work; but as improved methods enabled printers to issue the whole Bible, it gradually lost ground, and ceased to be used about the beginning of the 16th century. There have been English fac-simile reprints in 1859, 1877, and 1884 (the last with preface by Dean Stanley).—This book must not be confused with a work of the same title by Bonaventura (q.v.). See BOOK, PRINTING; and for illustration, WOOD-ENGRAVING.

Bibliography, a word which, meaning in Greek merely the copying or transcription of books, was for a long time employed in France for skill in reading ancient manuscripts, and has since the 18th century (as witness De Bure's *Bibliographie Instructive*, 1763) been generally adopted throughout Europe as the technical designation of that department of knowledge which deals with books as books, and takes account of their literary, scientific, or artistic contents only so far as these serve for the orderly arrangement of books or descriptions of

them. The bibliographer distinguishes between a book on art and a book on botany, as the china-merchant or the collector between a tea-cup and a coffee-cup. With the art or the botany as such he has nothing to do. But the material of the book, its size and bulk, pagination, component parts, printing and peculiarities of type, date, authorship, language, place and press of issue (real or pretended), editions (legal or pirated), illustrations, price, abundance or rarity—all these are within his domain. A misprint may be of interest to him, not as affecting the sense of the passage, but as affording (like the mole on a child's cheek) the means of distinguishing two books otherwise apt to be confounded. The ideal accomplishment of the bibliographer's task would be the registration and history of every book (however unimportant in itself) that has ever been published in the world. But though Conrad von Gesner might still compile a *Bibliotheca Universalis* (4 vols. Zurich, 1545-55) without too absurdly misapplying the adjective 'universal,' even he would probably have shrunk from using it had he realised how much he left unchronicled. It is now sometimes the work of a lifetime to trace the vicissitudes of a single book or series of books (for example, the Earl of Crawford on the *De Bry Voyages*), and even then something still remains undone. Many writers have devoted themselves to the classification of books according to some all-embracing scientific scheme; but this inquiry is not strictly bibliographical. The classifier of books must practically adopt those views of the classification of human knowledge most accepted in his own time, and the most perfect scheme will leave on his hands a large residuum of books which refuse to recognise his scientific frontiers.

Of general bibliographies, the most important are Brunet's *Manuel* (6 vols. 8vo, 5th ed. Paris, 1890-95; supplement, 3 vols. 1870-80); Graesse, *Trésor* (7 vols. 4to, Dresden, 1859-69); Ebert, *Allgem. bibliograph. Lexikon* (2 vols. Leip. 1821-30; Eng. trans. by A. Brown, 4 vols. Oxford, 1837); Georgi, *Allgem. Euröpa. Bucherlexikon* (5 parts and 3 supplements, Leip. 1742-58); and Watt, *Bibliotheca Britannica, a General Index to British and Foreign Literature, Authors and Subjects* (4 vols. 4to, Edin. 1824). This last work labours under all the disadvantages of a posthumous publication, but still remains an indispensable *calamum* in every English library.

The tendency to specialise has caused even the more comprehensive schemes to be directed mainly along one of three lines—the registration either of all the works of a single national literature, of those of a single great department of knowledge, or of those marked off by some intrinsic or adventitious peculiarity.

I. NATIONAL BIBLIOGRAPHIES.—For Great Britain, besides Watt's *Bibliotheca*, the standard works of reference are Ames and Herbert, *Typographical Antiquities* (3 vols. 4to, Lond. 1785-90; new ed. by Dibdin, 1810-19, not completed); Lowndes, *Manual* (4 vols. Lond. 1834; new ed. by Bohn, 6 vols. sm. 8vo, Lond. 1857-64); Allibone, *Dict. of British and American Authors* (3 vols. 8vo, Phil. 1859-71; suppl. by J. F. Kirk, 2 vols., 1891); and Sampson Low's *English Catalogue of Books* (4 vols. 1835-90; also a yearly vol. since 1862, and continuing to the present time). These works are arranged according to the names of authors; but the *English Catalogue* is accompanied with *Subject Catalogues*. Sommerschein's *The Best Books* is a valuable guide to the reader (1st ed. with 25,000 works named, 1887; 2d ed. with 50,000, 1891). The *Publishers' Circular* (since 1838), *The Bookseller* (since 1858), *The Bibliographer* (since 1881), and such literary journals as the *Athenæum* and the *Academy*, may be consulted for current

literature. *Notes and Queries*, too, often contains good special bibliographies. In regard to English publications previous to the 18th century, much information is accumulated in Collier's *Rarest Books* (1865); Hazlitt's *Handbook* (1867); and *Collections and Notes* (1876, 1882, 1886); Maitland's *Lambeth Index* (1845); the British Museum *Catalogue of Books printed in England, Scotland, and Ireland up to 1640* (1884); and the *Registers of the Stationers' Company, 1554-1640* (1875-76-77).

For books published in Scotland, reference may be made to Howie, Dalrymple, Dempster, Mackenzie, Nicolson, Irving, Chambers, and Edmond (*Aberdeen Printers, &c.*), though the works are in most cases only partially bibliographical. Books printed in or relating to Ireland are treated of in Shirley's *Catalogue* (1872), and O'Reilly's *Chronol. Account* (Trans. of Berno-Celtic Society, 1820). Of books dealing with the literature of a district, a good example is Courtney and Boase's *Bib. Cornubiensis* (3 vols. 1876-81); of local topographical books, Mayo's *Bibliotheca Dorsetiensis* (1885).

For English books printed in America see the catalogues of Leypoldt (1876), Bowker & Appleton (1876-84), the *Annual American Catalogue*; and the works of Sabin (1869, &c.), Stevens (1856, &c.), Thomas (mainly previous to 1776), and Roorbach. Good bibliographical lists are issued by Mr Winsor, librarian to Harvard University.

The standard French catalogue is that published by Lorenz. It begins with 1840, and has corresponding Subject Catalogues or *Tables des Matières* of great value. Quérard's *La France Littéraire* embraces, with its continuation by Quérard, Louandre, and Bonquet, the 18th and 19th centuries down to 1849 (6 vols. Paris, 1846-57). France has all along been rich in periodicals and serials dealing with bibliography, as *Le Livre*.

Among the authorities for German publications are the series of Frankfort and Leipzig fair catalogues (Messkataloge) (1564-1860) now represented by Hinrichs's *Verzeichnis*; Heinsius, *Bucherlexikon, 1800-1838* (Leip. 1812-89); Kayser, *Volständiges Bucherlexikon, 1750-1890* (Leip. 1833-91), and the *Gesamt-verlags-katalog des deutschen Buchhandels*. Every five years since 1851 Hinrichs has published a catalogue of all the German works of the quinquennium, which have been registered in his half-yearly and quarterly catalogues.

Dutch literature is best represented by Brinkmann's catalogues, for which Van der Meulen has compiled a *Repertorium* (1850-82). As in Germany, the several sections have often elaborate monographs devoted to their bibliography.

Belgium is well equipped with the *Bibliographie Nationale* (since 1830), and the official periodical *Bibliographie de Belgique* (since 1875). See also Schmée's bibliography (1861) of works issued between 1830 and 1860.

The chief names associated with Scandinavian publications are for Denmark, Bartholinus (1666), Nierup (1820), Fabricius (1841-58), Brunn; for Sweden, Lücke (1781-96), and Klemming (1879); for Norway, Nissen (1814-47), Amesen, and Botten-Hansen (1848-65), Boeck (1866-72), Cammermeyer (1867-83), and for Old Norse and Icelandic the *Catalogus Librorum* by Möllus (1856; 1880), and Nierup's *Litteratur-lexicon* (1820). Sweden has an anonymous *Bok Katalog*, and for a time published a monthly *Bibliographi*. The University Library at Christiania issues a *Norsk Bogfortegnelse*.

II. DEPARTMENTAL BIBLIOGRAPHIES.—*Agriculture*.—Weston (1773); André (1847-59); Henning (1860-61); Baldamus (1856-75).

Alchemy.—Barret (1815); Ladragne (1870).

Astronomy.—La Lande (1803); Weidler (1755); Struve, *Pulkova Observ. Cat.*; Holden, *United*

States Naval Observ. Cat.; Houzeau and Lancaster (1880).

Botany.—Pritzel, *Thesaurus* (4to, Leip. 1872-77) and *Iconum Index* (Berlin, 1855-66); Bemmelen, *Repert.* (since 1873); the *Botan. Jahresbericht*; Daydon Jackson, *Index Society* (1882); Trimen, *Bot. Bib. of the British Counties* (1874).

Chemistry.—Zuehold, *Bib. Chemica* (1859, &c.); Ruprecht (1872); Frank, *Führer* (1850-82); Bolton, *Cat. of Chem. Periodicals* (1885).

Classics.—Harwood's *Vier* (1790); Dibdin (1827); Moss, *Manual* (1825); Engelmann (1858); Loscher (1858-69); Mayor, *Guide* (2d ed. 1879; supplement, 1885); and Bursian, *Jahresbericht Class. Alterthumswissenschaft* (since 1873).

Electricity.—Sir Francis Ronald (1880); Salle (1860-83); Hartleben (1883).

Entomology.—Hagen (Leip. 1862-63); Sharswood (Leip. 1858-61); *Wiener entom. Zeitung* (since 1882).

Fine Arts.—*The South Kensington Catalogue and Supplement* (1870-77); Vinet (1874-77).

Geography.—Engelmann (1858); Vivien de Saint-Martin, *Année Géogr.* (1862-82); the Berlin Admiralty *Registrende* (since 1870); Petermann's *Mitteilungen*; *Roy. Geogr. Soc. Lib. Catalogue* (1870); Silver, *Catalogue* (1886); Jackson, *Liste des Bibliogr. Géogr.* (1881); Anderson, *British Topography* (1881); *Diet. de Géogr. à l'usage du Libraire* (1870).

Geology.—Agassiz (1848-54); E. von Berg (1862); *Cat. Museum of Pract. Geology* (Lond. 1878); *Kat. Bibl. der Kön. Geol. Landes Anstalt* (Berlin); *Geological Record* (since 1874); *Bibliogr. of Fossil Insects* (Harvard Un. Bull.).

History.—(1) Medieval and General: Franklin, *Diet. des Noms . . . de Moyen Age* (1875); Chevalier, *Répertoire* (1878); Oettinger, *Hist. Archéol. Karlsruhe* (1841); Adams, *Manual* (1882); Griswold, *Q. P. Indexes, No. IX.* (1882); Koner, *Repertorium* (1852-56); Müldener, *Bibliotheca Hist.* (1870-1882; resumed by Masslow, 1887); *Hist. Zeitschrift* and *Hist. Review.* (2) Great Britain and Ireland: Nicholson (1776); Macray (down to 1600; 1845); Hardy (down to Henry VIII., 1862-71); Gardiner and Mullinger (1881). (3) France: Lelong (1768-78); Ruelle, *Bibl. gén. des Gaulles* (since 1880); Franklin, *Sources . . .* (1877); *Répertoire des Travaux historiques* (since 1882). (4) Germany: Weber (1800); Dahlmann (1875); Kletke (for Prussia; 1858-61). (5) Holland: De Wind (1835); Nijhoff (1871); Fruin, *Repertorium* (1863). (6) Italy: Sir R. C. Hoare's *Catalogue* (1825); Reumont (1863); Lozzi (1886); *Bibliotheca Storica di Deputazione di Storia Patria* (1884); *Archivio Storico* (in progress). (7) Scandinavia: Warnholtz (182-1817) for Sweden; Baden (1815) for Denmark; Horn and Solberg (1884), general. (8) Switzerland: Von Haller (1785-87); Von Sinner (1851); Von Muelinen (1874). (9) India: Elliot (1849), and the *India Office Lib. Cat.* (1888); for China, Möllendorff (1876) and Cordier (since 1878); for Japan, Pagès (1859) and De Rosny (1883); for Persia, Schwab (1875) and Fraehn (1845); for the Jews, Fürst (1849-63); for the East generally, Zenker (1846-61) and Friederici (1875, &c.).

Law.—Mollat, *Verzeichniss, 1820-82* (1886), and Catalogues by H. G. Sweet (1883), and Stevens and Haynes.

Mathematics.—Von Beugheim (1688); Murhard (1797-1805); Rogg (1830); Sohneke (1854); Erlecke (1873); Terquem, *Bulletin* (1855-61); Boncompagni, *Bulletino* (1868-82).

Medicine.—*The Index Catalogue of the Library of the Surgeon-general's Office* (Washington, 1880, and still—1888—in progress) is worth consulting on many matters not strictly medical. It registers not only books and pamphlets but the individual articles of periodicals. Dr Billings, the editor of

this enormous enterprise, founded the *Index Medicus* (1879, &c.). See also Neale's *Medical Digest* (1877; new ed. 1882); Waring, *Bib. Therap.* (1878-79); Clark, *Bibliotheca* (1878); and Schmidt's *Jahrbücher d. ges. Medicin* (since 1834).

Political Economy.—MacCulloch (1845); Mohl (1855-58); Blanqui (1838; 4th ed. 1860); Müllbrecht (1868 and onwards).

Theology.—Of the vast number of guides to the enormous literature classed as 'theological' we can only mention Kempius (1677); Lipenius (1685); Walehius (1757); Le Long, *Bibliotheca Sacra* (various editions); Dorn (1721-23); Döderlein (1780-92); Thiessen (1795-97); Keil (1792); Baldamus (Roman Catholic and Protestant theology apart); Führmann (1813-21); Darling (1854-59); Zuehold (1868); Maleohn (1868); McClintonck and Strong (1867-79); Pettingell (1878); and Hagenbach (1833; 10th ed. Leip. 1880). In 1881 a *Theologischer Jahresbericht* was started by Pünjer.

Zoology.—Agassiz, *Bibliogr. Zoologie* (1848-54); Engelmann, *Bibliotheca Hist. Naturalis, 1700-1846* (Leip. 1846); supplement by Carns and Engelmann, containing articles in periodicals (1846-60); and continuation by Taschenberg; the *Zoological Record* (since 1864); Giebel, *Thesaurus Ornithologie* (1872); Bosgoed, *Bibliotheca Ichthyologica*; the bibliographies in the report of the *Challenger*.

III. SPECIAL AND MONOGRAPHIC BIBLIOGRAPHIES.—*Early Printing*.—The name *Incunabula* or *Incunables* (i.e. 'cradle books') is conventionally applied to all specimens of European typography that issued from the press up to the end of the year 1500. Except that it marks the close of the century which saw the rise of the printer's art, the date has no relation to any bibliographical characteristics: the book of 1501 or 1502 is the same as the book of 1499 or 1498. Didot estimated that 13,000 separate works had appeared in the 15th century, with an average issue of 300 copies, making the wealth of nations in this department amount to about 4,000,000 in 1501; but more recent investigators (Hain, Van der Linde, &c.) have gradually raised the calculation to 30,000 independent publications (including pamphlets) still known to exist, and show that 500 at least may be accepted as the average edition. Works to be consulted in this department are: Sanbertus, *Historia* (Norisbergae, 1643); Panzer, *Annales Typographici . . . ad Annum MD* (continued to 1536; 11 vols. 4to, Norimb. 1793-1803); La Serna Santander, *Diet. bibliogr. choisi du XV^e Siècle* (3 vols. 8vo, Brussels, 1805-7); Laire, *Index Librorum* (2 vols. 8vo, Senonis, 1791); Marchand, *Histoire . . . Imprimerie* (1740 and 1775); Schaub, *Gesch. . . Buchdruckerkunst* (3 vols. 8vo, Mainz, 1830-31); Sotheby, *Principia Typographica* (3 vols. Lond. 1858); Hawkins, *Titles of the First Books*; Legrand, *Bibliogr. hellénique, . . . Ouvrages publiés en Grèce par des Grecs aux XV^e et XVI^e Siècles* (2 vols. 8vo, 1885). Special studies on the incunabula of individual countries and localities are: Claudin (1880) for Albi; Mezger (1840) for Augsburg; Aretin (1801) for Bavaria; Lambinet (1810) for Belgium; Hanky (1853) for Bohemia; Lechi (1854) for Brescia; Baruffaldi (1777) and Antonelli (1830) for Ferrara; Brunet (1865) for France; De Rossi (1795) for Hebrew works; Zapf (1778) and Wurdteim (1787) for Mainz; Saxius (1745) for Milan; Péricand (1840-51) for Lyons; Götze (1872) for Magdeburg; Volta (1786) for Mantua; Panzer (1778) and Roeder (1742) for Nuremberg; Verniglioli (1823) for Perugia; Lelewel (1823-26) for Poland; Canensius (1740) and Laire (1778) for Rome; Frère (1843) for Rouen; Baur (1764) for Spire; Desbarreaux-Bernard (1878) for Toulouse.

Famous Presses.—Some bibliographers confine

themselves to the history of one famous press or publishing house. Thus Butters (1877) chronicles the Bipontine (i.e. Deux Ponts) editions of the classics; Renouard writes the annals of the Aldi (3d ed. 8vo, 1834) and the Stephenses (8vo, 1837-38); Baudini those of the Junta family (2 vols. 8vo, Lucca, 1791); Blades (1861-63) those of Caxton; Duncan (1831) those of the Foulis press.

Individual Authors.—Serviceable monographs have been produced on the works of many important authors and the illustrative literature that gathers round them. For Shakespeare, we have among others, Wilson (1827); Bohn (1863); Mullens (1872-76); Halliwell-Phillips; Winsor. Shepherd has compiled handy bibliographies of Dickens, Thackeray, and Carlyle; and Axon a *Bibliographical Biography of Ruskin*. An elaborate bibliography of Balzac forms one volume of the best edition of his works.

Anonymous and Pseudonymous.—The special difficulty and curious interest of the subject has attracted a large amount of effort to the task of discovering the real authorship of those books which make no sign, or which intentionally mislead or mystify the reader on this point. Besides the old works of Vincent Placcius (Hamburg, 1708) and Mylius (1740), we have for French, Barbier (2d ed. 4 tom. 8vo, Paris, 1822-27), Toinsot (1867), De Maune (1862; 2d ed. 1868), and Quérard (1869, &c.); for German, Ersch (1788, &c.); for Scandinavian, Collin (1869); for Dutch, Van Doorninck (1866); for Belgian, Delecourt (1863); for Italian, Melzi (1848-59); for Russian, Ghennady (1874); for South American, Barros Arana (1882); and for Hebrew, Groddeck (1798). For English, the more serviceable books are Ralph Thomas (pseudonym Olphar Hamst), *Handbook of Fictitious Names* (1868), and *Aggravating Ladies* (1880); Haynes, *Pseudonyms* (1882); Cushing, *Initials and Pseudonyms* (1886); and the *Dict. of the Anon. and Pseud. Literature of Great Britain* (1881, &c.) begun by Mr Halkett, keeper of the Advocates' Library, continued by the Rev. John Laing. Weller's *Moskirt Literature* gives a general view of the subject.

Privately Printed Works have been curiously neglected. J. Martin's *Catalogue* has not been reprinted since 1831.

Periodicals.—This form of literature has become one of the most perplexing problems of the bibliographer: its value is so various, its ramifications so endless. A mere catalogue of the names of periodicals, such as have been long published annually in England, France, Germany, &c., is of little use; and even histories of periodical literature leave the practical question how to find what one wishes barely unsolved. Towards this the 'general indexes' of many of the leading journals (the *Times*, the *Edinburgh Review*, &c.) contribute; and for English and American periodicals the great *Index*, first published by W. F. Poole in 1853 (3d ed. Boston, 1882; suppl. by Poole and W. I. Fletcher to 1st January 1887), is of immense value. A continuation to the last is the *Co-operative Index to Periodicals*, edited by W. I. Fletcher, with the aid of the members of the American Library Association, published quarterly at New York, from 1885 onwards. The Royal Society of London's *Catalogue of Scientific Papers* (1800-63 and 1864-74) includes most scientific periodicals; but as it is arranged by authors' names, stands in need of a subject index. Similar works are Reuss, *Repertorium* (16 vols. Gött. 1801-21); Schnbarth, *Repertorium der techn. Lit.* 1823-53 (Berlin, 1856); and Karl's continuation; and Schotte's *Repertorium der techn. mathem. und naturwiss. Journal-Lit.* (1869, &c.).

General.—Petzholdt's *Bibliotheca Bibliographica* (1864) is an admirable guide to the bibliographies available in his time. It is supplemented rather

than superseded by Léon Vallée's *Bibliogr. des Bibliographies* (Paris, 1883), and its *Supplément* (1887). The British Museum *Hand-list of Bibliographies* (1881), and the bibliographic chapter in Wheatley, *How to form a Library* (Lond. 1886), will also be found useful. See also Bonlard, *Traité élém. de Bibliographie* (1806); Peignot, *Manuel Bibliogr.* (1800), and *Dict. raisonné de Bibliologie* (1802); Namur, *Manuel du Bibliothécaire* (1834); Brunet, *Connaissances nécessaires à un Bibliophile* (Paris, 1878), and *Kat. d. Bibl. d. Borsenvereins d. Deutschen Buchhändler* (Leip. 1886). Sonnensehein's *The Best Books* (1887; new ed. 1891) and *Reader's Guide* (1895), and Fortescue's *Subject Catalogue of Additions to the British Museum* (1886) are of great service to the general reader. Le Petit, *Principaux Editions orig. d'Ecrivains français* (1888), and Könnicke, *Bilder Atlas zur Gesch. der Deutsch. Litt.* (1887), are good examples of art in the service of bibliography. An Index Society was founded in London in December 1877 for the purpose of forming indexes to rare and important books.

Compare articles BIBLIOMANIA, BOOK, BOOK-CLUB, BOOK-TRADE, CHAP-BOOK, HORN-BOOK, LIBRARY, PRINTING; and the lives of Brunet, Caxton, Dibdin, Elzevir, Foulis, Quérard, &c.

Bibliomania (Gr. *ta biblia*, 'the Bible,' and *mantra*, 'divination'), a mode of divination by opening the Bible haphazard, and observing the first passage which occurred, or by entering a place of worship and taking notice of the first words of the Bible heard after entering it. The application was often very fanciful, and depended rather upon the mere sound of the words than upon their proper signification or the scope of the passage. Prayer and fasting were sometimes used as a preparation for a mode of consulting the divine oracles. Bibliomania was prohibited, under pain of excommunication, by the Council of Vannes, 465 A.D., and by the Councils of Agde and Orleans in the succeeding century. It continued, however, to prevail for many centuries thereafter, and is said to have been introduced into England at the Norman Conquest. Tennyson introduces it into *Enoch Arden*. It was essentially the same as the famous *Sortes Virgilianæ*, the only difference being in the book employed.

Bibliomania, the passion of the book-miser, which impels to the gathering and hoarding of books without regard to their literary value or practical utility; or, in its nobler aspect, in Andrew Lang's phrase, the 'love of books for their own sake, for their paper, print, binding, and for their associations, as distinct from the love of literature.' The word in English is modern, having been introduced from France about 1750; but the thing must be in some form as ancient as the existence of printed or written documents. In this, as in other passions of the like kind, the freaks of individual fancy are endless: while one man disdains everything save the 'tallest' copy of a rare work in the finest condition, another takes pity on the dingiest waif of the back-street bookstall. Fashion, too, exercises a great influence on the form in which bibliomania displays itself: it is no longer the prevailing hobby to collect Elzevir and Foulis editions, but he is a special favourite of the gods who possesses a set of the parts of *Pickwick* in the original green paper covers, or of early Thackerays in their original yellow. Competition between collectors leads to the most extravagant prices being paid in the book auction. At the present time Bernard Quaritch, bookseller and bibliophile, has the credit of having paid the largest sum yet recorded as the price of a single volume—£4950 for No. 1650 at the Syston Park sale, December 1884—*Psalmorum Codex*, (folio, Mogunt. Fust and Schöffer, 1459). This quite throws into the shade

the £2260 for the first dated *Decameron* (published at Venice by Valdarfer in 1471), which astonished the buyers at the Roxburghe sale in 1812. At the Syston sale also the so-called Mazarin Bible (one of the twenty-five copies known to have belonged to Cardinal Mazarin), which is the first printed Bible, printed by Gutenberg and Fust about 1450, fetched £3900. In 1827 a copy sold for £504. At the sale of the Earl of Jersey's Oesterley Park library in 1885, the only perfect copy of Malory's *King Arthur*, printed by Caxton, was sold to a Chicago merchant for £1950; Caxton's *Histories of Troye* brought £1820; and Caxton's *Encyclos* brought £2350.

See Dibdin, *Bibliomania* (1811); Hill Burton, *The Book Hunter* (new ed. 1882); Percy Fitzgerald, *The Book Fancier* (1886); Andrew Lang, *Books and Bookmen* (1887); Philomnester, Junior (i.e. Gustave Brunet), *La Bibliomanie en 1883*. See also BIBLIOGRAPHY; and for famous bindings, BOOKBINDING.

Bibra. BARON ERNST VON, a German chemist, explorer, and man of letters, born in Franconia in 1806, and died in Nürnberg, June 5, 1878. His works on chemistry are valuable, and his tales are always marked by fine descriptive power. The result of his travels in Brazil, Peru, and Chili will be found in his *Reisen in Südamerika* (1854), and two later works.

Bicarbonates differ from carbonates in containing twice as much carbonic acid. Bicarburets, bisulphurets, and bitartrates are words formed on the same plan; but in recent chemical nomenclature, the prefix *bi-* has been superseded by *di-*. See CHEMISTRY.

Bice (Ger. *Beis*, Ital. *Biadetto*), the name of two pigments of a blue and green colour respectively, known to artists from the earliest times—blue bice as *mountain blue*, *ongaro*, *azzurro di terra*, &c.; and green bice as *chrysocolla*, *Hungarian green*, *verde de Miniera*, *verde de Spagna*, *verdetto*, &c. These pigments consist of a natural clay mixed with yellow ochre, the blue and green colours being due to native carbonate of copper. Bice has not much body, but dries well with oil. There are several artificial varieties, which, however, are not so durable as the natural. Although a favourite with artists in the beginning of the 19th century, its use is dying out, so that it no longer appears in colour catalogues, its place being taken by 'Hooper's Green.'

Biceps ('double-headed'), an anatomical term applied to two muscles, the one belonging to the arm, the other to the leg, and distinguished from each other as the *biceps flexor cubiti* and the *biceps flexor cruris*. The former is the muscle which gives a full appearance to the front of the upper arm; the latter is situated on the back of the thigh, and is one of a group of three muscles known as the 'hamstrings.' See ARM.

Bicester, a market-town of Oxfordshire, 12 miles NNE. of Oxford, and seat of the county court-house. There are manufactures of rope, clothing, sacking, and pale ale, and several important fairs are annually held. The ruins of *Alia Castra*, or Alcester, lie $\frac{1}{2}$ miles to the south-west, on the ancient Roman Akeman Street. The population is 3343.

Bicêtre, a celebrated hospital, situated on a little eminence in the southern neighbourhood of Paris, and commanding one of the finest views of the city, the Seine, and the environs. Founded by Louis IX. as a Carthusian monastery, it was acquired in 1290 by John, Bishop of Winchester (hence the name Bicêtre), and in 1632 it was destroyed, because it had become a hiding-place of thieves. Afterwards, it was rebuilt by Louis XIII., and made a hospital for old soldiers. It was

for a long time used as a prison for criminals, but is now a hospital for indigent old men and for incurable lunatics.—Bicêtre is also the name of one of the sixteen detached forts that defend the approaches to the walls of Paris.

Bichat, MARIE FRANÇOIS XAVIER, an epoch-making anatomist and physiologist, was born in 1771 at Thoiriette, in the department of Jura. He studied chiefly in Paris under Desault, who adopted him as his son, and whose surgical works he edited. In 1797 he began giving lectures on anatomy, along with experimental physiology and surgery, and in 1800 was appointed physician to the Hôtel-Dieu. Worn out by his unremitting labours, he died of fever in his thirty-first year, July 22, 1802. He was the first to simplify anatomy and physiology by reducing the complex structures of the organs to the simple or elementary Tissues (q.v.) that enter into them in common. This he has done in his *Anatomie Générale* (2 vols. 1801). In his *Recherches Physiologiques sur la Vie et la Mort* (1800), he discusses all the functions of organic and animal life, and their mutual relations.

Bickerstaffe, ISAAC, popular play-writer, was born in Ireland about the year 1735, and at the age of eleven became page to Lord Chesterfield, the lord-lieutenant. He was afterwards an officer of marines, but was dismissed the service for some discreditable offence, and in 1772 had to flee the country on a capital charge. Nothing is certainly known regarding his after-life, but he is supposed to have died on the Continent in or soon after 1812. Of his numerous pieces, produced between 1766 and 1771, the best-known are: *The Maid of the Mill*, *The Padlock*, *He Would if He Could*, *Love in a Village*, *The Hypocrite*, and *The Captive*.—Under the *nom de guerre* of 'Isaac Bickerstaff,' Swift wrote works in 1708-9; and the same name was used by Steele in the *Tatler*.

Bickersteth, EDWARD, evangelical clergyman, was born at Kirkby Lonsdale, Westmoreland, in 1786, and after fifteen years in the General Post-office and in a solicitor's office, was in 1815 admitted to orders, and sent the next year by the Church Missionary Society to reorganise their mission stations in Africa. Having accomplished his mission, he was in 1816 appointed secretary to the Society, a post he filled with great success until 1830, when he became rector of Watton, Hertfordshire. Here, until his death on February 24, 1850, he took an active part in promoting, both by tongue and pen, almost every work having for its object the spread of religious truth whether at home or abroad. He was one of the founders of the Evangelical Alliance. Of his religious writings, which were collected in 16 vols. (1853), the most popular are: *A Help to the Study of the Scriptures*, *The Christian Student*, and *A Treatise on the Lord's Supper*. He also edited *The Christian's Family Library*, a work consisting of 40 vols. His *Christian Psalms* went through 59 editions in seven years. It formed the basis of the well-known *Hymnal Companion*, now in use in more than 2000 churches, prepared by his son, EDWARD HENRY BICKERSTETH (born 1825), who, vicar of Christ Church, Hampstead, from 1855, was in 1885 appointed Bishop of Exeter, and who is author of *Yesterday, To-day, and For Ever*, and other poems.—HENRY BICKERSTETH (1783-1851) in 1836 became Master of the Rolls, and was raised to the peerage as Baron Langdale; and ROBERT BICKERSTETH (1816-84) was Bishop of Ripon from 1857.

Bicycle. See CYCLING.

Bidar, a town in the Nizam's Dominions, near the right bank of the Manjira, a tributary of the Godavary, 75 miles NW. of Hyderabad. Formerly a place of importance, it is now remarkable chiefly

for its manufactures in a compound metal made of tin, copper, lead, and zinc, and called Biddery ware. Pop. 13,000.

Bidassoa, a river which, rising in Spain, forms the boundary between that country and France, and, after a course of 33 miles, falls into the Bay of Biscay at Fuenterrabia. During the Peninsular war its banks were the scene of several conflicts.

Biddeford, a town of Maine, U.S., on the right bank of the Saco River, 6 miles from its mouth in the Atlantic Ocean, opposite the town of Saco (q.v.), and 93 miles NNE. of Boston by rail. It has manufactures of cotton and woollen goods and machinery, and there is a large trade in timber. It was settled about 1630, and named by settlers from Bideford in England. Pop. (1890) 14,443.

Bidding-prayer, a form of exhortation, always concluding with the Lord's Prayer, enjoined by the 55th canon of the Anglican Church, in 1603, to be used before all sermons and homilies. Except in cathedrals and the university churches, it is now seldom used. The term is from the Anglo-Saxon *biddan*, 'to pray,' so that 'bidding-prayer' is really pleonastic. The form is of extreme antiquity, and we have a similar one in the Apostolical Constitutions. It was anciently used for the communicants or believers after the dismissal of the catechumens, and was pronounced by the deacon, each petition beginning with the words, 'Let us pray for,' &c., and the people responding at the end of each with 'Kyrie Eleison,' or some such words. There is another very ancient example in the Ambrosian Liturgy; and St Chrysostom alludes to such a form in one of his sermons. It must have been, and even now in its abridged shape still is, very impressive, allowing each individual to supply from his own thoughts special cases of necessity under the different heads. These Bidding-prayers have some resemblance to the Litany and the Prayer for the Church Militant, now used in the Anglican Church.

Biddle, JOHN, sometimes called the founder of English Unitarianism, was born in 1615, at Wotton-under-Edge, in Gloucestershire, and in 1634 entered Magdalen Hall, Oxford, where he took his degree of M.A. In 1641 he was elected master of the free school in the town of Gloucester; but having embraced certain opinions in regard to the personality of the Holy Spirit, at variance with those held by the majority of Christians, he was thrown into gaol, December 1645. He was summoned before the parliament at Westminster, tried, and thrown into prison. The famous Westminster Assembly of Divines undertook to 'settle' Biddle's case, but their arguments had only the effect of strengthening his previous convictions. His work on the Holy Spirit, issued in 1647, was burnt by the hangman as blasphemous. In 1648 he published a *Confession of Faith concerning the Holy Trinity*, which was followed by another tract containing the opinions of the Fathers on the same question. Parliament had passed an act declaring the denial of the Trinity a crime punishable by death, and the Westminster Assembly besought parliament to have Biddle executed. Parliament did not respond to this appeal, he never was brought to trial, and personal friends secured his liberation by becoming surety for his appearance when wanted. Cromwell's Act of Oblivion gave him full liberty. He now commenced to gather a congregation of those whom he had converted to his opinions. Twice during the Commonwealth Biddle suffered severely for his creed, and in 1655 was banished to one of the Scilly Isles. In 1658 he was released, and continued to preach in London till the death of Cromwell, and also after the Restoration, until June 1662, when he was again apprehended and fined in £100.

He could not pay it, so was committed to gaol, where he died 22d September of the same year. See UNITARIANS.

Biddle, NICHOLAS, an American financier, born at Philadelphia, January 8, 1786, graduated at Princeton College, and became an energetic member of the legislature of Pennsylvania. In 1823 he was appointed president of the United States Bank, and held that post till 1836. He was next chosen president of the United States Bank of Pennsylvania, but resigned in 1839; two years later the bank became insolvent. He had conducted its affairs with great skill, integrity, and prudence, and he published a series of letters in vindication of his administration. A presentment was made against him for fraud, which was never followed up. Biddle had considerable literary taste, and for some time edited *The Philadelphia Portfolio*, contributing many articles to its pages. By request of the president of the United States, he compiled from the original papers a *History of Lewis and Clarke's Expedition to the Pacific Ocean*; also *The Commercial Digest*, a volume put forth by Congress. He died February 27, 1844.

Bideford, a 'little white seaport town' of North Devon, on both sides of the Torridge, 3½ miles above its confluence with the estuary of the Taw, and 9 miles SW. of Barnstaple. The name signifies 'by-the-ford,' and is pronounced *Bid-de-ford*, like that of its American daughter. The old bridge of 24 arches and 226 yards long, which unites the two divisions of Bideford, was widened in 1864. The church was rebuilt, all but the tower, in 1864. There are manufactures of ropes, sails, earthenware, and leather; and these are exported, together with oak-bark, corn, flour, linens, woollens, iron, &c. Vessels of 500 tons can get up to the quay. Pop. (1891) 7831. A place of Viking sepulture, Bideford was the port whence Sir Richard Grenville sailed on his last voyage, and it figures much in Kingsley's *Westward Ho!*

Bidpai, also PILPAY, the reputed author of a collection of fables and stories widely circulated both in the East and West, of which the earliest extant form exists in an Arabic version of about 750 A.D. The original was an Indian collection of tales which are not now in existence, but of which the *Panchatantra* (q.v.), and to a lesser degree the *Mahābhārata* (q.v.) and the *Hitopadesa* (q.v.), contain each a part, though in a modernised and artificially elaborated form. Of this Indian original, the classical and elegant Arabic version, *Kalilah wa Dimnah*, already spoken of, is a substantially faithful reproduction. It was not made, however, direct from the Sanskrit, but from a lost Pehlvi version, the parent also of an incomplete old Syriac version, dating from about 570, which was discovered in the episcopal library at Mardin at the time of the Vatican Council, and published in 1876 by Bickell with an introduction by Benfey. Save this, every known version of the book descended directly or indirectly from the Arabic version of Abdullah-ibn-Almokaffa of 750. This work as it exists is made up of three elements: Indian, Persian, and Arabic, three chapters being Persian, and six appearing first in the Arabic version, while twelve chapters are of Indian and Buddhist origin. Of these last, five correspond to the five chapters composing the *Panchatantra*, two appear in the first book thereof, three are found in the *Mahābhārata*, and two seem to have fallen out of the Indian literature altogether. However, if Buddhism originated the book, it was Islam which transmitted it to Europe, for no fewer than five different translations were made from the Arabic version—into Syriac (10th or 11th century); Greek (about 1080 by Symeon Seth); Persian (about 1120,

a somewhat free translation, known as that of Nasrullah); Hebrew (13th century by Jacob ben Eleazar); and Old Spanish (1251, from which Raimund's Latin version was made in 1313). A somewhat earlier Hebrew version formed the basis of the *Directorium* (about 1270) of John of Capua, a converted Jew; which in turn gave rise to German by Graf Eberhard (about 1480); Spanish, the *Exemplario* (1493); Italian, (Doni's *Moral Filosofia* (1552), and Firenzuola's *Discorsi degli Animali* (1548); French; English (1570); Danish (1618); and Dutch (1623) versions. The English edition was a rendering by Sir Thomas North (1570) of the Italian *Moral Filosofia* of Doni. The Persian of Nasrullah gave birth to the *Anwari-Suhaili*, or 'Nights of Canopis the Star' (late in 15th century), of Husain Wā'iz, which in turn gave rise to the Turkish *Humâyûn Nâmâh*, or 'Imperial Book' (early in 16th century).

As to the original transmission of the book from India, the story is told that the Persian king Khosrû Nûshirvân (531-79), hearing of its existence in India, despatched his physician Barzöye to India to procure and translate a copy of it into Pehlevi, the literary dialect of Persia. Its translator into the older Syriac version was an ecclesiastic named Bâd (or Bôd); into Arabic, the elegant and accomplished but ill-fated scholar, 'Abdullah Ibn al-Mokaffâ'. Of this work each chapter forms a story which is supposed to have been related to a king of India by his philosopher, Baidaba or Bidpai, to point some moral. The story itself is simple in form, but usually branches out into a number of parenthetical stories, conversations, and sayings. In many of the stories animals play parts, and act as if men and women. With the chapter on the lion and the ox, or how two friends may be set at variance by a crafty interloper—the fifth in De Sacy's text—we enter on the original Indian book. The name given to the book, in Arabic *Kalilah* and *Dinnah*, in Syriac *Kalilag* and *Dammag*, is derived from the Indian names of the two jackals who take a principal part in this story. Perhaps the most pleasing story in the book is that of the ringdove, or the love of sincere friends. The 14th chapter in De Sacy, the story of the king and his dreams, is unmistakably Buddhist, the Brahmins in it being presented in the most odious light. In this story none of the parts are taken by animals. The account of the mission of Barzöye to India, and his biography, are given in all the versions except the later Syriac just before the story of the lion and the ox, and after the table of contents. The prominent part which asceticism plays in this biography Benfey connects with Buddhism, then in full vigour in India.

An eclectic text of the Arabic version was edited by Silvestre de Sacy (Paris, 1816), and has been translated into English by Knatchbull (Oxford, 1819), and into German by Phillip Wolff (2 vols. Stutt. 1839). The later Syriac version was edited by Professor Wright (1884), and was translated into English, with an excellent introduction, by the late I. G. N. Keith-Falconer (1885).—See also Loiseleur Deslongchamps, *Essai sur les Fables Indiennes* (Paris, 1838); Max Müller, 'On the Migration of Fables,' in vol. iii. (1880) of *Chips from a German Workshop*; and Rhys Davids, *Buddhist Birth Stories* (1880).

Biebrich, a town on the right bank of the Rhine, 2½ miles S. of Wiesbaden; pop. 11,023. It has the castle of the Dukes of Nassau, and manufactures cement, manures, sulphuric acid, and stucco.

Biel. See BIENNE.

Bielefeld, a busy town in the Prussian province of Westphalia, picturesquely situated on the little Lutter, at the foot of the Teutoburger-Wald,

28 miles SW. of Minden. The old walls which withstood the last siege in 1673, have been converted into promenades. Bielefeld is the centre of the Westphalian linen-trade, its yearly output having a value of about £50,000. It has extensive bleaching-grounds, manufactures of woollen thread, soap, leather, and its meerschaum pipes are celebrated. Pop. (1871) 24,521; (1890) 39,350.

Bieleff, an ancient town of Russia, in the government of Tula, on the Oka, 160 miles SSW. of Moscow. Pop. 9171.

Bielitz, a town of Austrian Silesia, on the left bank of the Biala, 60 miles SW. of Cracow by rail. It has dye-works, and carries on a trade in woollen cloths, wine, and salt. Pop. 14,573.

Biella, a town of North Italy, in the province of Novara, 56 miles NE. of Turin by rail. It has some manufactures, and is the seat of a bishop. Pop. 11,662.

Biëlo-oz'ero ('White Lake'), a lake in the government of Novgorod, Russia, covering an area of 432 sq. m., its length being about 25 miles, and its breadth 20. Its surplus waters are conveyed by the Sheksna River into the Volga, and canals unite it with the Onega, Sukona, and Dwina.—**BIËLO-ZERSK** is an old wooden town on the south shore of the lake. Pop. 4286.

Bielopol, a town of Russia, 106 miles NW. of the city of Kharkov, with extensive brandy distilleries. Pop. 12,178.

Bielshöhle, a stalactite cavern in the Harz Mountains, on the right bank of the Bode. It was discovered about 1672, but first made accessible in 1788. Its entrance is 108 feet above the bed of the stream; and its total length is 230 yards.

Bielsk, a town of Russia, in the government of Grodno, 112 miles NE. of Warsaw. Pop. 9763.

Bienne, in German **BIEL**, a town of Switzerland, in the canton of Bern, 56 miles SW. of Basel by rail, beautifully situated at the base of the vine-clad Jura, and at the foot of the Lake of Biemme. Pop. (1890) 16,937, engaged in the manufacture of watches, leather, cotton, &c. Biemme is mentioned as early as 814. From 1262 it belonged to the bishops of Basel; but in 1352 it entered into an alliance with Bern, and after the Reformation was essentially a free and independent city until 1798, when it was annexed to France. In 1815 it was united to Bern.—The **LAKE OF BIENNE**, lying 1424 feet above sea-level, extends 9 miles north-eastward along the base of the Jura Mountains, its greatest breadth being 3 miles. It receives the surplus waters of Lake Neuchâtel by the Thiel, by which river it again discharges its own. Its maximum depth is 256 feet. Towards its head is the Ile St Pierre, to which Rousseau retired for two months in 1765.

Biennials, or **BIENNIAL PLANTS**, are plants which do not flower in the first season of their growth, but flower and bear fruit in the second season, and then die. The most familiar example is perhaps that of the common foxglove (*Digitalis*). Many of our cultivated plants are biennials, as the carrot, turnip, parsnip, parsley, celery, &c., and many of the most esteemed flowers of our gardens, as stock, wallflower, honesty, &c. But plants which in ordinary circumstances are biennials, often become Annuals (q.v.), when early sowing, warm weather, or other causes promote the earlier development of a flowering stem, as is continually exemplified in all the kinds already named. If, on the other hand, the flowering of the plant is prevented—or, in many cases, if it is merely prevented from ripening its seed—it will continue to live for a much longer period; the same bed of parsley, if regularly cut over, will remain productive

for a number of years, while a normally annual plant like *mignonette* may be kept growing for two years or more if its flowering be carefully prevented.

Bierstadt, ALBERT, an American artist, born at Düsseldorf in 1830, was brought next year to the United States, but studied in Europe, 1853-57. In 1859 he visited the Rocky Mountains, and the first result of his sketches was 'Lander's Peak' (1863), which created some impression at the Paris Exposition. Since then, mountain scenes have been his favourite subjects, and these he treats with considerable vigour of drawing and brilliancy of colouring. He has received decorations from several continental countries, and is a member of the St Petersburg Academy.

Bies-Bosch, a marshy sheet of water of the Netherlands, extending over an area of 77 sq. m., between the provinces North Brabant and South Holland.

Biestings. See BEESTINGS.

Biffin. See APPLE.

Bigamy, according to the canonists, consisted in marrying two virgins successively, one after the death of the other, or in once marrying a widow; and persons so offending were held to be afterwards disqualified for holy orders. But according to the ordinary English use of the word since the 13th century, bigamy is the entering into a second marriage while the first subsists; and this is condemned by the civil law and the church law of all modern civilised states. The severe English statute of 1604 was modified in 1829, punishment of penal servitude (for not more than seven years) and imprisonment being substituted for that of death. The Scottish statute of 1551 was directed against the perjury involved in the violation of the solemn marriage oath taken in church; but even in cases of the most irregular marriage by the mere exchange of consent, bigamy is recognised by the common law of Scotland as an offence, and in spite of the protests of Baron Hume, has frequently been punished by imprisonment, and penal servitude is, in the discretion of the judge, also sometimes inflicted. An account of some foreign laws will be found in the Report of the Royal Commission on the Marriage Laws, 1868.

The English Act of 1829 excepts from its provisions the following four cases: (1) That of a second marriage contracted out of England by one who is not a subject of the realm. (2) That of any person marrying a second time, whose husband or wife shall have been continually absent from such person for the space of seven years, and shall not have been known by such person to be living within that time. (3) That of a person who, at the time of such second marriage, shall have been delivered from the bond of the first marriage on grounds recognised by English law. (4) That of a person whose former marriage shall have been declared void from the beginning by any court of competent jurisdiction. These exceptions bring out some points of difference between the English and Scottish laws. (1) The Scottish law would treat the foreign marriage as an offence against the law protecting the first marriage at home, and would therefore punish in this case also. (2) Reasonable ground for believing in the death of the first spouse would be a defence to a prosecution for bigamy in Scotland, although seven years had not elapsed. (3) The English law does not recognise divorce from the first marriage as a defence, unless it has been given in such circumstances as justify divorce on the comparatively limited grounds recognised by the English Divorce Act. Hence, in the famous case of *Lolley*, an Englishman was convicted of bigamy in England, although he had obtained in Scotland a

divorce from the first marriage on the ground of adultery. There is a tendency in the English courts now to treat divorce as an incident of the law of the domicile of the spouses, but the matter remains in an unsatisfactory position. (4) It will be understood that bigamy is committed whatever may be the legal impediment otherwise (e.g. relationship) to the attempted second marriage. The unmarried person who knowingly enters into a bigamous marriage is treated as a principal in the second degree in England, and as art and part in Scotland.

In the United States, bigamy is everywhere treated as a crime, punishable by fine and imprisonment. It is punished in the several states by state laws giving the courts discretionary power to fix the punishment. The law gives the minimum and maximum punishment, usually from one to three years' imprisonment and \$500 and \$1000 fine.

Bigelow, the name of several notable Americans, of whom the most important are—(1) ERASTUS BIGGAM, born in Massachusetts, 1814; invented, while yet a lad, looms for weaving suspender webbing and piping cord, and afterwards constructed a machine for making knotted counterpanes, and a valuable loom for weaving carpets. He died in 1879.—(2) JACOB, physician, born in Massachusetts, 1787; graduated at Harvard University in 1806, and early became known as a skilful botanist. He practised for over forty years in Boston, and filled several chairs at Harvard. His professional publications are numerous, and the single-word nomenclature of the *American Pharmacopœia* of 1820, afterwards adopted in England, is largely due to him. He died 10th January 1879.—(3) JOHN, born at Malden, New York, 1817, was managing editor of the *New York Evening Post* from 1850 to 1861, when he went as consul to Paris. From 1865 to 1866 he was United States Minister in France; and in 1875 he was elected secretary of state of New York, but since 1877 he has taken no part in politics. He has, among other works, written *Lives of Fremont* (1856) and *William Cullen Bryant* (1886), besides editing Franklin's *Autobiography* from the original MSS. which he found in France (1868; new ed. 3 vols. 1875); Franklin's *Complete Works* (1886), and Tilden's *Writings and Speeches* (2 vols. 1886).

Bigg, or BIG BARLEY, a local name for the common bere, or four-rowed barley (*Hordeum vulgare*). See BARLEY.

Biggar, a town of Lanarkshire, 28 miles SW. of Edinburgh, with which it has connection by rail. The Collegiate Church of St Mary was founded in 1545; of Boghall Castle, the seat of the great Fleming family, hardly a vestige remains. Dr John Brown, author of *Rob and his Friends*, was born in the United Presbyterian manse; and John Gladstones (1693-1756), great-grandfather of W. E. Gladstone, is buried in the churchyard. Pop. 1356. See Hunter's *Biggar and the House of Fleming* (2d ed. 1867).

Biggleswade, a market-town of Bedfordshire, 41 miles NW. of London by rail, with a great corn-market. Pop. of parish, 4943.

Bighorn. See SHEEP, Vol. IX. p. 377.

Big Horn, a navigable river of the United States, and the largest affluent of the Yellowstone, rises near Fremont's Peak in the Rocky Mountains, in the NW. of Wyoming territory. It has a north-east course of about 350 miles.

Bignoniaceæ, a tropical order of corollifloral dicotyledons, closely allied to the Scrophulariaceæ (q.v.), from which they may be distinguished by the longitudinal dehiscence of the capsule, and by their winged exaluminous seeds (see TRUMPET-

FLOWER). They are in many cases noble trees, and some of them afford valuable timber, among which may be named *Bignonia leucocylon*, a tree of Jamaica, which is sometimes imported for cabinetmakers, &c. under the name of green or

Bignonia radicans.

yellow ebony; some Brazilian species (*Jacaranda brasiliensis*) furnish exceedingly hard and beautiful timber. Not a few of them are climbing shrubs (lianas), and the tough shoots of *Bignonia kerere* are used for wicker-work in Guiana. *Bignonia alliacea*, a native of the West Indies, is remarkable for its strong alliaceous smell; the leaves of *Bignonia Chica* afford the red colouring matter called Chica (q.v.).—Some are herbaceous; of these the most important is *Sesamum* (q.v.).

Bigod, the name of a family founded by a poor Norman knight, which acquired the earldom of Norfolk in the reign of Stephen. The second earl, Roger, took a prominent part in securing Magna Charta; in 1306 the earldom became extinct.

Bigorre, a mountainous district of South-west France, formerly belonging to Gascony, but now for the most part embraced in the department of Hautes-Pyrénées. Tarbes (q.v.) has been the chief town since the days of the Romans. See BAGNÈRES.

Big Sandy River, also called *Chatterawah*, a navigable affluent of the Ohio, formed by the junction of two branches which rise in Virginia. The west fork traverses several counties of Kentucky, and the east fork is, during the later part of its course, the boundary between the two states.

Bihacz (*Bihatch*), a strong fortress-town of North-west Bosnia, on the Una, near the Croatian frontier. It has been the scene of frequent contests during the Turkish wars, and there is a fine monument to the Austrians who fell in the campaign of 1878. Pop. 3597, mostly Mohammedans.

Bihé, a fruitful district of South Africa, E. of Benguela, and under Portuguese influence. The eastern part rises to a lofty plateau, where the climate is delightful. Bihé is an important caravan centre, as the only route across the continent south of the Congo passes through it. The trade is chiefly in slaves and ivory. Area, 2500 sq. m.; pop. 95,000. Kagnomba, the king's capital, is more than 3 miles in circumference. See Major S. Pinto's *How I Crossed Africa* (1881).

Bijanaghur. See VIJAYANAGAR.

Bijapur, a decayed city in the Bombay Presidency, 160 miles SE. of Poona. It was for centuries the flourishing capital of a powerful kingdom, but fell therewith under various dynasties in succession, Hindu and Mussulman, till in 1686 it was captured by Aurungzebe. It passed during the

early part of the 18th century into the hands of the Mahrattas, and became British in 1848. Now that a gradual decay has done its worst, Bijapur presents a contrast perhaps unequalled in the world. Lofty walls of hewn stone, still entire, inclose the silent and desolate fragments of a once vast and populous city. With the exception of an ancient temple, the sole relic of aboriginal domination, the ruins are Mohammedan, and consist of beautiful mosques, colossal tombs, a fort, with an inner citadel, a mile in circuit. The British government has done everything to prevent further decay. Pop. 16,759. See Fergusson's *Indian Architecture* (1876).

Bijawar, a petty native state in the Bundelkhand Agency, with an area of 974 sq. m. Diamonds and ironstone are found, but the country is poor and hilly. Pop. 123,414.

Bijbharu', or BIJBAHAR, a town in Kashmir state, India, on the Jhelum, 25 miles SE. of Srinagar. It is the second city in the state.

Bijnaur, a town of the North-west Provinces, 3 miles E. of the Ganges. Sugar, Brahmanical threads, and cotton cloth are manufactured. It is a seat of the American Methodist Mission and headquarters of the Jâts. Pop. 15,147.—The district of Bijnaur, in the N. of the Rohilkhand division, contains more than a dozen towns with a population of over 5000. It has an area of 1868 sq. m., and a pop. of 794,870.

Bikaner, the capital of a Rajput state, lies in a desolate tract, 250 miles WSW. of Delhi. It is surrounded by a battlemented wall of 3½ miles in circuit, and from a distance presents a magnificent appearance; but many of the carved buildings for which it is notable are situated in narrow and dirty lanes, and the people are extremely dirty. There are seven Jain monasteries. Pottery, stone-cutting, and carving, the making of a white candy and of blankets, are amongst the industries of the place. Pop. (1891) 56,262.—The state contains 23,090 sq. m., and a pop. of 831,955. The Rajputs are the dominant race; but Jâts form the great body of the inhabitants. The greater part of the state is a dreary, undulating plain interspersed with shifting sandhills, grass, and jungle bushes. The horses, cattle, and buffaloes of Bikaner are famous. The climate is remarkable for extreme changes of temperature.

Bikh is an Indian poison. See ACONITE.

Bilba'o, a town of Northern Spain, the capital of the Basque province of Vizcaya (Biscay), is situated in a mountain gorge on the Nervion, 8 miles SE. of its mouth at Portugalete, and 63 miles N. by E. of Miranda by rail. Bilbao is well built; the principal streets are straight and the houses substantial; but there are no public buildings of any note. Four bridges span the river, which divides the old town from the new. The city is purely commercial. There are docks for building merchant-vessels, and in the vicinity are iron and copper mines. The old fame of Bilbao's iron and steel manufactures is attested by the terms *bilbo*, 'a rapier,' and *bilboes*, 'irons'—both common in Elizabethan writers. The canalisation of the river in 1886 has since enabled steamers of 700 to 800 tons register to come up to the town; but the narrow channel and the heavy sea on the bar still render the port equally difficult to enter or leave. Nevertheless, the annual amount of British tonnage entering Bilbao exceeds that of any other foreign port in Europe with the exception of Antwerp. The exports, which include pig-iron, red wines, and wool, are numerous and unimportant, with the exception of iron-ore, on which the prosperity of the port depends. The total exports have

a value of over £3,000,000, nine-tenths iron-ore (mainly from Somorostro, 7 miles to the west), of which the bulk goes to Britain. The chief imports are coal, coke, codfish, timber, petroleum, tin, sugar, coffee, colonial goods, machinery, and metal wares, and have an annual value of £2,500,000—nearly half from Britain. The place, which is purely a trading town, prides itself on being kept exceptionally clean. Pop. (1887) 51,314. Bilbao was founded in the year 1300 by Diego Lopez de Haro under the name of Belvao—i.e. 'the fine fort'—and soon attained great prosperity. In the 15th century it was the seat of the most authoritative commercial tribunal in Spain. It suffered severely in the wars with France, first in 1795, and again in 1808, when 1200 of its inhabitants were slaughtered in cold blood. During the Carlist struggles Bilbao has stood two great sieges, Zumalacarregray here receiving his death-wound in 1835, whilst in 1874 the place was vainly besieged and heavily bombarded by the forces of Don Carlos for four whole months.

Bilberry. See WHORTLEBERRY.

Bil'bilis, an old Iberian city of Spain, 2 miles E. of the modern town of Calatayud (q.v.), in the province of Saragossa, chiefly celebrated as the birthplace of the poet Martial, but also famed for its highly tempered steel blades.

Bilcock. See RAIL.

Bilderdijk, WILLEM, a Dutch poet and philologist, was born at Amsterdam, 7th September 1756. While studying law at Leyden, and afterwards, when practising at the Hague, he devoted himself assiduously to literature and poetry. On the invasion of Holland by the French he repaired to Brunswick, and afterwards visited London, where he supported himself by lecturing and teaching. In 1806 he returned to Holland, where he was received as one who had done his country honour; and the newly-elected king of Holland (Louis Bonaparte) appointed him president of the new Institute at Amsterdam, and also made him his own instructor in the Dutch language. Bilderdijk afterwards resided at Leyden and then at Haarlem, where he died 18th December 1831. His contributions to poetic literature were very numerous; but though his lyrics especially contain many beauties, yet, with one or two exceptions, none of his poems display any remarkable originality, or any great wealth of imagination. He also made valuable contributions to the exposition of the older monuments of Dutch literature, and wrote a history of the Netherlands. He was strongly conservative in his tendencies, theological and other. His collected poems have been edited by Da Costa (Amsterdam, 1856-59).

Bile is a fluid secreted from the blood by the liver. One part of it is destined to serve in the process of digestion; the other to be eliminated from the system. It is coloured yellow in man, and in carnivorous and omnivorous animals; it is green in vegetable feeders. The primary cells of the liver (the hepatic cells) separate the bile from the blood of the portal vein, and discharge it into small ducts, which unite to form larger ones, and eventually the right and left hepatic ducts. The latter unite to form the common hepatic duct, which is soon joined by that of the gall-bladder (the cystic duct). This junction forms the common bile duct, which pierces the second part of the duodenum, and running obliquely in its wall for a short distance, opens on its mucous surface.

Bile is constantly being secreted, more copiously after food; while the duodenum is empty, most of it passes up the cystic duct into the gall-bladder where it is stored. But when the contents of the

stomach are carried past the opening of the common bile duct, a copious flow of bile takes place into the duodenum, where it is mixed with the food, in order to aid the further processes of digestion.

The composition of human bile is on the average of

Water.....	about 86 per cent.
Bile-salts.....	" 8 "
Mucin.....	" 2 "
Other organic substances.....	" 3 "
Inorganic substances (ash).....	" 0.6 "

The *bile-salts* (glycocholate and taurocholate of soda) are the most important constituents. If an animal membrane be wetted with a solution of these salts, it allows fatty substances to filter through it much more readily than if pure water or a solution of an inorganic salt be used; and this property aids in the absorption of fatty foods by the intestine. The bile-salts also assist in the emulsification, and to a certain extent, in the solution of fats. The *mucin* gives bile its viscid consistence. The other organic constituents include *fats* and *soaps*; *cholesterin*, chemically an alcohol, a crystallisable substance which is usually the chief constituent of biliary calculi or gall-stones (see CALCULUS); and the *bile-pigments*. The ash contains a considerable proportion of iron, derived, like the bile-pigments, from disintegrated red blood corpuscles (see BLOOD).

Human bile has the specific gravity of about 1026 (water = 1000), is of aropy consistence, with usually a yellowish-brown colour; does not readily mix with water, but sinks therein, and only after repeated agitation becomes diffused through the water, which then assumes a frothy appearance resembling soap-suds. Bile has a bitter taste and a faint musky odour. Besides aiding in the digestion of fats, bile stimulates the various muscular fibres of the intestine, and thus aids both the absorption and the propulsion of its contents; while the mucus it contains acts as a lubricant. It has also an antiseptic action, diminishing the putrefactive changes of the intestinal contents. Should, from any cause, the elements of the bile be in excess in the blood, or should the liver suspend the function of secreting it, not only is digestion imperfectly performed, but the general health suffers from the impure condition of the blood, and the patient is said to be *bilious*. On the other hand, the bile may be secreted, but its escape interfered with, and then its reabsorption will produce Jaundice (q.v.). See also the articles LIVER and DIGESTION.

BILIOUS ATTACK.—When the functions of the liver are temporarily interfered with, and particularly the secretion of bile diminished, most often in consequence of imprudence in eating or drinking, a *bilious attack* results. The liver, however, is rarely if ever affected alone, the stomach and intestines being also disordered; in most cases the stomach is probably the first to suffer. There are pain and discomfort in the abdomen, usually headache, and a yellowish discoloration of the skin and whites of the eyes; the tongue is furred and the appetite impaired, and the temper often becomes very irritable. Vomiting and diarrhoea often occur, and are in such a case salutary processes. The administration of a purgative is beneficial; and the food taken, if any, must be small in amount, simple, and readily digestible—e.g. milk with potash water, toast, bisuits, &c. See LIVER.

Bilge (sometimes spelled BULGE) is the part of the bottom of a ship nearest to the keel, and always more nearly horizontal than vertical. A ship usually rests on the keel and one side of the bilge when aground. The name of *bilge-water* is given to water which finds its way into the bilge or lowest part of a ship, and which, when not drawn off by the pump, becomes dirty and offensive.

Bilharzia (*Distomum* or *Gynocophorus hæmatobius*), a parasitic flat worm in the fluke or Trematode order, and belonging either to the same genus as the common liver-fluke (*D. hepaticum*), or to one very closely related. The most remarkable fact

Bilharzia:
a, male; b, female.

about this worm is the separation and relation of the sexes. In all other Trematodes the sexes are united, the animals are hermaphrodite, but here a grooved canal, formed from two folds of skin on the ventral surface of the larger male, contains the female. Pairs thus united are found in the portal and other vessels in the abdominal region, both in men and monkeys. They are especially abundant in boys, and cause hæmaturia and other troubles. These are mainly due to the inflammation caused by the deposition of the ova in the vessels of the mucous membrane of ureter, bladder, intestine, &c. They occur from Egypt southwards to the Cape. It is said that about half of the Fellah and Copt population of Egypt suffer from this parasite. The embryos are ciliated, but the life-history is not known. See FLUKE.

Biliary Calculi. See CALCULUS.

Bilimbi. See CARAMBOLA.

Bilin', a town of Bohemia, on the Bila, 5 miles SW. of Teplitz, and famous for its mineral springs, which, of a temperature of 60°, belong to the alkaline group, and are remarkably rich in native carbonate of soda. The waters and their various mineral constituents are exported in great quantities, and the springs are largely sought by sufferers from gastric, catarrhal, or scrofulous complaints. The town, since 1464 the seat of the princes of Lobkowitz, whose castle rises near by, is surrounded with basalt crags, and in its vicinity is a remarkable isolated clinkstone rock, 1754 feet high, Borzenberg or Biliner Stein. Pop. 6604.

Bill, in Natural History, the horny, toothless, and lipless jaws of birds. (*a*) *Structure*.—The foremost bones of the skull (mainly, the premaxillæ, but also the maxillæ and nasals) are elongated in variable degree and form, and are covered with a horny sheath. The same is true of the lower jaw or mandible, and the result is a bill. The upper and lower portions are generally equal, but the upper is longer in birds of prey. The edges, usually more or less sharp, sometimes (e.g. in goosander) exhibit saw-like notches not unlike teeth. In the majority of cases the bill is not sensitive, the distribution of nerves being restricted to a wax-like patch (the *cere*) at the base of the upper part of the beak. In aquatic birds, such as ducks and snipes, which feel for their food in the mud, this sensitive skin is carried forward almost to the point; and the bill of the woodpecker is also very richly supplied with nerves. The nostrils are usually far back near the cere, but often lie farther forward, most markedly perhaps in puffins.

(*b*) *History*.—No living birds have teeth. With the evolution of the class these structures have been lost. The fossil birds of America (*Ornithomorphes*) exhibit teeth, within sockets in *Ichthyornis*, simply in grooves in *Hesperornis*. But even in these forms the characteristic bones of the upper part of the bill—the premaxillæ—were toothless, and probably sheathed in a horny beak. The primitive bird *Archæopteryx* was also provided with numerous uniform teeth. From the beginning of the Tertiary Period onwards no toothed birds are found. Traces of teeth, however, still persist. Geoffroy St Hilaire (died 1844) observed small tooth-papillæ in the embryos of certain parrots, and this observation

has been repeatedly confirmed. The presence of the characteristic tooth-substance dentine has even been asserted. The tortoise tribe have also lost their teeth, and here again the presence of rudimentary teeth in embryos (*Trionyx*) proves that the toothless state is secondary. That birds get on well without teeth is evident enough, but it is difficult to give a physiological explanation of their absence. The very spongy character of bird bone, obviously inconsistent with teeth, the sharp antithesis between the skin structures of birds and those of reptiles, the disuse resulting from the developed parental care which supplies the young with food, the general nature of the nutrition, and the freedom from fighting which birds must at first have enjoyed, ought probably to be taken into account; but some deeper physiological reason is still required. This is peculiarly difficult when we recall the very varied nature and habit of toothless vertebrate animals—e.g. pipe-fish, toads, turtles and tortoises, birds, duckmole, echidna, ant-eaters, and some whales.

(*c*) *Relation to Function*.—The bill is chiefly used in seizing and dividing the food, but also for fighting, preening, nest-building, &c. It varies most with the nature of the food. It is hardest in birds which live on fruits, seeds, and flesh; sharpest in the birds of prey; more delicate in insectivorous forms; and softest in those which pick their food out of the mud. It is shortest in the graminivorous, and longest in the marsh-birds. In birds of prey the beak is hooked, and often notched; in fishing-birds it is usually very large; in those which catch flying insects the gape is particularly wide. Water birds often exhibit cross plates at the margins, between which the water taken in with the food is allowed to escape. Wallace has noted an interesting correspondence between the length of a humming-bird's bill and the depth of the flower-tube which it visits. Finally, it is worth noting that beaks sometimes exhibit (e.g. in fowls and sparrows) pathological variations, which closely resemble what in other birds are the normal forms. See BIRDS.

Bill, in its general acceptation, means a formal written paper or statement of any kind; originally, it was applied to any sealed document, being derived from Lat. *bullā*, 'a seal' (Middle English, *bille*; English Law Latin, *billa*). It has a number of technical applications, for which see the articles that immediately follow, as also PARLIAMENT; RIGHTS, BILLOF; INDEMNITY; EXCHEQUER BILLS; ATTAINDER.

Bill, in the criminal law of England, is the formal name of a written accusation of serious crime preferred before a grand jury. If that body by a majority finds 'a true bill,' the prisoner or party accused is thereupon tried upon an indictment before a petty jury, whose verdict determines his guilt or his innocence; but if the grand jury find 'no true bill,' the accused is at once set at liberty. In the latter event, however, other bills may be sent up against him. This whole procedure is more quickly and cheaply managed in Scotland by the system of public prosecutors, who take the responsibility of proceeding to trial without a preliminary public investigation. See GRAND JURY, INDICTMENT, PROSECUTION, TRIAL.

BILL, or BILL OF COMPLAINT, was the name given in the English Court of Chancery, prior to the Judicature Act of 1873, to the formal statement of the facts and prayer for relief submitted by a plaintiff to the court. This is now in every case a Writ of Summons (q.v.) and Statement of Claim (q.v.), and is not greatly different from a well-drawn summons and condescendence in the Scottish courts. In the United States, the bill consists of the statement, the charges, the interrogatories, the prayer of relief, and the prayer of process.

Bill-brokers are persons who, being skilled in the money-market, the state of mercantile and personal credit, and the rates of exchange, engage, either on their own account, or that of their employers, in the purchase and sale of foreign and inland bills of exchange, and promissory-notes. They are to be distinguished from discount-brokers, or bill-discounters, whose business consists in discounting or advancing the amount of bills of exchange and notes which have some time to run before they come due, on the faith of the credit of the parties to the bill. Thus a bill-broker might purchase a doubtful bill and discount it by means of his own credit. The distinction between them is not, however, in practice a very broad one. See BILL OF EXCHANGE, BROKER, PROMISSORY-NOTE.

Bill-chamber is a department of the Court of Session in Scotland which deals with summary business—so called because formerly both summonses and diligence or execution were for the most part commenced by a writ called a bill. These bills went to the whole court, but the necessity for them has been in most cases abolished by the reforming legislation of the 19th century. Since 1813 the bill-chamber is presided over by a single judge called the Lord Ordinary on the bills, and during the sittings of the Court of Session, the duty is taken by the junior or last appointed judge of the court; but in vacation-time, the business of the Bill-chamber is performed by a rotation of judges.

The business of the Bill-chamber consists of all matters of a summary nature; and generally all cases requiring the immediate interposition of judicial authority for arrestment of funds or inhibition of heritable property, for stay or suspension of diligence or execution. Applications for interdict or injunction, and for certain warrants necessary for the execution of process, are there at once made. Appeals from the inferior courts are now carried straight to the Court of Session; and the ordinary execution of decrees works automatically. The decision of the judge in the Bill-chamber may, with some exceptions, be brought under review of the Court of Session, and the judgment of the court itself may be appealed to the House of Lords. The proper jurisdiction of the Bill-chamber has been largely supplemented by statute. Thus, under all the bankruptcy statutes, sequestration may be obtained either in the Bill-chamber or in the local sheriff court; and on several important points in sequestration there is an appeal from the sheriff to the Bill-chamber. Again in vacation, the Bill-chamber exercises many of the powers of the Court of Session—e.g. in petitions for interim appointment of public officers, petitions under the Entail, Lands, Houses, and Pupil Protection Acts, &c. The Bill-chamber is open every lawful day from 10 to 4, and the papers lodged are twice in the day laid before the judge. See COURT OF SESSION, INTERDICT, CAVEAT.

Bill of Adventure is a writing by a merchant, stating that goods shipped by him, and in his name, are the property of another, whose *adventure* or chance the transaction is—the shipping merchant, on the other hand, undertaking to account to the adventurer for the produce. Generally, in commercial law, an adventure may be said to be a speculation in goods shipped under the care of a *supercargo*, to be disposed of by him to the best advantage, for the benefit of his employers.

Bill of Costs is an account stating in detail the charges and disbursements of an attorney or solicitor in the conduct of his client's business. It corresponds to the Account of Expenses in judicial proceedings, and the Business and Cash Accounts in Scotland. In both countries the solicitor may be

ordered to make out his bill if he claims any security on the client's property or papers. See COSTS.

Bill of Exceptions is a statement of objections, by way of appeal, against the decision of a judge who is trying a case with a jury in the Court of Session. The objection may be that the judge has misdirected the jury in point of law, or has improperly rejected or admitted evidence. The bill is argued before four judges, and if it is sustained, a new trial is ordered. The phrase was prior to the Judicature Act also used in England in the same sense, but is now merged in the 'motion for a new trial' (see TRIAL). In the United States, the phrase is used for a statement of the objections of either party to the ruling of the judge during the trial. Exceptions must be taken at the time, and should not be mixed up with supposed conclusions in matters of fact.

Bill of Exchange, a document purporting to be an instrument of pecuniary obligation for value received, and which is employed for the purpose of settling a debt in a manner convenient to the parties concerned. The original and simple purpose of a bill is to obviate the necessity of cash payments in the settlement of accounts between parties at a distance from one another. Thus, A and B are two merchants in London; and C is a merchant in Cadiz. A owes C £1000; and C owes B a like sum. Instead of A sending cash to C, and C to B, C draws a bill for £1000 upon his debtor A, and sends it on to B, who receives the amount from A; so that the transaction throughout is settled, without a farthing in money being sent from Cadiz to London, or from London to Cadiz. It is easy to see that a bill may, in a similar manner, pass through several other hands before it finally comes back to A, and is paid by him. Another simple idea of a bill is this: One person owes another £100 for goods, for which he is to have credit for three months. The creditor, however, not being able conveniently to be without the money for that length of time, gets from the debtor an obligation or bill bearing that the £100 is to be paid in three months. This bill, being a negotiable instrument, will be discounted by a banker, or other capitalist, who now stands in the position of the creditor, and receives payment when the bill is due. Thus, a bill of exchange performs two kinds of offices in commerce—it saves the transmission of coined money, and it enables creditors not only to fix down debtors to a day of payment, but to get the use of a sum equivalent to the debt (less a small discount) before it is properly due.

The origin of this important mercantile instrument is usually attributed to the Jews and Lombards, when banished from France and England in the 13th century. It is certain that hitherto no trace of such bills has been discovered either in the Roman code, or in any other system of ancient jurisprudence. The first notice of them in modern times occurs about the middle of the 12th century, and by the end of the 14th they had got into general use in all the commercial states of Europe. In England, from about the middle of the 14th century down to the time of James I., and for many years after, bills of exchange were restricted to the purposes of foreign commerce. What are called inland bills—i.e. bills drawn by and upon persons resident in this country—were not employed much earlier than the reign of Charles II., and even then they were regarded with distrust and jealousy by the English judges. Another restriction upon bills of exchange was, that the privilege of their use was confined to merchants. But all restraints on such instruments gradually yielded to the wants and conveniences of society, and now any one capable of making a contract can

be a party to a bill transaction, without regard to position, calling, or occupation. In Scotland, inland bills were put on the same footing with foreign bills, by an act of the Scottish parliament passed in 1696. Numerous enactments were passed from time to time, until in 1882 a measure became law, known as the Bills of Exchange Act, 1882 (45 and 46 Vict. chap. 61), which was intended to codify the existing law relating to bills of exchange, cheques, and promissory-notes. Besides doing this, the act introduces certain changes into the existing law, and in particular it assimilates in nearly every respect the laws of the three kingdoms in regard to bills or notes. Differences still exist in the following points: A bill does not in England, as it does in Scotland, operate as an assignation in favour of the holder of a debt due by the drawee to the drawer; the act does not alter the former rules as to bankruptcy in Scotland, nor in regard to the sexennial prescription or limitation, and the summary methods of enforcing payment, which continue to differ to some extent in each country; and in Scotland consideration is not required to support a bill as it is for simple contracts in England. The laws relating to bills in the United States, and in the various British colonies, are similar to the English law.

A bill of exchange is defined to be a written and unconditional order, addressed by a person who is called the drawer, to another person called the drawee, desiring him to pay a certain sum of money to a specified person, or his order, or to bearer, within a certain time after its date, or after it is presented for payment, or on demand. If the drawee signs the bill in token of his agreeing to this request, he is called the acceptor. A *Promissory-note* (q.v.), though differing in form, is in all essentials equivalent to a bill. It is, in fact, simply a bill in which the drawer and the acceptor are identical. A bank-note is a promissory-note issued by a banker, payable to bearer on demand, and a bank *cheque* is a bill of exchange drawn on a banker. Subject to certain special provisions they are regulated by the same rules as other bills. For the constitution of the bill itself, no particular form of words is necessary, provided its characteristic qualities clearly appear on the face of it, as a pecuniary instrument and an unqualified order. A bill of exchange is only good for a certain sum in money; such an instrument for the delivery of *goods* or property other than money would not be a bill. But although no particular words are required in a bill or note, it is always advisable to adhere, as much as possible, to their customary form. The only restrictions in regard to amount are that no bills or notes can be issued or negotiated in Scotland for less than 20s. (8 and 9 Vict. chap. 38), and that notes for less than £5, payable to bearer on demand, cannot be issued in England, nor, except by bankers, in Scotland or Ireland.

Besides the other requisites mentioned, bills of exchange must be duly *stamped*. The regulations on this subject are contained in the Stamp Act, 1870, and are to be found in almanacs and other publications in common use. The omission of the stamp, or using a stamp of insufficient amount, cannot be subsequently rectified; the bill is altogether void, and the parties to it are liable to a penalty of £10. A bill payable on demand, however, which is only liable to a stamp-duty of one penny, may be stamped with an adhesive stamp subsequent to its issue, but the above penalties are still enforceable. The duties on bills drawn out of the United Kingdom are denoted by adhesive stamps, to be affixed by the holder of the bill before negotiating it.

The following is the usual form of an inland bill of exchange (for foreign bills, see below):

£100.

(Stamp.) Two months after date [or 'at sight,' or 'on demand,' or 'at — days after sight'], pay to Mr E. F., or order [or 'to me, or order,' or 'to bearer']. One Hundred Pounds, for value received. A. B.

To Mr C. D., Merchant, Bristol.

From this form it will be seen that there are usually three parties to a bill of exchange, these three being: (1) The *drawer* (A. B.); (2) the *acceptor* or *drawee* (C. D.), to whom the order is addressed; and (3) the *payee*, or party in whose favour the bill is drawn, and who is entitled to receive the contents (E. F.). The transaction, however, may be simply between the drawer and acceptor, without the interposition of a third party; and there are other modifications and changes of form, according to the circumstances of the case, and the mode in which it is desired to have the bill negotiated. The bill being thus in proper form, and duly authenticated, is then presented for acceptance, which may be defined to be the act by which the drawee evinces his consent to comply with, and be bound by, the request contained in the bill of exchange directed to him; or, in other words, it is an engagement to pay in money the bill when due. Acceptance in the case both of inland and foreign bills of exchange must now be in writing on the bill, and signed by the acceptor, or some person duly authorised by him; the mere signature of the drawee, without any additional words, being sufficient. There are certain precautions to be observed before accepting. The drawee should, upon presentation for acceptance, and before he accepts, assure himself that the signature of the drawer is genuine, and that there has not been a fraudulent substitution of a larger sum than that originally inserted in the bill by the drawer. And if the drawee accept a forged bill, or a bill for a larger amount than that originally named by the drawer, he will nevertheless be liable to pay a *bona-fide* holder. There is also acceptance *supra protest*, which takes place where, after a bill has been protested for non-acceptance, but not before, any person, not already liable on the bill, may accept it *supra protest*, which acceptance is so called from the manner in which it is made. Where the drawee of a foreign bill cannot be found, or is not capable of making a contract, or refuses to accept, this description of acceptance is frequently made in order to save the credit of all or some of the parties to the bill, and prevent legal proceedings. In this country it is called an acceptance for the honour of the person or persons for whose use it is made, and in France an acceptance *par intervention*. The drawer or indorser of a bill may insert in it the name of a person to whom the holder may resort in case of its non-acceptance. In place of simply assenting to the order, the drawee may *qualify* his acceptance by making payment dependent on the fulfilment of a condition, as 'the delivery of bills of lading.' An acceptance may also be qualified as to the amount or currency of the bill or the place where it is payable. An acceptance 'payable at Coutts' Bank' would be general, but 'payable at Coutts' Bank only' would be a qualified acceptance. It must be observed that while the acceptance or indorsement may be qualified, the bill itself as drawn must be an unconditional order.

The bill as a negotiable instrument being thus complete in all its parts, may either be held by the drawer or other payee till due, when it is presented for payment to the acceptor, or it may at once be transferred by *Indorsement* (q.v.), the indorsee taking it for its value at maturity, and in the meantime cashing or discounting it to the holder. There may be a succession of indorsees, the last of whom is entitled to payment; and to

him all the other indorsees, as well as the drawee and drawer, are bound. Like the acceptance, the indorsement may be qualified or conditional, and it may also be *restrictive*, as 'pay A. B. only,' thus prohibiting the further negotiation of the bill. An indorser may also add the words 'without recourse,' so as to negative his own responsibility to the holder. This method of disposing of bills without a concurrent obligation by indorsement is better known and more practised in the United States than in England. Instead of discounting his bills in the usual form through a banker, a merchant in New York will sell his bills to a broker or dealer in this kind of instrument, the price paid being according to the state of the money-market and the creditworthiness of the acceptor. In such cases, the purchaser stands in the place of the drawer, undertakes all risks, and as custodian of the bill has the power of legally exacting payment.

When the bill arrives at maturity, that is, on the day when its payment is due, it must be presented for payment to the acceptor at the place or address mentioned in the bill; if none is mentioned, then at his place of business or residence. If the holder fail to duly present, the drawer and indorsers will be relieved of liability; even the known death or bankruptcy of the acceptor will not excuse presentment for payment. It may, however, be dispensed with if the acceptor is a fictitious person or is not bound to pay the bill, if the parties expressly waive presentment, or if, after reasonable diligence, the acceptor cannot be found.

When the bill is not payable on demand or at sight, three days of grace are added to the currency of the bill, on the last of which the bill becomes payable. Should the last day of grace fall on a common-law holiday, as Sunday, Christmas-day, or Good Friday, or a National Fast or Thanksgiving Day, the bill is payable on the preceding day; but if the last day of grace is an ordinary statutory bank holiday, the bill is due on the succeeding business day. If the acceptor is unable to pay, he may endeavour to arrange for a *renewal* of the bill—i.e. the drawing of a new bill with an extended currency. Failing such an arrangement, if the bill is not paid on presentment, the holder must give immediate notice of its dishonour to the drawer and indorser, from whom he can then claim payment. To preserve this recourse, it is not necessary to note or protest the bill, this act being now necessary only in the case of foreign bills, and, in the case of inland bills, as a preliminary to acceptance or payment for honour, or to preserve the right of summary diligence in Scotland. The acceptor, as primary obligant, may then be proceeded against in a very speedy form in England under the Summary Procedure Act, 1885, and in Scotland by the still more direct method of summary diligence, without further action, under the old statutes of 1681 and 1696.

By the Statute of Limitations (see LIMITATION) in England, and Prescription (q.v.) in Scotland, bills and notes (except bank-notes) become of no effect in six years after their due date, but the creditor may still recover on the original claim in satisfaction of which he received the bill.

ACCOMMODATION BILL. A bill in its legitimate sense is a document constituting a debt, and as such is beneficial to all parties connected with its negotiation. A owes B £100. A cannot conveniently pay the amount, while B is in need of it; B draws on A, and C (a banker) discounts—i.e. for a consideration pays the amount to B. B thus gets his money at once, A obtains time, while C makes a profit for advancing. These facilities have had the effect of inducing bills to be resorted to

for raising money where no value is given, and in which one party gives the use of his name for the *accommodation* of another. In the above case, for example, let us suppose that A does not owe B, but yet accepts B's draft. If C discounts the bill, it is immaterial whether he knows that A has got value or not—as an onerous holder, he can compel payment from A if B cannot pay the bill. But if merely in B's hands, the amount is not recoverable from A if the latter can prove that no value was received by him. Accommodation bills, being a simple and easy way of raising money on credit, often give rise to fraud and rash speculation, and many attempts have been made to suppress the system; but it is difficult to do so without unduly interfering with the negotiation of *bona-fide* bills.

FOREIGN BILL OF EXCHANGE is a bill which is either both drawn and accepted abroad; or drawn by a person residing abroad on a person in this country, or the reverse. The risk of miscarriage to which these bills are liable in their transmission to distant countries has given rise to the custom of drawing them *in sets*; that is, writing out two or three of the same form and tenor, and transmitting them to the payee by different channels, so that if one or two of the individuals of any set are lost, the other might reach its destination. The first of the set that is presented and accepted is alone entitled to payment, and payment of it discharges the acceptor; but foreign bills, of course, may also be drawn singly. The following is the usual form of a foreign bill:

£1000.

JAMAICA, 2d January 1887.

Fifty days after date pay this First of Exchange (second and third of same time and date unpaid) to the order of A. B., One Thousand Pounds sterling, value received. C. D.

To E. F., London.

If a bill be drawn in this country upon a correspondent abroad, or a foreign house, it must be stamped; and when drawn abroad, it must be stamped by the holder, before he can present it for payment, or indorse, transfer, or otherwise negotiate it within the United Kingdom (Stamp Act, 1870, sect. 51). Formerly, a bill drawn or payable in Scotland or Ireland, was foreign in England; but such bills are now inland, and the same regulation extends to the islands of Man, Guernsey, Jersey, Alderney, Sark, and adjacent islands (Bills of Exchange Act, 1882, sect. 4). The same act, sect. 72, provides that the liabilities of the drawer, the acceptor, and indorser shall be governed by the laws of the countries in which the drawing, acceptance, and indorsement respectively took place. The duties of a holder are determined by the law of the place where the act is to be done, and the due date depends on the law of the place where the bill is payable. Thus, a bill drawn in Paris or Berlin on London, is entitled to three days of grace, but a bill drawn in London on either of these places has no days of grace, these not being recognised by the laws of France or Germany. If a foreign bill is dishonoured by non-acceptance or non-payment, it must be duly protested, or the drawer and indorsers are discharged. In the case of foreign notes protest is not necessary, but it is always advisable if the makers of the note are to be sued abroad, as the law of the foreign country may require protest. Except in a few points, the laws of most commercial countries agree with those of the United Kingdom in regard to bills. See Byles, *On Bills* (1885); Chalmers, *On Bills of Exchange* (3d ed. 1887).

Bill of Health, a certificate or instrument, signed by consuls or other proper authorities, delivered to the masters of ships at the time of

their clearing out from all ports or places suspected of being particularly subject to infectious disorders, certifying the state of health at the time that such ship sailed. A *clean* bill imports that at the time the ship sailed no infectious disorder was known to exist. A *suspected* bill, commonly called a *touched* patent or bill, imports that there were rumours of an infectious disorder, but it had not actually appeared. A *foul* bill, or the absence of a clean bill, imports that the place was infected when the vessel sailed.

Bill of Lading is a receipt from the captain of the vessel to the shipper (usually termed the *consignor*), undertaking to deliver the goods—on payment of freight—to some person whose name is therein expressed, or indorsed thereon by the consignor; and the delivery of this instrument—independently of the actual delivery of the goods—will suffice to transfer to the party so named (usually termed the *consignee*), or to any other person whose name he may think fit to indorse thereon, the property in such goods; and by the Bills of Lading Act, 1855, it is provided that every consignee and every indorsee shall have transferred to him all rights of suit, and be subject to the same liabilities in respect of the goods as if the contract had been made with himself. The bill of lading is thus a negotiable instrument, subject to rights of stoppage *in transitu*, liability for freight, &c. It is also provided that every bill of lading shall be conclusive evidence of the shipment made. Bills of lading are thus the proper evidence of the contracts of a 'general ship'—i.e. where the ship is not chartered wholly to one person, or where the charterer takes sub-freights. They are made out in three copies; one of which is retained by the shipper, another sent to the consignee, another left with the master. A 'mate's receipt' is generally given until the more formal bill of lading is made out. The bill mentions the name of the master, the destination of the ship, the goods, the consignee, and the rate of freight (see also the article **SALE**). In the United States, a bill of lading is an instrument of twofold character: it is an acknowledgment of receipt by the master of the vessel, and it is a contract to carry safely and deliver. Its *prima facie* legal effect is to vest the ownership of the goods consigned in the consignee.

Bill of Mortality is a return of the deaths within a certain district, specifying the diseases, and giving a progressive view of the age at death. Such were the mortuary tables of Geneva, the Northampton and Carlisle tables, on which much of the business of life-insurance has been founded. The London bills were begun after a visitation of the plague in 1592, and continued by the company of parish clerks till shortly after the Registration Acts of 1840, being superseded by the Registrar-general's returns. The material for the returns was obtained by persons called 'searchers,' and the system was one of disgraceful inaccuracy and systematic imposition. The common expression, 'within the bills of mortality,' is a local term relating to an area which gradually increased with the growth of London, but defined under municipal arrangements which no longer exist. See **LONDON, VITAL STATISTICS**.

Bill of Sale is, in the law of England, a formal deed assigning personal property. It is the usual mode of transferring ships, and in the case of a registered ship it is necessary to follow the form provided by the Merchant Shipping Act. But in the case of other personal property, absolute bills of sale are rarely used except on a sale under execution by the sheriff. As mercantile securities, on the other hand, over stock in trade, household furniture, movable machinery, cattle, &c., bills of

sale are in England of enormous importance. Contrary to the principle of Scots law, that the property of movables can only be transferred by delivery, and hence that an effectual security over movables can be created only by possession, the English common law has recognised as effectual mortgages or bills of sale over movables which are left in the possession of the debtor. This led to great frauds on creditors, and the legislature has interfered in 1854, 1878, and 1882, to require public registration and other safeguards in the case of such securities. Registration must take place within seven days, otherwise the security is bad as regards goods left in the actual or apparent possession of the grantor. By the last act, bills of sale must henceforward have a schedule containing an inventory of the personal chattels assigned; must be attested by witnesses, else they become void; those given for any sum under £30 are void; and when goods are seized, they are not to be removed or sold until the expiration of five clear days. This act does not apply to Scotland or Ireland. In Scotland the device of an absolute sale, followed by a lease in favour of the debtor, has sometimes been followed. Wherever the latter obtains the full rights of a purchaser, even although only for the purposes of security, he is protected against the bankruptcy of the seller by the Mercantile Law Amendment Act, 1856, which entitles the purchaser, who has given value, to enforce delivery of goods sold from the bankrupt's estate. In Scotland, however, the common law as regards securities over movables has fallen into a state of uncertainty, and declaratory legislation is urgently required in the interests of trade.

In the United States there is no distinction between grand and ordinary bills of sale. The effect of such bill is to transfer the property in the thing sold. By an act of congress of 1793 every sale or transfer of a registered ship must be accompanied by a bill of sale setting forth at length the certificate of registry. But now a contract to sell, accompanied by delivery of possession, is sufficient.

Bill of Sight is an entry of imported goods of which the merchant does not know the quantity or quality. This is permitted to save time by the Customs authorities on sworn information. The bill must be made perfect in three days by indorsing the particulars required for warehousing, payment of duty, or delivery free of duty. If the entry is not completed within a month, the goods are sold.

Bill of Store is a license from the Customs authorities to re-import British goods formerly exported. Such goods are generally regarded as foreign goods unless re-imported within ten years from exportation, and unless belonging to the original exporter. Bills of store, however, are not given by the Customs regulations for corn, grain, meal, flour, and hops.

Bill of Victualling, or **VICTUALLING BILL**, is a list of necessary stores shipped from the bonded warehouse, or for drawback on board vessels proceeding on oversea voyages. It is made out by the master and countersigned by the collector of customs, the object being to prevent frauds on the revenue. Stores not on the list are liable, under the Merchant Shipping Act, 1883, to be destroyed. In the case of ships sailing in ballast, the bill of victualling acts as the certificate of clearance.

Billardiera, or **APPLEBERRY**, a genus of twining Australian evergreen shrubs of the natural order Pittosporaceæ. The fruit is generally bluish when ripe, and is eatable, although not destitute of a resinous character which prevails in the order. Some species are cultivated in greenhouses in Britain.

Billaud-Varenne, JEAN NICOLAS, one of the Terrorists in the French Revolution, was born at La Rochelle, 23d April 1756. From 1785 an advocate in Paris, he soon joined the Jacobin club, and became one of the leaders of the revolutionary movement. He took an active part in the September massacres, and distinguished himself in the Convention for his violence against the king and the royal family, and his general unfeeling cruelty. During the Terror he was president of the Convention and member of the Committee of Public Safety, and it was mainly at his instance that the Duke of Orleans, the queen, and a host of other victims, were arraigned before the fatal Revolutionary Tribunal. He joined in the end in bringing about the fall of Robespierre, but could not ward off his own condemnation to be transported to Cayenne (1795), where he lived about twenty years, rejecting the pardon offered by the First Consul. In 1816 he went to New York, but was coldly received, and then sought an asylum in Hayti, where he died at Port au Prince, June 3, 1819.

Billet, in Architecture, an ornament belonging to the Norman style. It was formed by cutting a moulding—generally a round moulding—into notches, so that the parts left resembled billets of wood. When used in several rows, the billets and

Billet.

empty spaces are placed interchangeably, as in the accompanying illustration.

Billet, in Heraldry. Billets are small oblong figures, sometimes taken to represent pieces of wood, sometimes letters. A field or charge strewn with an indefinite number of billets is called *Billey* or *Billettee*.

Billeting, or **CANTONING**, is a mode of feeding and lodging soldiers and their horses by quartering them upon the inhabitants of a town. As this system obviates the necessity of carrying food, forage, fuel, and camp equipment, it is resorted to as much as possible during a campaign, especially in its earlier stages, when collision with the enemy is not imminent, and therefore concentration has not become necessary. One or two men or the same number of horses are billeted for several nights on each hearth or family, which may be taken as four or five persons; for a single night the number per hearth would be greater. Billeting is also used on the Continent during the army manoeuvres, as many as nine men and three horses being allotted to each hearth, but the food and forage provided by the commissariat. In the United Kingdom the system has always been most unpopular, from the time when monarchs were wont to quarter their troops on the monasteries, and later when soldiers compelled the inhabitants of towns to receive and support them, the authorities being either unable or unwilling to interfere. The civil population naturally resented billeting, and one of the provisions of the *Petition of Right* (1628) was directed against the practice. The *Mutiny Act*, passed for the first time in 1689, declared that no housekeepers should be compelled to accommodate soldiers except on a recognised and fairly administered system. The chief civil magistrate of a town, on requisition from the military authorities, quartered the soldiers on the inhabitants as fairly as he could. This continued, in England, until 1745, when the liability to provide billets was limited to certain traders, and has so continued

ever since; but the alteration was not made in Scotland until 1857.

The *Army Act* of 1881 enacts that only the keepers of public-houses of any description, if licensed to sell beer, wine, or cider to be drunk on the premises, are liable to have soldiers billeted on them, and livery-stable keepers to take in troop horses. The exceptions are canteens, and houses kept by foreign consuls or Vintners of the city of London. The prices to be paid for food, forage, and accommodation are fixed for each year by the *Army Annual Act*. Before the present barracks were built at the headquarters of each regimental district, it was usual to billet militia, when called out for their month's training, in some convenient town, but this is no longer necessary. The cases in which billeting is resorted to in the United Kingdom are either when troops are called out in aid of the civil power, or when mounted troops are marching for several days; but whenever practicable, they would be lodged in barracks, and dismounted troops are always moved by rail or sea for any distance exceeding one day's march. The order for the march is the authority for drawing billets. It is issued by the Secretary of State for War, and specifies the exact number of men and horses for which billets may be drawn, and the dates on which they are to be at each town. This document is called a 'route.' A billeting party of two or three non-commissioned officers precedes the main body by one day's march, and presents the 'route' to the billet-master (usually the chief constable) at the first halting-place. This official has a list of persons liable to have soldiers billeted on them, and from it he selects those whose turn it is to take them. The men and horses are told off to their billets by the billeting party in order that no delay may arise when the main body enters. After its arrival, the soldiers go to the houses on which they are billeted; all those belonging to one troop being quartered as near together as may be, for convenience of muster, and the horses near the men. The licensed victualler is bound to provide each billet-holder with food, drink, bed, and accommodation, either in his own house or somewhere near at hand, and the livery-stable keeper has to provide straw, hay, and oats of good quality for each horse. The officers visit the houses, to see that the men really have one hot meal per day, instead of taking the value of it in money. The soldier may demand facilities for cleaning his arms and accoutrements. The quartermaster of the regiment makes the payments. Disputes often arise between the innkeeper or others and the officers of the regiment, and there are provisions of the *Army Act* framed to prevent irregularities on either side, but especially to safeguard the rights of the innkeeper.

In the United States, a provision of the constitution specifies that no soldier shall in time of peace be quartered in any house without the consent of the owner, nor in time of war but in a manner to be prescribed by law.

Billiards (probably from old Fr. *billard*, 'a stick with a curved end'; in English, introduced as the name of a game, and made plural). The origin of billiards is uncertain. Some ascribe its invention to Henrique Devigne, an artist who flourished about 1570. It was brought into fashion by Louis XIV. (middle of 17th century), whose physicians recommended him exercise after eating. Others believe billiards to be of English origin. It is mentioned by Spenser (*Mother Hubbard's Tale*, 1591) and by Shakespeare (*Antony and Cleopatra*, circa 1607). The earliest description of billiards in English is in Cotton's *Compleat Gamester* (1674). The bed of the table was then made of oak; sometimes of marble. Slate beds were first used about

1827. The cushions were stuffed with flock: list was used later. India-rubber cushions were first manufactured about 1835. The pockets, called hazards, were at first wooden boxes, nets being employed soon afterwards. Each player pushed his ball with a mace (now corrupted into mace), made of heavy wood, and tipped at the broad end with ivory. The game played was the white winning game (single pool), five or three up. A player holing his adversary's ball won an end (or life); if he holed his own ball he lost a life (hence the terms winning and losing hazards). In addition, a small arch of ivory, called a 'port,' and an ivory peg or 'king,' stood on the table, and certain scores appertained to passing the port and to touching the king.

In 1734 French billiards first appears in Seymour's *Court Gamester*. It is there stated that port and king are now wholly laid aside. Maces were still commonly used, but cue-playing was permitted. Cues, however, had no tips until the beginning of the present century. French billiards was very like single pool, a hazard counting two, a miss one, and a coup three. The game was played twelve up.

The losing game, in which a player scored for a losing hazard, was also occasionally played. About 1775 the carambole game (now corrupted into cannon) is first heard of. A third ball, called the caram ball (etymology unknown), was introduced. Winning hazards and cannons counted to the striker, losing hazards against him; and a baulk (now first so called) compelled the next striker to play out of baulk, as at present. Early in the present century, the white winning and losing carambole game, now known as billiards, ousted all other varieties in this country. It is played on a table 12 feet by 6 feet, surrounded by cushions, and having six pockets, of no fixed size, one at each angle of the two adjacent squares which form the bed of the table: three balls, diameter $2\frac{1}{8}$ inches, are used. The French have long discarded pockets altogether, and play only a cannon game, with larger balls and a smaller table. The Americans added a fourth ball, and in their game cannons and winning hazards counted to the striker, and losing hazards against him. They then abolished the two side-pockets, in consequence of their interfering with cannon play (or, as the Americans still spell it, more correctly, carom). Of late years pocket-tables have been but little used in America, except for pool; and the size of the table has been gradually reduced to 10 feet by 5 feet; balls $2\frac{3}{8}$ inches in diameter. The four-ball game is now seldom played by experts, the three-ball French carom game having superseded it in match play. Each carom counts one; each miss, one; and the game is usually 34 up.

The championship of the English game has been held by John Roberts, senior; Wm. Cook; John Roberts, junior; and Joseph Bennett, each having held it several times. From 1885, however, John Roberts's (jun.) play was so superior to the play of all the other professionals that his claim was not called in question till 1898, when Charles Dawson challenged him to play for it.

Meanwhile considerable discussion had taken place about certain strokes in the game—viz., the 'spot-stroke' (where the red ball is holed from the spot, the player recovering position with his own ball to repeat the stroke *ad lib.*) and the 'push-stroke' (where the player's ball is gently pushed through the object-ball till it reaches the third ball and makes the cannon). This push-stroke was held by its opponents to be a 'foul.' The tables also had their pockets of varying widths, so that 'records' have to be taken with caution. The 'championship' table had the pockets 3 in. wide, instead of the regu-

lation $3\frac{3}{4}$ in. of ordinary tables, and the billiard spot was $12\frac{1}{2}$ in. from the top cushion instead of $12\frac{3}{4}$, making the game much more difficult than on ordinary tables. The rules of the game otherwise were in a state of great confusion. On account of the greatly increased popularity of this really scientific and beautiful game this was very unfortunate, and the Billiard Association finally framed a series of rules which came into force on October 1, 1898. Among other changes, these rules bar spot and push strokes, and provide a standard for the width and shape of the pockets.

It was under these new rules that the championship match of 18,000 up was played between Charles Dawson and John Roberts in March-April 1899, when Roberts was victor by 1814 points. Roberts's record break for the spot and push barred game was 679, made April 15, 1898; but this was beaten by Dawson on October 21, 1899, when he made 722 under the association rules.

While it is almost impossible to learn the game of billiards without practical lessons, we may give a few hints which will be found useful to beginners. The first important matter is to acquire as easy an attitude as possible in striking the ball. The player should stand with his body a little to the left of the line of stroke, the left foot in front with the toes just under the cushion and pointing towards the ball to be struck. The right foot should be about 18 inches behind the left, and at right angles to it. The body should be inclined forward, with the face full in front of the ball. The cue is grasped lightly with the right hand near the butt-end, the hand being almost directly under the elbow, while the left hand is extended on the table to form the bridge on which to rest the cue. To form the bridge, the points of the fingers and the ball of the thumb should rest on the table, the knuckles being raised about 2 inches or so and the thumb pressed against the forefinger to support the cue. The point of the middle finger should be about 8 or 10 inches from the ball. The cue should be held nearly parallel to the table and pointing to the centre of the ball, and in striking it should be drawn back several inches and sent forward with a free and even motion without jerk, allowing the tip to follow a little after the ball. For practice, place the ball on the centre spot of the balk-line and hit it straight up the middle of the table. If hit truly in the centre it will return from the top cushion over the centre spot. So much of the game depends on striking the ball fairly that this, simple as it looks, should be practised till it can be done every time. If hit with 'side'—that is, on either side of the centre—it will return to that side.

After acquiring ease and accuracy in striking the ball the beginner will find it much to his profit to study the 'half-ball' stroke, as on this and its modifications the foundation of the game rests. The half-ball stroke is made by aiming with the cue directly through the centre of the striker's ball to the edge of the object-ball. When this is done accurately the angle at which the striker's ball will glance off the object-ball is invariable, unless force, side, or screw be applied. There are certain positions on a billiard-table from which the half-ball stroke can be readily found. For instance, place the red ball on the billiard spot, and draw an imaginary line from its centre to the upper edge of either of the middle pockets; if the cue-ball is placed anywhere on this line, a half-ball hazard off the red can be made into the opposite top pocket. If the red is hit exactly a half-ball it will return off the top cushion straight down the middle of the table, and the strength used should be enough to bring it down to about the pyramid spot. Another half-ball stroke is when the red is on the billiard spot and the cue-ball in line with its centre and one of

the top pockets. The stroke is into the other top pocket. When the red is placed on the pyramid spot there is a half-ball hazard into either top pocket from the corner spots of the D. These half-ball strokes apply equally to cannons, and should be practised until the eye gets thoroughly accustomed to the angle, when the variations produced by the use of force and side may be studied. Another very important part of the game is 'screw.' This is done by hitting the cue-ball below the centre, and without allowing the cue to follow the ball, but stopping it with a jerk just as the ball is struck. The lower the cue-ball is struck, and the fuller it is aimed at the object-ball, the more screw will be produced. With screw, a ball may be made to come off the object-ball at any angle between the half-ball angle and the straight 'screw-back,' which is produced by aiming at the object-ball quite full, and striking the cue-ball as low as possible. The 'follow-through' stroke is used when the object to be reached by the cue-ball is nearer a straight line than the half-ball angle. It is done by aiming the cue-ball more or less full at the object ball, and, when near it, a little above the centre. The result is that the cue-ball follows the object-ball more or less in a straight line as it hits it more or less full. On these three strokes—half-ball, screw, and follow through—is based the entire game; but their niceties and innumerable variations and modifications must be studied under a teacher, although any good handbook will be found very useful by an apt pupil.

See works by Jos. Bennett (1876; a thoroughly good book for beginners), Wm. Cook (1866; new ed. 1877), Collender (New York, 1881), Garner (New York, 1880), Drayson (1889), Buchanan (1895), Broadfoot and others ('Badminton' series, 1896), and G. W. Hemming, *Billiards Mathematically Treated* (1899).

Billings, JOSH, the pseudonym under which Henry M. Shaw (1818-85), a land-agent at Poughkeepsie, New York, published facetious almanacs and collections of witticisms, the wit in which, however, was mainly due to their deliberate miss-spelling.

Billings, ROBERT WILLIAM, born in London in 1813, acquired, during a seven years' apprenticeship with John Britton, topographical draughtsman, a taste for and facility in the production of illustrations of historic buildings. Between 1838 and 1846 he produced illustrations on his own account of several churches and cathedrals, including his *Architectural Antiquities of the County of Durham*. The work, however, with which his name is permanently associated is his *Baronial and Ecclesiastical Antiquities of Scotland* (4 vols. 1845-52), with accompanying letterpress to its 240 illustrations. He wrote several works on architecture, and conducted a large business; amongst the buildings restored under his direction are the chapel of Edinburgh Castle and the Douglas Room in Stirling Castle, &c. He died 11th November 1874.

Billingsgate, a gate, wharf, and fish-market, a little below London Bridge, to the west of the custom-house. It was opened in 1558 as a landing-place for provisions; and in 1699 was made 'a free and open market for all sorts of fish.' The present handsome stone building was finished in 1874. The unpolished phraseology native, though not peculiar, to this quarter of London, has given rise to the proverbial use of the name.

Billington, ELIZABETH, a celebrated singer, was born in London about 1768. Trained by her father, a German musician named Weichsel, she appeared as an infant pianist in 1774; and in 1783, after a secret marriage with her singing-master, James Billington, she came out with brilliant success on the opera stage in Dublin. Returning to London in 1786, she was engaged at Covent

Garden at the then unheard-of salary of £1000 for the season. She appeared subsequently in Naples, Venice, Florence, and elsewhere, with the greatest applause. In 1799, her first husband being dead, she married a Frenchman, Felissent, but owing to ill-treatment she left him and returned to London, 1801, where she received nearly £4000 for six months, playing alternately at Covent Garden and Drury Lane. She retired from the stage in 1811, and died (1818) at her villa near Venice, not without suspicion of foul play from her husband. To a voice of great compass and the richest tone, trained in all the art of the Italian school, she added a fascinating personal beauty and grace.

Biliton, or BLITONG, an island in the Dutch East Indies, between the SE. of Banca and the SW. of Borneo. It is of round shape, about 50 miles in length by 45 broad, and 1855 sq. m. in area. To the north, which is hilly, the highest point rises 3000 feet. It is rich in iron, tin, and timber, and exports rice, trepang, edible birds' nests, seaweed, tortoise-shell, and wax. Its coasts are beset with rocks and islets. The best harbour is at Tandjong; Pandang is the chief town. Pop. 38,200, of whom over 100 are Europeans, and 10,000 Chinese, the rest mostly Malays.

Billom, a decayed town of Auvergne, in the French department of Puy-de-Dôme, 14 miles ESE. of Clermont. It was the seat of a university from 1455 to 1554. Pop. 3920.

Billon, a name (originally French) for a mixed metal sometimes used in coinage, consisting of gold or silver, with a large proportion of baser metal. For some small French coins, a mixture of four parts of copper to one of silver was used before 1810.

Bilma, a town of the Sahara, Central Africa, situated in 18° 40' N. lat., 14° E. long., on an oasis called the Wady Kavar. It is the capital of the Tibu country, important as a resting-place of caravans crossing the desert, but is a poor place.

Bilney, THOMAS, martyr, born about 1495, probably at Norwich, studied at Trinity Hall, Cambridge, and was ordained in 1519. He was opposed to the formal 'good works' of the schoolmen, and denounced saint and relic worship; and to these mild Protestant views he converted Hugh Latimer and other young Cambridge men. In 1527 he was arraigned before Wolsey, and on recanting, absolved, but was confined in the Tower for over a year. Stung by remorse, after two years of suffering, he began to preach in the fields of Norfolk, but was soon apprehended and condemned; and although allowed to receive the sacraments of the church from which he differed so little, he was burned as a heretic at Norwich, 19th August 1531.

Bilston, a town in South Staffordshire, situated on a rising-ground, about 2½ miles SE. of Wolverhampton, and forming part of its parliamentary borough. It has extensive iron and coal mines, iron-smelting works, iron-foundries for making machinery, besides works for manufacturing tinplate goods, japanned and enamelled wares, nails, wire, screws, and coarse pottery. It is the centre, indeed, of the hardware trade, and consequently a very busy place. Fine sand, adapted for metal-casting, is found here. Pop. (1891) 23,453.

Biluchistan. See BELUCHISTAN.

Bima, a seaport of Sumbawa, one of the Sunda Isles, and capital of a state of the same name, is on a bay of the north coast, 100 miles E. of Sumbawa.

Bimana (Lat., 'two-handed'), a term first employed by the Göttingen anatomist Blumenbach (1752-1840) to describe the human species in con-

trast to other mammals. The separate order thus designated was recognised by Cuvier (1749-1832), and by most of his contemporaries and immediate successors. But in 1863 Huxley pointed out in his work entitled *Man's Place in Nature*, that as far as the term *Bimana* was concerned, it was equally deserved by some of the higher apes. In ordinary civilised man it is indeed obvious that the foot does not grasp in the way the hand does, but this is largely a matter of use and disuse. Many men in all races have learned to use their big toes as if they were thumbs, even to the extent, in more than one case, of playing on the violin; in less civilised races, the foot is not unfrequently used in rowing, climbing, and handiwork; and our own schoolboys and sailors exhibit considerable power of foot-grip. Haeckel notes how a young infant can grasp a spoon with the big toe as with a thumb. In short, man is four-handed if he chooses. The title is now rarely used, and man and monkeys are zoologically united in the old Linnæan order—Primates. See MONKEYS.

Bimbia, a district on the southern slope of the Cameroon Mountains in Africa, and on the northern bank of the river Bimbia. Since 1884 it is part of the German protectorate. See CAMEROONS.

Bimetallism is the name given to a monetary system in which both gold and silver are on precisely the same footing as regards mintage and legal tender. At present, in the United Kingdom, gold to any amount can be brought to the mint and coined into sovereigns free of charge, and the legal definition of the pound sterling is a certain weight of gold of a certain fineness, &c.; and gold, and Bank of England notes representing gold, are the sole legal tender to any extent.

The silver coins of this country are at present only 'token' coins. The value of the silver of which they are made (even at the valuation before any depreciation of silver relatively to gold occurred) is below the nominal value—i.e. the silver in twenty shillings (reckoning silver as worth about 60 pence, or a quarter of a sovereign, an ounce) is not worth the gold in a sovereign. As a consequence the silver is coined only in limited quantities, and is legal tender only to the extent of forty shillings. This preliminary explanation is necessary, because it is often said in a loose inaccurate way that bimetalism exists *de facto* everywhere, because all nations use both gold and silver for coinage.

There is, however, a fundamental difference between standard coin and token coin. If by great discoveries of gold, or by the opening up of hoards in the East under civilising influences, the amount of gold brought to the mints were increased to a great extent, then there would follow a general rise in prices. This depends upon the principle that, other things remaining the same, an increase in the quantity of money will raise general prices. The only object of converting the gold into coins is to use the coins to spend, and the increase in spending power tends to force up prices. The theory is confirmed by the effects of the great discoveries of gold in Australia and California about 1850. Similarly, in the 16th century, when silver was standard money, the discovery of the rich mines of Potosi caused a great rise in prices.

But if under present conditions, in which no civilised nation coins silver to an unlimited extent, there were similar discoveries of silver, there would be no corresponding effect on prices. The only effect would be that silver would, reckoned in gold, become cheap or depreciated. The coinage, however, would not be increased, because the use of silver is strictly limited. If silver were a standard coin, then it would be coined in unlimited amounts, and when expended would tend to raise the prices of

commodities. The principle may be expressed thus: The quantity of standard money, other things remaining the same, determines the general level of prices, but the quantity of token money issued is determined by the general level of prices. When prices are high, *ceteris paribus*, more token money will be required as a circulating medium than when prices are low.

If we consider any particular country, the principal difficulty in the adoption of both metals as a joint standard is generally expressed by saying that the joint standard or double standard (to use the more familiar but less accurate term) would be in reality a fluctuating single standard. It is argued that, considering the variations in supply and demand of the two metals, variations must constantly occur in the relative market values of gold and silver considered as bullion. At the same time, it is said, if both are coined in unlimited amounts for unlimited payments, some definite legal ratio must be adopted at which they are to be coined and to circulate. If a contract for so many pounds can be fulfilled by the payment of either gold or silver, it must be assumed that in some way the equivalent amounts are determined.

But suppose, when large amounts have been issued at one legal ratio, the ratio for example at which gold coins are reckoned as equal to 15½ times their weight of silver, a disturbance occurs in the market ratio of the metals, such as it is alleged must occur with variations in supply or demand. Let it be assumed that silver becomes cheaper, so that the silver in twenty standard shillings is no longer worth one sovereign in gold, but only three-quarters. That means practically that any person can for three-quarters of a sovereign buy enough silver bullion to make into twenty standard shillings. Clearly under these circumstances no one would pay his debts in gold when by first exchanging it for silver, he would gain five shillings in the pound. On the other hand there would be a rush to melt down gold in order to get the cheap silver, and the gold would, if silver remained below the old legal ratio, be driven from circulation. Under the opposite conditions of silver becoming relatively dearer, it would be replaced by gold, and thus the conclusion is reached that the joint standard would be an alternating standard with the cheaper metal as the real standard at any time. This law, according to which the cheaper metal displaces the dearer, is known as Gresham's Law; and it is found, historically, that a very small difference between the market and the legal ratio will suffice in any particular country to drive the dearer metal from circulation. This theory has been repeatedly illustrated in the history of particular countries. Thus, in England in 1717, according to the ratio adopted by the advice of Sir Isaac Newton, gold was, compared with silver, overvalued about 1½ per cent., that is to say, it was so much more valuable as currency than as metal. Consequently the full-weight silver coins were withdrawn, and gold became the principal currency. In France, on the other hand, at the time of the great Revolution, silver was slightly overvalued, and thus became the principal currency, the gold being to a large extent driven from circulation.

The question then arises: What becomes of this dearer metal, and whence is the cheaper metal derived which must be coined to take its place? It is obvious that in any modern society, the gold or silver displaced will not be hoarded, nor is there any reason why the mere change in relative value should lead to a greater use of plate made of the dearer metal. Accordingly it seems inevitable that this dearer metal should be exported, in order to get the cheaper metal for coinage, for by parity of reasoning it cannot be drawn from hoards or plate

within the country. It is this consideration which is the foundation of the argument, that although one country alone might be unable to maintain both metals as legal tender at a fixed ratio, under a union of the principal commercial countries the system would be quite possible and perfectly stable. For, *ex hypothesi*, there would in this case be no place to which the gold, supposing it became dearer, could be exported, or from which silver to take its place could be obtained. Again, if under these conditions any disturbance in the ratio occurred, (supposing it possible) to the advantage, for example, of gold, the gold would be driven from circulation and converted into bullion. Thus there would be a great increase in the supply of gold, and a corresponding increase in the demand for silver, and it is maintained that the old ratio would at once be restored. This process of reversion to stability is known as the *compensatory action of the double standard*, and is the counterpart of Gresham's Law in the present controversy.

If, then, the possibility of international bimetallism on a conventional basis is granted, it is requisite next to inquire into the advantages of the proposed system, for in currency above everything, the maxim *quiescit non movere*, to let things alone, is held to be sound. The advantages claimed are twofold. In the *first* place, it is argued that if the main work of standard money is in the future thrown upon gold, there must be a great fall in prices from the level to which the world had been accustomed with both metals as standard money. It is alleged that the fall in prices that has actually taken place since 1874, is mainly due to the substitution of gold for silver as the standard by Germany and other countries, because, taking the world as a whole, the amount of gold has not sufficed to keep up the level of prices. It is further argued that having regard to the increased use of gold for the arts and the diminished supply from the mines, this fall in prices will continue, or that there will be a continuous appreciation of gold, with a constant increase in the real burden of debts, and a disturbance of the real meaning of contracts and great friction in the adjustment of customary retail prices.

The term *appreciation*, as applied to gold, requires some explanation. If gold is the standard of value, it may be thought that its own value cannot change, just as a foot measure always remains of the same length—that a sovereign of full weight must always remain of the same value. But it is one thing to appoint by law that a certain amount of gold shall be coined into a certain number of sovereigns, and quite another to suppose that these sovereigns shall always exchange for the same amount of wealth. If, on the whole, a sovereign purchases more than it did, from whatever cause, that constitutes an appreciation of gold. An appreciation of gold is thus the same thing as a general fall in prices.

Seeing that the number of purchasable commodities is practically infinite, it is of course not easy to say even that a general fall is taking place, and it is still less easy to measure exactly the extent of the fall. For some commodities may be rising whilst others are falling. The general method adopted is to take certain important commodities as fairly representative. Thus the *Economist*, in its annual review, takes twenty-two commodities and compares their price with the price which was the average between 1845-50. Taking each of the average prices for that period as 100, the total would be 2200. In any subsequent year the actual change in price is worked out in these 'index numbers,' as they are called. Thus suppose during the given period the average price of wheat had been 60s. a quarter, and in some other year it

became 30s., we should have to change the index number from 100 to 50, that is, under it or half. If in adding up the total of the index numbers in any year we find a rise has taken place, then it is assumed this fairly measures the general rise in prices. It may be interesting to quote some of the principal changes in the 'index numbers.' A fluctuating rise took place from 1850 up to 1864 when the index numbers became 3787. This is equivalent to saying that on the articles taken there was an average rise of about 72 per cent. It would, however, obviously be a mistake to argue that all prices must have risen to that extent, especially when we consider that owing to the American civil war the price of cotton was abnormally raised. From 1864 to 1871 there was a fluctuating fall in prices, the index numbers in the latter year being 2590. Then a rise took place, the numbers in 1872, 1873, 1874, being respectively 2835, 2947, 2891. Thus in these years of inflation, as they are often termed, though there was a rise of about 31 per cent. on the original 'index numbers,' there was a still greater fall from the numbers of 1864. From 1874 there was a steady and rapid decline, until on 1st January 1886 the aggregate 'index number' was only 2023, which was lower than the original number, and lower than that of any year subsequent to 1850. It is this very remarkable fall in prices that constitutes the appreciation of gold, and it is maintained by bimetallists that if silver were used to supplement gold as standard money, the fall in prices would be checked, and that for the future the general level would remain more steady. The fall in prices has apparently affected agriculturists more than any other class, because many of the charges are fixed for comparatively long periods, and thus expenses cannot be adjusted to the new level of prices very readily.

Secondly, the adoption of conventional international bimetallism (for that is the only system practically proposed) is advocated not only as a partial remedy for the appreciation of gold, but also as a preventive of fluctuations in the relative values of gold and silver. It is said that the recent depreciation of silver, caused by the monetary disturbance, has injuriously affected our trade with silver-using countries, and that in effect this depreciation has acted like a protective duty on imports into such countries, and a bounty on their exports. To these statements of alleged facts it is replied generally that our exports to the East, or silver countries, have largely increased, and that the exports from the silver countries, such as Indian wheat, have been really stimulated by other causes—e.g. railways and reduced freights by sea. It is, however, undeniable, that if gold prices on this side had remained at their old level, whilst at the same time silver had depreciated, the effects on our eastern trade would be accurately described by the analogies of a protection duty in the one case and a bounty in the other. So far, however, as the gold prices of commodities have fallen in the same degree as silver, no such stimulus or restraint appears to take place. A Manchester merchant may just as well sell to India for the same silver as before, even although it produces only thirty per cent. less gold, as sell to gold-using countries for thirty per cent. less gold, directly without the intervention of silver. Similarly, an Indian exporter has no advantage from cheap silver if he obtains for his exports thirty per cent. less gold wherewith to purchase silver.

Here, however, the question arises whether the depreciation of silver has not directly, to a large extent, caused the fall in gold prices. It is generally admitted that the effect of a bounty is to lower prices in the foreign country, and protective duties operate indirectly in the same way; and similarly, it is maintained (especially by M.

Cernuschi) that the depreciation of silver has lowered all prices measured in gold.

It will be observed that both of these advantages claimed for bimetalism depend upon questions of fact; and the difficulty in obtaining information was the chief reason for the appointment of the Royal Commission in 1886. No one, however, denies that if by any means the relative values of gold and silver could be fixed, it would be beneficial to the world at large. Mere fluctuations are certainly an evil. The possibility of thus fixing and maintaining a ratio receives strong practical support from the fact that for seventy years, in spite of great variations in the relative amounts of gold and silver produced, the existence of bimetalism in France, and the large use by other nations of silver as standard money, kept the ratio, apart from small variations due to exchange operations, at nearly $15\frac{1}{2}:1$. It may also be said that an international convention, once established, would not be broken in the same capricious manner as a purely political treaty; for it may easily be shown that every nation makes the agreement in the first place with its own subjects, and that by breaking the agreement it would injure them more than any one else. There is really not much more apparent reason why, once established, the system should be broken through, than if all the nations had adopted the same system of weights and measures. It is possible, of course, that the initial difficulties may be insuperable in spite of the extremely unsatisfactory condition of the present relations of gold and silver. At the same time it is difficult to suppose that the present state of things can continue.

The United States were compelled by the Bland Act to coin large quantities of silver every year; the Sherman Act (1890; repealed 1893) empowered the Treasury to increase its purchases of silver, but failed to maintain the ratio (see SILVER). The government of India also failed to maintain the ratio by stopping (1893) the free coinage of silver.

But any attempt to adopt gold as the sole principal standard throughout the world, would, in Mr Goschen's often-quoted opinion, produce a most disastrous monetary crisis, and thus the choice seems to lie between an international agreement on a reasonable basis, and the reliance on the self-interest of each particular nation to make no further change through dread of further evil.

It is impossible to even mention in a brief article all the points of controversy on the question of bimetalism. Until the recent great and rapid fall in the value of silver compared with gold, it was apparently believed that from some curious but beneficial natural cause the ratio would remain fairly steady, and for about seventy years the variations were very small. Accordingly, very little attention was paid to the question by economists, who for the most part were content with saying that it would be difficult for one country to maintain effectively a double standard. Again, when the depreciation set in, it was believed that it would be only temporary, but this belief has proved to be unsound.

The partial failure of the Latin Monetary Union to preserve an international *coinage*, ought not to prejudice the case of a bimetallic union like that proposed by the United States. The Latin Union, proposed in 1865 and accomplished in 1868, was essentially a treaty between certain countries (France, Belgium, Italy, Switzerland) for an identical *coinage* (apart from the mere stamp) to be received as legal tender in each country. It was only accidentally bimetallic, and no special provision was made for the unlimited coinage of either gold or silver.

It is impossible to obtain accurate figures either as to the production of gold and silver, or as to the extra demands made on gold and the extra supplies of silver thrown on the market since the demonetisation of the latter. There is, however, no doubt that the production of gold has decreased as that of silver increased, and that the demonetisation of silver has to some extent increased the supply of it as a commodity.

To understand the subject in its present bearings, the reader must refer to recent writers, and consult especially the Report of the Royal Commission. On the monometallic side may be mentioned Mr Fowler's *Appreciation of Gold*, Mr Giffen's *Essays on Finance*, and the papers published in the *Contemporary Review* by Mr Wells. On the other side much more has been written, since attack is always more productive than defence—e.g. various essays by H. Cernuschi, H. H. Gibbs, Grenfell, R. Barclay, S. Smith, &c.; a valuable historical work by the Hon. Dana Horton called the *Silver Pound*, and a *Treatise on Money, with Essays on Present Monetary Problems*, by Professor J. S. Nicholson, may also be mentioned. The best book for the statistics of the question is Soetboer's *Materialien*, translated from the German for the use of the Royal Commission, and published in America by Mr Atkinson.

Binary Theory, in Chemistry, takes cognisance of the mode of construction of salts. It assumes that all salts contain merely two substances, which either are both simple, or of which one is simple and the other a compound playing the part of a simple body. The best and most familiar illustration of the binary theory is common salt or chloride of sodium, NaCl, which is constructed of the metal sodium, Na, and the non-metal chlorine, Cl, and is at a glance seen to be a *binary compound* (a compound of two). In like manner, fluor-spar, or the fluoride of calcium, CaF₂, consists of the metal calcium, Ca, and the non-metal fluorine, F; and iodide of potassium, KI, largely employed in photography, of potassium, K, and iodine, I. Although this theory attracted much attention from 1837 to 1855, and was adopted by Liebig and other chemists, it never met with general acceptance, and has now been quite superseded. See ACIDS and SALTS.

Binche, a town of Belgium, in the province of Hainault, 10 miles E. of Mons, manufacturing delfware and lace. Pop. 10,104.

Bindraban. See BRINDABAN.

Bindweed. See CONVULVULUS.

Bingen, an ancient town of Hesse-Darmstadt, Germany, is charmingly situated on the left bank of the Rhine, 39 miles S.E. of Coblenz. Below the town is the celebrated *Bingerloch*, formerly a very dangerous point in the navigation of the Rhine, but in the year 1834 the sunken rocks were blown up. In the middle of the river stands the *Mäusethurm*, the tower of Bishop Hatto (q.v.). Nearly opposite Bingen, in the Niederwald, is the colossal statue *Germania*, erected 1877-83 to commemorate the war of 1870-71. Pop. 7627.

Bingham, JOSEPH, a learned English scholar and divine, was born at Wakefield in Yorkshire, September 1668. Educated at University College, Oxford, he was elected fellow in 1689 and college tutor two years later, but was obliged to resign his fellowship owing to an unfounded accusation of heresy in a sermon which he had preached in St Mary's on the meaning of the word 'Person' in the Fathers. He was at once, however, presented to the rectory of Headbournworthy in Hampshire, and here he commenced his laborious and learned *Origines Ecclesiasticæ, or Antiquities of the Christian Church* (10 vols. 1708-22). In 1712 he was

preferred to the rectory at Havant in Portsmouth, and in 1720 he lost all his property in the great South Sea bubble. He died August 17, 1723.

Binghamton, a flourishing city of New York, at the junction of the Chenango and Susquehanna rivers, 215 miles NW. of New York city. It is an important railway centre, and manufactures flour, engines, carriages, leather, and cigars. Pop. (1870) 12,692; (1890) 35,005.

Bingley, a town in the West Riding of Yorkshire, 15 miles WNW. of Leeds. It has worsted, woollen, cotton, and paper manufactures. Pop. (1861) 5238; (1891) 19,284.

Binney, THOMAS, D.D., LL.D., a Congregational preacher, born at Newcastle in 1798, in 1829 settled in London where he soon acquired extensive popularity. The new Weigh-house Chapel, near London Bridge, was erected for him by his hearers in 1833, and here he continued to labour with great success till 1869. He died 24th February 1874. Of his numerous writings the most popular was *Is it Possible to make the Best of Both Worlds?* (1853). See the *Lives* by Stoughton (1874) and Paxton Hood (1874).

Binoocular. See OPERA-GLASS, MICROSCOPE.

Binomial, in Algebra, is an expression which consists of two terms, separated by + or -, such as $x+y$, $ab-ed$. Monomial, trinomial, polynomial are the names given to expressions consisting of one, three, more than three terms. The Binomial Theorem is a method of expanding $(x+y)^n$ into a finite or an infinite series of powers of x and y , when n is a number either integral or fractional, positive or negative, rational or irrational; thus $(x+y)^n =$

$$x^n + nx^{n-1}y + \frac{n(n-1)}{1 \cdot 2} x^{n-2}y^2 + \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} x^{n-3}y^3 + \dots$$

It was discovered by Newton about 1666, and was first published in 1704 in the second appendix to Newton's *Optics*. That particular case of the theorem when n is a positive integer was known to mathematicians prior to Newton (e.g. Briggs and Pascal), and Newton himself gave no demonstration of the truth of his theorem. Many demonstrations have been given by subsequent mathematicians, but the validity of most of them has been called in question.

For more information regarding the Binomial Theorem, its applications and its developments, see Chrystal's *Text-Book of Algebra*.

Bintang, an island of the Dutch East Indies, 40 miles SE. of Singapore. Area, 454 sq. m.; pop. 18,000. Gambir, rice, and pepper are exported.

Bin'turong (*Arctictis* = bear-marten), a genus of carnivores in the civet section. Its resemblance to raccoons, beside which it used to be placed, is entirely superficial. It is a slow arboreal and nocturnal animal, partly vegetarian, indeed omnivorous, in its diet, with hank body, coarse dark hair, long tufted ears, and prehensile tail. There is but one species (*A. bin'turong*), found in India, Malay, Sumatra, and Java. It is easily tamed.

Binuc. See BENTE.

Biobio, the largest river of Chili, has a west-north-westerly course of about 220 miles, from near the volcano of Antuco in the Andes to Concepcion on the Pacific Ocean. It is 2 miles wide at its mouth, and navigable for 100 miles.—The river since 1875 has given name to a province with an area of 4158 sq. m., and a pop. of 122,729.

Biogenesis, as opposed to Abiogenesis (q.v.), is the name used by Huxley for the theory that living matter always arises by the agency of pre-existing living matter. See also LIFE, SPONTANEOUS GENERATION.

Biography is the artistic representation in continuous narrative of the life and character of a particular individual. It may be either a mere *curriculum vitae*, detailing only the historical sequence of the incidents of a man's life, or it may be an elaborate attempt at an analysis of his character, and at a complete reconstruction of the whole motives of his actions. To the former class the ancient examples of biography, as the *Lives* of Cornelius Nepos, mainly belong, while modern biographers have mostly aimed at the latter method. But of course the inward life is revealed in the outward, and even such a biography as the *Agricola* of Tacitus, with all its stately dignity and reticence, does give the reader some real insight into the character of the man. The main object of biography as now written is portraiture, and its success or failure mainly depends on the degree of truth and completeness with which the image is represented. The facts of a life may be fully and truthfully told without any adequate idea being given of the personality of the central figure, which is often revealed in small details that might well escape the notice of a biographer who lacked the eye to see them and their significance. Thus, as Dr Johnson points out, Sallust has not forgotten in his account of Catiline to remark that his walk was now quick and again slow, as an indication of a mind revolving with violent commotion. But indeed it could not be better put than it is by Plutarch, the prince of ancient biographers, in his 'Alexander,' in a passage aptly quoted by Boswell: 'Nor is it always in the most distinguished achievement that men's virtues or vices may be best discerned; but very often an action of small note, a short saying, or a jest, shall distinguish a person's real character more than the greatest sieges or the most important battles.'

It is hardly necessary to add that there is no more interesting department of literature than biography, that the most fascinating study of mankind has ever been and will ever be man himself, and this hardly less in the lyric or the occasional essay than in the formal biography or autobiography. 'I never look,' says Montaigne, 'upon an author, be they such as write of virtue and of actions, but I curiously endeavour to find out what he was himself.' The genuine lyric is a spontaneous and impassioned expression of an emotion of the writer, and its poetical value depends ultimately on the poverty or richness of his personality; while the essay, as understood by Montaigne, its inventor, and such masters in this form as Addison and Charles Lamb, owes no small part of its charm to the pleasing egotism by which hints as to the feelings and foibles of the writer are conveyed by the way to the sympathetic reader. The essay has now come to be so much a merely didactic medium that the personal equation in it has become inconsiderable, and we are apt to forget that in its simpler and perhaps more perfect forms it ever contained something of self-revelation, conscious or unconscious. Even such severe examples as the famous essays of Bacon, throughout which we scarcely find one word about the writer, yet really make up, as Dr Abbott points out, a kind of autobiography which tells the story of the intellectual and moral history of youth passing into age, and the student making way for the statesman.

Many lives are written in such eulogistic terms that they fail by default to give a truthful picture of their subject, while others, in their fear of being unlike life, deepen the shadows until the picture becomes equally untrue through its over-truthfulness. Thus, in the life of Carlyle by Mr Fronde, many critics accused its accomplished author of having given such undue prominence to

the disagreements between Carlyle and his wife as to distort completely the picture of the ordinary life of the pair; while Mr Froude's defenders maintained that he had but painted Carlyle as he would have painted himself, every wrinkle on the face truthfully represented on the canvas, and that his business was to describe the man as he lived, not as he should have lived. Again, a biographer may not understand the relative significance of things, and thus unconsciously give an untrue picture of his subject. Especially is this danger close to him when he has to deal with a time or a society in which he himself has not lived. It is difficult for him to breathe freely in another atmosphere than his own, and avoid anachronisms in feeling if not in fact.

A biographer must have an adequate knowledge of his subject and his surroundings. He must follow him in his controversies and his speculations, and must be able to weigh in the balance his abilities as well as his private virtues. Thus the best biography should be that written by one almost as great as his hero, skilled in the same things, with full sympathy and perfect knowledge, as the life of Dr Arnold by Dean Stanley, and Boccaccio's life of Dante—'a great man,' says Emerson, 'to describe a greater;' while the worst should be the production of the professional biographer, who is ready at a moment's notice to write to order lives of poet, philanthropist, or man of science alike. The latter part of the proposition is much truer than the former, which is indeed true, though not exclusively so, for it will hardly be maintained that Boswell was nearly as great a man as his hero, though he had insight enough to write the best biography in the English language; while from a merely literary point of view, some of the most effective biographies we possess were written by men of letters, lacking the special technical knowledge that might have been esteemed necessary. Southey's life of Nelson is admittedly one of the most perfect biographies in existence, yet the author tells us that he had to move among the naval terms like a cat among crockery. Indeed adequate insight and sympathy, with a fine sense for literary form, may make up a complete equipment for a biographer, for Walton's lives are absolutely perfect examples of biography, though the garrulous old angler could scarcely have understood the full significance of the great work of Hooker. There are few books in English of such abiding interest and excellence as Johnson's *Lives of the Poets*—a singularly happy combination of sympathy and intelligence, although at the same time a collection of lives of very varying values. Thus the lives of Pope and Dryden are as conspicuous for their goodness as those of Gray and Milton are for their badness, in one respect at any rate. That of Savage has the additional interest of casting a reflex light on the early struggles of Johnson himself, while yet he was without his Boswell. No less admirable are Macaulay's short lives of Johnson, Goldsmith, Atterbury, and Bunyan, written for the *Encyclopædia Britannica*; and Scott's volume of *Biographical Memoirs*—short, shrewdly sensible lives of Richardson, Fielding, Smollett, Goldsmith, Johnson, and others. Scott's lives of Swift and Dryden, forming the first volumes of complete editions of their respective works, still hold the field.

Most modern biographies are too large—they err by not selecting merely the significant. Perhaps it is true that near things look too large, and that the right perspective is only possible to the observer at some distance. The lives of the greatest men must teem with details that are quite ordinary and unimportant, and we gain absolutely nothing by

having these set down. Just as in the art of portrait-painting, it is relatively of but little importance how the accessories are filled in, so as the living look that made up the individuality of the subject has been caught. And if it requires a special gift of insight in a Velasquez or a Rembrandt to see so as to reproduce on his canvas the subtle something on which the expression of a face depends, so to the biographer there is the same necessity to see under the surface the hidden springs of character; while it cannot be doubted that his task—the moral diagnosis of motive—is infinitely the greater in difficulty. The biographer must be more than the mere realist who can photograph facts—he must be something of the idealist as well, for he has to create as well as reproduce; and we value a biography exactly in proportion as its author has succeeded in creating for us the character of a new man or woman to be added to our personal acquaintance. If, as has been said, every man's life is worth telling for something that there was in it of unique interest, it may be equally true that all the life save this particular part was not worth telling at all, and had better been left untold. Although undoctored human nature with its swarm of struggling and contending motives is always an interesting study—in its morbid no less than in its normal phases—yet the elaborate dissection of mere human frailty must ever be a wearisome and unprofitable pursuit. Man's spiritual aspirations cannot be fed upon mere clever character-analysis, and lives that had in them nothing high for humanity had better be soon forgotten. There are perhaps no books more really unprofitable to generous youth than those that are often put into their hands—the lives of men who have earned mere material success, and carved themselves fortunes out of the hard conditions in which they were born. Humanity in its onward progress will soon get past this point, and recognise that in the history of our race the real spiritual and ultimately material makers of the future were far more often men who seemed to fail completely in the struggle of life.

The lives of the great men who have helped to mould their times throw much light on contemporary history. The biographies of Cromwell, Frederick the Great, and Napoleon, broadly speaking, sum up great part of the public history of their times, but do no more for us than merely throw a side-light on its social history, which must be reconstructed by a wide and patient study of the conditions of life of the common people. Professor Masson's life of Milton is the largest life of an individual Englishman, but despite its ponderous learning and great accuracy, cannot be regarded as a model biography, overweighted as it is with an enormous mass of detail about contemporaries unjustified by anything but a round-about and indirect connection with Milton himself, who, spite of his poetical and even political importance, was not by any means the centre of the destinies of England. Carlyle's life of John Sterling, again, is an example of an almost perfect biography, and yet it is that of a man whose life was in some respects hardly worth writing at all. He was indeed a man of high aspirations and clear intellect, but beyond this there was scarcely anything very memorable in him, and the abiding charm of the book is due to nothing but the consummate art of the writer and his revelation of himself in sympathy with his subject. Mr Cross's life of George Eliot errs in the opposite direction. Here the biographer adopted the method of making the subject speak entirely by extracts from letters, with the very briefest possible connection of narrative. But by keeping himself so much out of sight, the writer only avoided

Seylla to fall into Charybdis, and succeeded in making a book dull and lifeless that should have been unusually full of interest.

Many biographies, by having a subject of too narrow interest, or by treating a subject in too narrow and special a sense, do not reach the level of a permanent place in literature, though they may have been treated with full knowledge, fine literary sense working within the conditions laid down, and even proper sense of relative proportion. Every year produces examples of biography which are doomed, spite of more or less creditable literary workmanship, to be soon forgotten, from the ephemeral importance to the world of their subjects, and the controversies in which they were involved. Each one, for example, of our hundred religious denominations has its heroes—all important to its own sectaries, but not necessarily of the slightest value to the infinitely wider world. The lives of these men are full of interest within the small circle of their personal influence, but they do not in the least touch the sympathies of readers outside it, unless they chance at once to be written with more than consummate literary skill, and to be revelations of figures with dimensions much beyond those of the usual church leader or pulpit orator. But unfortunately the hero of our religious biographies is not always a Wesley, a Chalmers, an Edward Irving, a Whitefield, or a Pusey, any more than the biographer is always a Southey, a Hanna, a Mrs Oliphant, or a Liddon. Similarly, there is hardly an eminent man of science, actor, musician, mere millionaire, or successful soldier whose life is not written often in his own lifetime, at more or less extravagant length, and with a more or less absurd overestimate of his relative importance. By no means the least really important of our biographies are our lives of 'illustrious shoemakers,' and those unknown village naturalists who so suddenly found themselves famous.

We have many lives, moreover, of very great inherent importance indeed, but which appeal to comparatively small circles of readers from the large demand they make upon the possession of special culture or knowledge. Such are many of our larger lives of philosophers, and those of artists and musicians. Excellent examples of the last are Crowe and Cavalcaselle's lives of *Raphael* and *Titian*, Spitta's *Bach*, Jahn's *Mozart*, Karasowski's *Chopin*, and Woltmann's *Hans Holbein*, all excellent examples of solid, conscientious, and exhaustive biography, but of too large proportions for the mere literary student.

All history is full of the materials of biography, though it is only in the narrowest sense true that history is nothing but an aggregation of the biographies of individuals. No little of the interest in ancient and modern histories alike depends on the pictures of men and women with which their pages are lightened up, and this we find in annalists like Livy and Tacitus, no less than in professed biographers like Plutarch and Suetonius. Perhaps no more living portraits were ever painted than those sketched in a few touches in the lurid colours of Tacitus. In the hasty sketch of the master we see far more than in the most finished painting by the dauber. Such books as Holinshed's *Chronicle*, Clarendon's *History of the Rebellion*, Burnet's *History of his Own Time*, and Shakespeare's historical plays, from the portraits of individuals they contain, have an additional interest that is only second to their historical importance. Indeed it is far more than a paradox to say that such works of creative fiction as the last are truer than the records of history themselves, for they are informed with a deeper inwardness than these, and do far more to create for us the actual living objective figures of history. Shakespeare's

Richard III. is not only a magnificent creation as the dramatic revelation of a matchless usurper, but it is so true a realisation of this working on a sound basis of consistent tradition that it satisfies, as Mr Gairdner tells us, the requirements of historical truth almost as much as any formal history. Shakespeare's historical figures are not puppets dressed in old clothes, but living and breathing men and women, and the bare historical details of their characters and lives have become fused in his glowing imagination and harmonised into consistent wholes stamped with the warm and actual impress of very truth. This is hardly less true of Macaulay's *History*, and still more of Carlyle's *French Revolution*, with its vivid portraits of even the minor figures flashed like instantaneous photographs upon the reader's brain. Again, books like D'Israeli's *Calamities of Authors and Quarrels of Authors* are full of rich material for the biographer, as are also such critical essays as those of Macaulay and Carlyle, hardly less than professedly biographic studies like Hayward's *Sketches of Eminent Statesmen and Writers*, and Bagehot's *Biographical Studies*.

One word must be said on the question of the biographer's reticence. Voltaire said, 'We owe consideration to the living; to the dead we owe only truth.' Doubtless this is true if the dead have slumbered long enough to be regarded somewhat impersonally even by their own descendants, but no language is too strong to reprobate the conduct of those writers of biography or autobiography who ruthlessly tear open unhealed wounds and bridge their malignant malice across the separating grave. The concluding and posthumous volume of Campbell's lives of the Chancellors, containing the lives of Brougham and Lyndhurst, is an example of biography, whether due to deliberate malice or no, so full of misrepresentation and inaccuracy, to say nothing of lack of generosity and good taste in treating the life of great living contemporaries, that, as Sir Charles Wetherell wittily said, or at least re-said, the author had 'added a new sting to death.'

No form of this composition is of more abiding interest than the autobiography in which a man narrates his own history, unlocks his heart, and takes the public into confidence by laying bare the motives of his life. To know one's self was the first and last step to wisdom, according to the Greek sage—the last, indeed, for nothing is more difficult to attain than just such self-knowledge. And if a man has so much ado to understand his own heart, how much less valuable will be his diagnosis of his neighbour's. Dr Johnson thought every man's life could be best written by himself, and doubtless so it could if every man were a Dr Johnson. It is needless to say that nothing can be more difficult than to preserve the just balance between due modesty and overweening self-consciousness and self-esteem. In this form there are no better examples in the English tongue than those of Gibbon and Hume, and the opening sentence of the latter is memorable as a canon of art: 'It is difficult for a man to speak long of himself without vanity, therefore I shall be short.' It would be invidious to name modern autobiographies which reveal a complete overestimate of the writer's own abilities or importance, though our contemporary literature is by no means barren of such books, often naïve and unconscious to a degree. Autobiographies of more than ordinary interest and value are those of Lord Herbert of Cherbury, Sir Kenelm Digby, Jerome Cardan, Ellwood, Clarendon, 'Juniper' Carlyle, Thomas Boston, Franklin, Haydon, Talleyrand, O. W. Holmes, Harriet Martineau, Beranger, Miss Mitford, Mary Somerville, Hugh Miller ('*My Schools and Schoolmasters*'), Meadows Taylor, H. C. Andersen, Scott ('*Journal*'),

Leigh Hunt, Berlioz, Macready, John Stuart Mill, George Sand, Mark Pattison, Anthony Trollope, Renan in *Souvenirs d'Enfance et de Jeunesse*, Alphonse Daudet in *Trente Ans de Paris*, Sir Henry Taylor, John Ruskin in *Praterita*, and the fragment in Carlyle's *Reminiscences*, with its strange sad story of self-reproach lightened up with rare literary charm and gleams of tenderness that make it unique in English literature.

St Augustine's *Confessions* stands by itself as a revelation of the spiritual history of perhaps the greatest intellect that has ever been entirely mastered and moulded by religion. Completely different in most respects, but hardly less valuable as a confession of the strange spiritual history of a mighty intellect and a great heart, is the *Apologia* of Cardinal Newman. Sir Thomas Browne's *Religio Medici* has high value as a confession of faith, but not a little of its exceptional literary charm depends upon the pleasing egotism with which its author reveals his foibles to the reader. The *Grace Abounding* of Bunyan is a spiritual autobiography of singular intensity, in spite of itself of high value as literature. Rousseau's *Confessions* is a book of rare interest, but hardly of such precious value as its author imagined, for the ear of the modern reader never fails to detect the ring of the counterfeit that deprives it of half its charm by robbing it of reality. Goethe's *Dichtung und Wahrheit* stands quite alone as the self-told history of the artistic growth of perhaps the best-cultured intellect that the world has ever seen; but its value would be greater if, to use the author's own antithesis, we knew quite how much is truth and how much is poetry. Borrow's *Lavengro* is a book difficult to class, but is substantially an autobiography at least; and the same is equally true of De Quincey's *Confessions of an Opium Eater*, one of the strangest books in our language. Some of our greatest novels contain autobiography wrapped up more or less obscurely in them, and to the consequent reality may owe no little of their power. We know that the story of *David Copperfield* closely follows the early life of Dickens, and that George Eliot herself was just such a girl as Maggie Tulliver in *The Mill on the Floss*. There are other books about which it is doubtful how far they are fact and how far fiction, as the *Memoirs of Captain Carleton* and of *Bampfylde Moore Carew*. Defoe's *Memoirs of a Cavalier* is exactly such a book as might well have been true, and the great Chatham did no wrong to his intelligence in accepting it as actual history.

The letters of Cicero, Madame de Sevigné, Pope, Gray, Cowper, and such masters in this form, teem with invaluable autobiographical details; and indeed most modern biographies are largely made up of the letters of the subject, and thus are to a great extent autobiographic in character; while many of the larger and more important of recent biographies, as those of *General Grant* by his family, and *Charles Darwin* by his son, contain an autobiographical portion, and so belong to both divisions at once. Of Shakespeare, our greatest Englishman, there is no adequate life, and it is hardly probable that such ever will be written; of Thackeray, again, we have no life, in accordance with his own desire, though such publications as Anthony Trollope's study in the 'English Men of Letters' series, and still more the collection of his own letters published in 1887, go some way at least to supply the want. Some of the best English biographies have been already named; others are Lockhart's *Scott*; Moore's *Byron*; Morley's *Diderot* and *Rousseau*; Trevelyan's *Macaulay* and *Fox*; Sir Theodore Martin's *Life of the Prince Consort*; Carlyle's *Frederick the Great*, his *Schiller*, and his *Letters and Speeches of Oliver Cromwell*; Stopford Brooke's *Robertson* of Brighton; Chalmers, by

Hanna; Coxe's *Marlborough*; Lewes's *Goethe*; Talfourd's *Lamb*; Mrs Gilchrist's *Blake*; Mrs Gaskell's *Charlotte Brontë*; Washington Irving's *Columbus*; Sparks's *Washington*; Hayley's *Cowper*; McCrie's *Knox* and *Andrew Melville*; Lytton's life; Spedding's *Bacon*, an elaborate and not unsuccessful attempt to rehabilitate a hero; Hamerton's *Turner*; Mark Pattison's *Cusaubon*; Helps's *Cortez*, and his *Pizarro*; Froude's *Erasmus*; Forster's *Goldsmith*, *Landor*, and *Dickens*; Maurice, by his son; *Longfellow*, by his brother; Seeley's *Stein*; Dowden's *Shelley*; Cabot's *Emerson*; J. Dykes Campbell's *Coleridge*; and Lord Wolseley's *Marlborough*. Some of the more remarkable shorter biographies in English literature are Adamnan's *Life of St Columba*, More's *Henry VII.*, Cavendish's *Life of Wolsey*, Mrs Hutchinson's *Memoirs* of her husband, and *Crabbe's Life*, by his son.

Examples of scoundrelism frankly owned, as in Thackeray's *Berry Lyndon*, are Casanova's *Memoirs* and the Autobiography of Benvenuto Cellini; while examples of biographies in which the author abuses his hero, in contrast to biography as usually written, are Sir Walter Scott's and Lanfrey's lives of *Napoleon*, R. W. Griswold's *Poe*, and O'Connor's *Beaconsfield*. A remarkable example of a biography in which the reader finds almost no interest whatever save in the personality of the writer, is the life of Lord George Bentinck, by Disraeli, afterwards Lord Beaconsfield.

One other class of writings often contains miniature biographies, and at least are invaluable as materials for the biographer no less than the historian, the *Memoires pour servir*, in which French literature is so rich. Such books as Pepys' and Evelyn's *Diaries* are invaluable bits of autobiography, while they are more. Grammont's *Memoirs* cannot be overlooked by any one who wishes to understand the men and women of the Restoration; while Crabb Robinson's voluminous diaries and Senior's reports of conversations contain invaluable materials, which will give colour to biographies of nineteenth-century men and women yet unwritten, as well as add no less valuable qualifying clauses to the estimates of persons set forth in lives already in our hands. Greville's *Diaries* will ever be of great importance for the Victorian era, covering as they do a period of over forty years, and containing, with many stories and no little scandal, a few elaborate portraits.

In the French and German languages there are many excellent examples of biography. Here it may be enough to mention the names of the authors of what are among the most valuable: In France, Fléchier, Fontenelle, Voltaire, Boissy d'Anglas, Villenain, Cousin; and in Germany, Schröckh, Herder, Klein, Meissner, Heeren, Luden, Varnhagen von Ense, Barthold, Döring, Pertz, Hayn, Arneth, Otto Jahn, Chrysander, Kapp, and Droysen. Dilthey's *Schleiermacher*, Hayn's *Hegel*, and Nippold's *Rothé* may also be named. Some excellent biographies that have been translated into English are Köstlin's *Luther*, Zeller's *Strauss*, Loménie's *Beaumarchais*, Duntzer's *Goethe*, *Schiller*, and *Lessing*.

Among biographical works, some are universal, as Michand's *Biographie Universelle* (1811-28; new ed. 45 vols. 1842-65); the *English Cyclopædia*, biographical section (1856-57); *Nouvelle Biographie Générale* (46 vols. 1857-66); among older books, Bayle's *Dictionnaire Historique et Critique* (1697); Chalmers's *Biographical Dictionary* (32 vols.; new ed. 1812-17); and for our own contemporaries: Vapereau's *Dictionnaire Universel des Contemporains* (6th ed. 1892); the *Dizionario Biografico* of Gubernatis (1880); *Men of the Time* (13th ed. 1891); and *Celebrities of the Century* (1887). Of certain classes only are Vasari's *Lives of Painters, Sculptors, and Architects*; Mrs Jameson's *Memoirs of Early Italian Painters*; Cunningham's *Lives of the most Eminent British Painters*;

Doran's *Their Majesties' Servants*; Bettany's *Eminent Doctors*; Lord Campbell's *Lives of the Lord Chancellors, and Lives of the Chief-Justices*; Dean Hook's *Lives of the Archbishops of Canterbury*; Dr Smith and Dr Wace's *Dictionary of Christian Biography*; Agnes Strickland's *Lives of the Queens of England, of the Tudor Princesses, and of the Last Four Princesses of the House of Stuart*; the *Acta Sanctorum* of the Hollandists; Johnson's *Lives of the Poets* (1781); Smiles's *Lives of the Engineers*, and his *Industrial Biographies*; Grove's *Dictionary of Musicians* (1879-85); and H. A. Müller's *Biographisches Künstler-Lexicon der Gegenwart* (1882). Others again are for certain countries only, as Fuller's *Worthies of England* (1662); *Biographia Britannica* (1747; new ed., unfinished by Kippis, q.v., in 1778-83); Chambers's *Dictionary of Eminent Scotsmen* (1835); Sparks's *American Biography* (1834), and Appleton's *Cyclopædia of American Biography*, edited by J. Grant Wilson and John Fiske (6 vols. 1887-88); and our own *Dictionary of National Biography*, which commenced in 1885, and designed to extend to 50 vols., was first edited by Mr Leslie Stephen (26 vols. 1885-91), and afterwards by Mr Sidney Lee. There are special biographical collections also for Italy, France, Germany, Austria, Belgium, Denmark, and Sweden, &c.

Special groups of books that are at once biographies and critical studies are the 'English Men of Letters' series and 'Les Grands Écrivains Français.' In the former, such perfect pieces of work as Leslie Stephen's *Johnson*, Dean Church's *Spenser*, Mark Pattison's *Milton*, John Morley's *Barke*, Canon Ainger's *Lamb*, and Sidney Colvin's *Keats* were permanent gains to English literature; while the latter series opened well with Jules Simon's *Cousin*, Albert Sorel's *Montaigne*, Gaston Boissier's *Madame De Sévigné*, and E. Caro's *George Sand*. The 'American Men of Letters' series contains good studies on *Hawthorne* by J. R. Lowell, *Washington Irving* by C. D. Warner, and *Emerson* by O. W. Holmes; the 'American Statesmen,' lives of *Jefferson* by John F. Morse, and *Adams* by James T. Hosmer. A similar series is that of the 'English Worthies,' edited by Mr Andrew Lang, containing books so good as *Darwin* by Grant Allen, *Marlborough* by Mr Saintsbury, *Balcan* by Mr Gosse, and *Steele* by Austin Dobson. Other series depending largely on the biographical interest are 'The Great Musicians,' among them *Wagner* by Sir Julius Benedict, and *Wagner* by Mr Huelfer; the 'Great Artists,' with *Durer* and *Titian* by Heath, *Hogarth* by Dobson, *Turner* by Monkhouse, and *Velasquez* by Stowe; the 'Eminent Women' series, with *Maria Edgeworth* by Helen Zimmern, *Mary Lamb* by Annie Gilchrist, and the *Countess of Albany* by Vernon Lee; 'English Philosophers,' with *Bacon* by Fowler, and *J. S. Mill* by Helen Taylor; and the 'New Plutarch,' with *Columbo* by Walter Besant, *Franklin* by Beesly, *Victor Emmanuel* by Dicey, *Abraham Lincoln* by Leland, and *Haroun Alraschid* by Palmer. Somewhat similar, and indeed the earliest of such series as these, are 'Ancient Classics for English Readers,' including literary studies with a biographical setting of *Horace*, *Cicero*, *Xenophon*, *Plato*, *Aristotle*, &c.; and 'Foreign Classics for English Readers,' including similar books devoted to *Rabelais*, *Voltaire*, *Goethe*, *Pascal*, *Diderot*, &c. The 'Philosophical Classics' include monographs so masterly as *Hegel* by Edward Caird, *Berkeley* by Professor Fraser, and *Vico* by Professor Flint. The 'Twelve English Statesmen' included Freeman's *William the Conqueror* and Lord Rosebery's *Pitt*. Other series are 'Leaders of Religion,' 'Rulers of India,' 'Heroes of the Nations,' 'The Queen's Prime Ministers,' and 'Contemporary Writers.' See LETTERS.

Biology (Gr. *bios*, 'life'; *logos*, 'discourse'). This term has been occasionally abused in English popular writing, more especially in the absurd word *electro-biology*, which at one time threatened to take root in popular usage (see ANIMAL MAGNETISM), and has even by some scientific writers been confused with general physiology, or a special province of it. Yet the established and only legitimate meaning of biology is its literal one, that of the science of life—i.e. the science which seeks to classify and generalise the vast and varied multitude of phenomena presented by and peculiar to the living world. In the following outline the science and its general relations may be conveniently discussed under seven heads.

1. *Origin and Rise of Biology.*—Science being simply a systematised development of our common experience, it is with no more than that simplest knowledge of living beings possessed by the savage or the child that the future biologist sets out. These already keenly observe the forms of life around them: the sheep and goat, the dog and cat, the fowl and sparrow, the trout and salmon, are all clearly recognised and named; and similarly with plants. Classification, too, naturally arises; the birds, beasts, and fishes become more and more clearly defined; and even the residual mob of 'creeping things' discloses possibilities of orderly arrangement. Cedar and oak obtain the common name of trees, briar and bramble of bushes, balm and hyssop of herbs; but beyond this level it is not easy to pass. He is therefore 'the best botanist who knows most plants,' the greatest naturalist who can recognise the appearance and recall the names of the greatest number of living things, or at anyrate can remember most about each of them. This fundamental but as yet scarcely scientific knowledge comes to be recorded in a literature of natural history which varies indeed in accuracy and fullness, yet remains unchanged in spirit and purpose whether we open the pages of Pliny, Gesner, or Buffon. White's *Natural History of Selborne* may be taken as the classic English example of this nascent phase of biology; and its wide acceptance is not hard to understand, since at this level of simple but comprehensive interest in living beings, every one is by nature, however unconsciously, something of a biologist. But the habit of observation insensibly develops an increased perception of likenesses and differences: collections too arise; the power and need of classification develop and cultivate each other beyond the popular level, and a community of naturalists is thus insensibly formed. These divide, in the first place, into zoologists and botanists, among whom minor circles of specialists occupied with definite groups appear in turn. While this division of labour is apparent, its result is always giving us more and more definite general ideas of the groups studied, and this process of generalisation is summed up from time to time by a mind which unites the old breadth of interest with the newer depth of knowledge. Classifications are continually approximating towards completeness; our masses of knowledge respecting the plant and the animal world are at last brought together as botany and zoology, and the final advance is made through seeking to unite the generalisations of the two. Just as ostrich and swallow, shark and salmon, become united into the common logical genera of bird or fish, so inevitably do plant and animal become united into the general conception of *organism*. Their details of habit and processes of life come to be viewed in general terms of *environment* and *function*. Unity becomes more and more discerned under the manifold variety of these, and the conception of a united and general biology at last lies clear before us. It is, in fact, with the naturalist as with the chemist or mineralogist: the latter has his interest at first awakened by the variety of glistening stones, but soon finds himself eager to interpret and systematise the actual varieties of crystalline form in terms of a few simple ideal ones, with modifications in relation to particular circumstances; while the former passes from the empirical description of the experimental details of the science to the interpretation of these by reference to the properties of chemical elements and the laws of their molecular interaction and arrangement. Similarly, the naturalist passes from empirically recording his observations of living nature or the treasuring of its defunct spoils, to analyse and unify the general problems of life: and thus becomes a biologist proper. It may be well

clearly to sum this historical advance diagrammatically:

From this diagram the striking contrast, yet continuous gradation, between two such familiar classics as White's *Selborne* and Spencer's *Principles of Biology* may be clearly understood, and by tracing the steps of its correction and development (see BOTANY and ZOOLOGY), the history of scientific advance might be recorded, and even the field of each investigator marked out. Since these details will be outlined under BOTANY and ZOOLOGY, it suffices here to point out that progress has lain in continuously uniting these extremes, so that the crude empiricism which at first absorbed the more concrete students, and the vague and useless metaphysics which were wont to discredit the abstract ones, are being steadily replaced by a compact body of generalisation, along which the specialist at any point may safely ascend to the widest theories of the science, and by which the most abstract thinker may similarly return to lay clear hold of the minutest details of any order of empirical fact. Hence we can clearly understand the way in which the conception of biology was actually first formulated at the beginning of the century, independently and simultaneously by Lamarck and Treviranus (1802); the former rising from his early botanical studies and his *Histoire Naturelle des Animaux sans Vertèbres* to the elevated conceptions of his *Philosophie Zoologique*, which reached general principles as the outcome of detailed studies; while the more abstract mind of the German Treviranus occupied itself with details essentially as interpreted by the help of general principles.

The conception of biology, it will be noted, has thus come to be used with two different contents: in speaking of the principles of biology, we refer to the body of generalisations common to plants and animals; while in speaking of the science of biology, we include the entire body of botany and zoology, with all their concrete sub-sciences. Yet there is here no discord, and we may conveniently accept the definition of Charles Robin: 'Biology is the science which has for its object the study of organic beings, and for its end the knowledge of the laws of their organisation and activity.'

2. *Subordinate Provinces of Biology.*—The results of this natural history study of plants and animals, which seeks above all things to know the actual forms of life, are of course in the first place to be sought in the numerous separate articles devoted to particular animals and plants; next, in the articles devoted to separate families, natural orders, classes, and sub-kingdoms, and finally under BOTANY and ZOOLOGY: while the facts relating to their distribution upon the earth's surface, in present and in past time, are outlined under GEOGRAPHICAL DISTRIBUTION and PALEONTOLOGY respectively. Underlying this empirical view of plants and animals, yet essential to the classification which can alone give this any intelligibility or completeness, lies a detailed analysis of each of these multitudinous forms, which we call *anatomy*. This involves comparison, and *comparative anatomy* arises; but as we come to discern the marvellous unity of type which underlies all apparent differences, and as we (e.g.)

decompose all flowers into variously arranged leaf-whorls, or fancy that we can reduce all skulls to vertebrae, or again analyse the organism into organ, tissue, or cell, the conception arises of what was at first called transcendental or philosophical anatomy, but which later became known as *morphology*. This term has also been extended, and on the whole with advantage, to include not only these widest generalisations of unity in organic forms, but all the details as well, in fact all the *static* aspects of organisms as distinguished from their *dynamic* or vital ones, which we similarly group under *physiology*. In the same way the crystallographer is, as it were, the pure morphologist, but with him we can scarcely avoid including the descriptive mineralogist as well.

But while the morphologist deals primarily with the anatomical facts presented by the organism before him at a given moment, he can only fully understand the origin of these and still more their resemblances and differences by reference to its form at earlier and earlier past times: and in the endeavour to reach this fuller conception of form no longer viewed at rest, but as a result and phase of change, we constitute the sub-science of *embryology*. See ANATOMY, MORPHOLOGY, EMBRYOLOGY.

Yet our biological studies are even now not biological in the most literal sense, for the study of mere forms can take no note of the life which possessed or produced them. The morphologist's dealings are with fossil and corpse; his botanic garden is a herbarium, his appliances the scalpel and lens; whereas it is the harder task of his physiological colleague, instead of simply describing the machinery of life, to comprehend it in action. He thus of course requires an acquaintance with the results of the study of forms, but only for the sake of applying, and if possible interpreting these. In a word, his problems are no longer those of statics, but of dynamics. These dynamic or physiological problems in the first place concern the individual organism at a given time both as a whole and analysed; we study its internal and external relations—its respiration and nutrition in all cases, its sensation and movement if such there be. But the conception of phases of function at successive times necessarily also presents itself; and the more complex problems of growth and adaptation, of variation and of disease, thus arise; while when we pass from the study of the organism alone to its relations to the species, the processes of reproduction and the marvels of heredity appear for elucidation (see ENVIRONMENT, HEREDITY, PATHOLOGY, PHYSIOLOGY, REPRODUCTION, VARIATION). And in all these cases, as we shall see below, these problems may be attacked at different levels—i.e. in terms of organ, tissue, cell, or protoplasm.

3. *History of Morphology and Physiology.*—The progress of our concrete knowledge of plants and animals is respectively outlined under BOTANY and ZOOLOGY, and even from these articles it will be sufficiently obvious that these two developments are not mere isolated streams of discovery, but have a deeper than biographical interest. Our historic inquiry must now seek to fuse these two detailed chronicles of botanical and zoological advance into a broad and general sketch. This should show how the whole development of modern biology, despite its multitudes of past and present workers, and its apparently overpowering wealth and variety of detail, lies upon a few essential lines of investigation, which have been opened up by a magisterial succession of original thinkers, and simply extended and elaborated by their respective schools. For were this grasp of general principle once obtained, it is evident that we should be in

possession, not merely of an additional fragment of more or less interesting historical information, but of a well-twined and trustworthy clue which should at once guide us through the teeming maze of organic nature, and among the corresponding recesses of the vast and increasing library of biologic science.

(a) *Morphology*.—Starting then from those chaotic accumulations of fact and blunder, myth and fancy, of practical usefulness and traditional quackery, which characterise the mediæval encyclopedias of natural history, we find their inevitable criticism and replacement at length fairly undertaken in the latter half of the 17th century by the labours of John Ray and his minor contemporaries. Yet the period of general natural history was not to end for a century, for it is in Buffon's wide and brilliant survey of all that was known of animal life—the famous *Histoire Naturelle Générale*—that the ancient school found at once its highest outcome, its monument and grave. The modern period, then, essentially opens with Linnaeus, whose importance depends upon his having brought to bear upon the confused accumulations of the past the critical and analytic skill, the accuracy and descriptive power, and the classificatory resources of existing logic, which had hitherto been dragging on a merely academic or at most controversial existence, but left almost devoid of concrete or constructive applications. The importance of the order introduced by his binomial nomenclature, his establishment of the categories of species and genus, order and class, his precision of descriptive terminology and the like, can hardly be overrated; while his definite concentration for classificatory purposes upon the precise form of the organism as distinguished from its mere general appearance and mode of life, laid the basis of the future science of pure morphology. Despite the opposition of Buffon, whose thoroughly synthetic attitude and ardent enthusiasm of living nature were alike naturally repugnant to the cold analysis of the new Linnaean school, this necessarily triumphed, indeed too completely. The orderly and exhaustive catalogue of natural forms begun by Linnaeus was ardently taken up by his pupils, and handed on to his innumerable intellectual heirs; and it is still in progress, as every systematic monograph, such as those of the *Challenger* Expedition, still testifies. Each new species described means in fact a new leaf added to his *Systema Naturæ*, and the original work is thus, as it were, under continual revision and extension by a succession of sectional sub-editors. Yet, although invaluable as an index to the museum of nature, and indispensable as a catalogue for the future library of the science, the preparation of this systematic description of species gradually enslaved its labourers, and blinded them to all the other problems presented by the living beings which came under their notice. But although this disastrous tendency remains even now too common, the required deepening of the science was soon fairly begun by Jussieu, who passed from the description of external forms alone, and the artificial and provisional grouping of species by their superficial characters, to the establishment of large natural alliances upon a basis of comparative anatomy. He thus not only founded the 'natural system' in botany, but suggested to Cuvier that re-examination of the animal world upon similar lines which became his life-work. But this supplementing of superficial description by detailed anatomical and comparative research has not only given us the classic *Règne Animal* of Cuvier, but its continuation by an entire school—the comparative anatomists. Of these Meckel, Müller, and Gegenbaur in Germany, Milne-Edwards and Lacaze-Duthiers in France, Owen and Huxley in

England, will be remembered among the most historic veterans.

The next step, that of penetration below the study of organs, is due to Bichat, who analysed the body into a series of simple tissues—muscular, nervous, glandular, connective, &c., with definite structural characters. Here, then, a new movement—the histological—found its beginning, and thus under Bichat's *Anatomie Générale* we may group not only the labours of his immediate successors, but all those researches on embryonic layers and tissue structure which have of late formed an increasing proportion of recent literature.

Histology had not, however, found in the study of tissues its ultimate basis. The microscopic studies of the botanist Schleiden led him, in 1838, to the conclusion that all plant structures were built up of separate unit-masses or *cells*, a generalisation immediately extended to animal structures by Schwann, who published in the following year his famous *Microscopic Investigations on the Accordance in the Structure and Growth of Plants and Animals*, as the English translation (Sydenham Society, 1847) has it. The tissue being in this way analysed into a cell-aggregate, that elaborate and detailed study of cellular forms and structures, development and modifications, which still mainly occupies the histologist, was thus fairly begun.

Finally, the description of the essential living substance of some of the lowest animal cells by Dujardin, and the similar account of vegetable cell-substance by Von Mohl, have directed attention from the cell to the all-important protoplasm of which it is composed. Here, of course, opens a new series of investigations, in which a basis for the study of organic structure is sought in the investigation of protoplasm. No deeper analysis is possible, without passing out of morphology altogether into chemistry and physics; and we are thus warranted in regarding the preceding five great categories of morphological inquiry as exhaustive, although progress within each of these is still far from ended. It must not be forgotten, indeed, that especially since the establishment of the last two of these categories (cell and protoplasm) we have had a new light cast upon all five through the study of development, with which names like those of Von Baer, Kölliker, and others, are so imperishably associated. Thus we can now trace not only the origin and differentiation of the cell itself, but that of the tissue, the organ, and the organism, from the ovum or primeval cell. Recognising, however, this general indebtedness to the embryologist for elucidating, under the actual facts of being, their mode of *becoming*, we may still classify the labours of morphologists as being essentially continuations of the five fundamental classes above mentioned.

(b) *Physiology*.—The early physiology was a matter of very vague and often mystical interpretation of the processes of the body, as phrases like those of 'animal spirits' and 'vital spirits' still survive to show. At best it was broadly little more than a superficial account of habit and temperament, which, although corresponding to the observation of general form later inaugurated by Linnaeus, had yet little of the order and definiteness of this. The progress of anatomical research could not, however, fail to suggest that many vital processes were associated with definite organs or systems of organs, and the analytic study of physiology may be thus regarded as beginning with Harvey's memorable demonstration of the circulation of the blood. The study of the functions of each organ, viewed as a whole, long continued to form the sole problem of physiology. The illustrious Bichat was, however, no less a physiological than a morphological thinker; and in the physiological portion of his

Anatomic Générale, function was referred from the organ as a whole to the fundamental properties of its essential tissue. He thus not only deepened both morphology and physiology by a new analysis, but showed them to coincide; and in this way we come to understand how he so early clearly reached the conception of a unified science of biology.

With the advent of the cell theory, function, which had thus been referred from organ to tissue, had of course next to receive a yet deeper interpretation in terms of the constituent cells of these. Cellular physiology and pathology were clearly foreseen by Gooksir, and soon developed by Virchow and his school. Yet the interpretation of function in relation to structure, which had been successively undertaken at each deepening level, began even at this one to break down. Attention came to be directed to the nature of protoplasm, and physiology, as Foster expresses it, thus began to undergo 'a change of front.' For the physiologist has now to view the problems of function of organ, tissue and cell alike, as outcomes or accompaniments of the destructive and constructive molecular changes (*metabolism*) of its protoplasm, of the physical and chemical processes of its waste and repair, its *katabolism* and *anabolism* respectively. This ultimate school of physiology may be headed by the works of the late illustrious Claude Bernard.

It is a fact of no little significance that these two independently deepened lines of research, morphological and physiological, are accurately parallel, stage for stage; not a little remarkable that the two sub-sciences of morphology and physiology should have independently undergone a precisely similar evolution. The result of our survey may in fact be conveniently illustrated by means of a couple of similar bookcases—one for morphology, the other for physiology—the shelves of each being allotted, in descending order, to the literature of the structural and functional aspects respectively of organism, organ, tissue, cell, and protoplasm, and each shelf being headed by its initial classic. To this biological pentateuch, of morphology and physiology respectively, each set of subsequent researches must be simply regarded as commentary or appendix. For since not qualitatively distinct, the originality of these is simply of a quantitative order. And if we imagine these cases, instead of being placed side by side as in the diagram, to be situated back to back, we have a yet clearer image of the completeness of their parallelism, as well as of the way in which they have independently been filled by workers approaching from quite different sides.

MORPHOLOGICAL	ASPECT OF	PHYSIOLOGICAL
+ Linnæus	Organism.	Hippocrates +
+ Cuvier	Organ.	Harvey +
+ Bichât	Tissue.	Bichât +
+ Schwann	Cell.	Virchow +
+ Dujardin	Protoplasm.	Bernard +

(c) *Evolution*.—Where, however, it may be asked, is the position on such a scheme of the literature of

evolution? The reply of course is, that like the conception of individual development of form and function, that of racial development does not lie upon any one level, but equally below them all. The evolutionist, like the embryologist, of course considers form and function in process of continuous change, while the morphologist or physiologist views them as constant at any given moment. Hence the diagrammatic representation of our evolutionary conceptions would lie in another plane; its literature might indeed be placed on the same shelves, but behind the volumes occupying them. The history of the doctrine of evolution, like that of embryology, may therefore more conveniently be treated separately (see EMBRYOLOGY, EVOLUTION), while the subject of distribution, not being a department of pure biology at all, but rather of geology and physical geography, does not enter into the present discussion (see DISTRIBUTION).

4. *Nature and Origin of Life*.—It is by this time sufficiently clear that the biologist is solely concerned with the positive facts of living nature, and is seeking only verifiable generalisations. He accepts the relativity of all scientific knowledge, and has long been wholly freed from alchemist-like dreams of reaching any 'vital essence' or ultimate secret of life other than that of a classified and unified account of its phenomena. The history of speculation as to the ultimate nature of life may therefore be conveniently relegated to a separate article (see LIFE), in which the various attempts to define it will be found: for actual biological purposes, the life of an organism is simply the sum of its functions, internal and external; nor need any other working conception be desired, if we agree that the ideal of organic life, that of a maximum of healthy function, implies the harmonised yet progressive adaptation of function and environment. Similarly, the history of speculation as to the unknown origin of life is separately discussed (see SPONTANEOUS GENERATION); while such actual knowledge as we possess respecting the structural and functional properties and characteristics of living matter is summarised under PROTOPLASM.

5. *Place of Biology among the Sciences*.—While no special account of the logic of biology is required, save that its study demands 'observation and experiment, comparison, classification, and historic filiation'—in short, all the powers of the scientific intelligence—its relation to other studies is a matter of more serious dispute. The essential problems, briefly stated, are: (1) How far and in what way the phenomena of biology are interpretable by and related to those of chemistry and physics; (2) How physiological phenomena are related to mental ones. The reply which is offered to these questions by many biologists may be best stated in two quotations from Huxley: 'Considered apart from the phenomena of consciousness, the phenomena of life are all dependent upon the working of the same physical and chemical forces as those which are active in the rest of the world. . . . A mass of protoplasm is simply a molecular machine of great complexity, the total results of the working of which, or its vital phenomena, depend on the one hand upon its construction, and on the other upon the energy supplied to it; and to speak of "vitality" as anything but the name of a series of operations, is as if one should talk of the "horology" of a clock.' Again, 'the biological sciences are those which deal with the phenomena of living matter, and though it is customary and convenient to group apart such of these phenomena as are termed mental, and such of them as are exhibited by men in society under the heads of psychology and sociology, yet it must be allowed that no natural boundary separates the subject-matter of the latter

sciences from that of biology. Psychology is inseparably associated with physiology, and the phases of social life exhibited by animals other than man fall strictly within the province of the biologist.'

From these positions the transition is easy to the dogmatic materialism of writers who look forward to completely reducing functional and psychical processes to chemico-physical ones. But it has long been pointed out that the functional states and changes which we call physiological, and the mental states and changes which we know as psychological, have each their own definiteness and continuity. Motions are continuously traceable to antecedent motions, which may be termed their causes; nor is there any hiatus at which 'vitality' or the like can be inserted; similarly, however, changes in mentality are preceded by antecedent changes of mentality; which are equally entitled to be termed their causes. A comparison of the two streams shows indeed a definite parallelism between them; so that we constantly interpret one by the other. Feature, voice, and gesture are thus familiarly regarded as the 'expression' of psychological states, while the physician constantly ascertains the state of function by inquiring into the feelings of the patient. As, moreover, he next verifies this by a physical and chemical diagnosis, we become convinced of a complete constancy or parallelism of normal and pathological relations between chemico-physical changes, organic functions, and psychic states. The materialistic interpretation—i.e. of the latter two in terms of the first—is, however, as Comte has especially insisted, as unverifiable as would be the converse transcendental one. The links of the argument that physical changes set up the mental ones, may with equal strength be placed in precisely reverse order, to prove that psychic changes set up the physical ones. Given in fact these three orders of phenomena, physico-chemical, biological, and psychic, the labours of physiologists have done great service in establishing detailed parallelism between all these processes, yet leave the original distinctness of each category unimpaired. We can not only correlate the digestive process with normal psychic states of hunger and satisfaction, but define its physico-chemical constants, and even experimentally reproduce these in our test-tube outside the organism altogether. In a definite and very important sense, therefore, we can now say that we understand digestion in terms of chemistry and physics; but this advance of our physiological chemistry is apt to produce serious misunderstanding when it prevents the chemist from seeing that his biological colleague is not ultimately concerned with the action of the acids and ferments, in terms of which the chemical 'explanation' of digestion is expressed, but with digestion as one factor of his biological unity, the organism—as one process of its 'life'—i.e. of its adjustment of internal and external relations, a complex process with which no test-tube can present the slightest parity. Similarly, the psychic state accompanying digestion, whatever its precise physico-chemical and functional concomitants (although it is of course most interesting and desirable to define these), is only truly known by reference to the whole succession of phases or forms of mentality, which it is the problem of psychology to analyse and classify. It similarly, therefore, eludes all attempt at expression in terms of the contents of our test-tube, unless, indeed, we go so far as to endow this or its contents with specific mentality as well: this, however, would of course be an unverifiable hypothesis of transcendentalism, not a scientific materialism at all. In short, then, the physiologist is entitled to say that he knows of 'no thought without phosphorus,' but by no means that 'the brain secretes thought as the liver does bile.'

Again, since in sociology our problem is of social aggregates, the study of the individual may and does indeed furnish the most valuable data, but our ultimate sociology—i.e. our generalised and unified science—is concerned not with the individuals but with the essential drama of the race. The final *reductio ad absurdum* of the crudely materialistic position is afforded by pushing it to its logical consequence, for if, as we see many disposed to think, social phenomena fall truly within the province of the biologist, and this be but the interpretation of molecular machinery in terms of chemistry and physics, then the ultimate generalisations of sociology, the philosophy of history, would have to await elucidation by the organic chemist! It will thus be sufficiently clear that the parallelism which we are constantly establishing between all orders of phenomena, physical and biological, biological and psychological, or these and social, and which we may define as the province of a legitimate materialism, in nowise interferes with that claim to the unity and distinctness of each of these sciences, which remains as the stronghold of an equally legitimate transcendentalism.

6. *Generalisations of Biology.*—But while all these provinces of the science must be separately discussed, their results demand unification. It must not be forgotten that science, no less than music, is to be distinguished from its printed records, and even from our power of recollecting its details piecemeal. For the measure of our grasp of biology lies in our power of simultaneously orderly presentment of its whole body of essential truths before our minds, and such a breadth of synthetic vision, although demanding an exceptional effort, is becoming at least partially possible.

If we thus attempt to reach the largest possible general view of the science, we have evidently not only to unite the results of the morphological and physiological study of the organisms before us at the present moment, but to introduce the conception of past, indeed also of future time as well. This entire drama of organic existence is what we have now learned to call its *evolution*; and consequently, since this supreme generalisation has been clearly laid hold of by the students of separate sub-sciences, these have been well-nigh transformed. Their unification and detailed progress have alike made enormous advances, and we are thus rapidly approaching a unified and systematic account of organic nature.

Within the present limits only the merest outline of this synthetic view can be attempted. Starting once more at the rise of modern botany and zoology, we see the naturalists of the renaissance slowly disencumbering themselves of the literature of mere medieval traditions distorted from the classic past, which did duty for natural history, and returning to nature. We watch the rise of the systematic movement from Ray to Linnaeus, and thence trace its extending exhaustiveness, aided by new appliances like the deep-sea dredge and the microscope, new facilities like the marine station and the exploring expedition, and carried on by an ever-increasing multitude of workers. Accepting this catalogue of organisms, which, though still incomplete, is now for most purposes far more than adequate, we have next to sum up each of the successive planes of morphological and physiological research, and seize the results of the scrutiny and comparison of the form and function of organs, tissues, cells, and protoplasm of the multitude of organisms which have now been submitted to this detailed analysis. An attempt at the synthetic presentation of this must set out from the Protoplasm (q.v.), which is the 'common denominator' or 'physical basis' of life. Here we have to acquaint ourselves with the conditions of its

existence, and take note of the physiologist's enumeration of its functions as 'contractile, irritable and automatic, receptive and assimilative, metabolic and secretory, respiratory and finally reproductive' (see PROTOPLASM).

The study of the unit-mass of protoplasm or cell should next be summarised, its varied forms surveyed and classified from the simplest to the most complex and many-celled plants and animals, and these generalised into the conception of a simple 'cell-cycle,' ranging between a more or less passive and encysted spheroidal form to a less or more motile (amoeboid or elongated) one. The phases of cell form are also seen to arise as so many stages of the rhythm between growth and waste (anabolism and katabolism) into which, as we have seen above, all functions are finally summed (see CELL). The simplest organisms are separate unit-masses of protoplasm, of which the life-history essentially coincides with the cell-cycle aforesaid (see PROTOZOA). In higher but still unicellular forms, the resting or the motile phase becomes more and more permanent and specialised, and a distinctly plant or animal character thus makes its appearance. Multiplication soon becomes habitual at some one definite phase, and instead of the separation of the resultant portions to lead an independent life, we at length have their continued union. Such a union of normally resting cells gives us the multicellular plants or *Metaphytes*: that of normally amoeboid cells, the multicellular animals or *Metazoa* (q.v.). By the more passive vegetable organism the energy of the sun's rays is usually absorbed by aid of a green colouring matter (Chlorophyll, q.v.), and applied to the reduction of the carbonic acid of the atmosphere, starch and cellulose being also normal products, while their nitrogenous matter is obtained in solution as ammonia or nitrates. On the other hand, the more active animal is dependent for its nitrogenous food on proteids already directly or indirectly worked up by the agency of plants, and also for its carbonaceous on organic substances, starch, sugar, fat, &c.

Of the multicellular plant or animal only a few cells remain comparatively undifferentiated to form the reproductive elements. In these that alternate or permanent preponderance of katabolism or anabolism, which is a constitutional feature of the adult life of the great majority of living beings, usually specially asserts itself; and we have thus the development of those motile and resting forms which are henceforth respectively characteristic of the male and female 'sex' (ovum and spermatozoon). See REPRODUCTION, SEX. After a more or less distinct 'rejuvenescence' of the primeval cell-cycle, usually accompanied by that complete union with a cell of contrasted sex which we term fertilisation, the resultant cell (fertilised ovum) undergoes segmentation into an embryonic mass (see EMBRYOLOGY). From this a new adult organism gradually develops. In the animal this embryonic sphere becomes dimpled into a two-layered sac, the primeval stomach or 'gastrula'; a third intermediate layer arises, and from these three certain definite organs constantly develop. The outer furnishes the epidermis, nervous system, and sense organs; the inner layer the alimentary canal and its appended glands; and the middle one the skeletal, muscular, excretory, and reproductive systems. This unit of origin gives us a starting-point for identification of like organs in different animals, and the fertile study of *homology* thus begins. Again, this development of at first similar cell-unions into tissues and organs is readily explained as a consequence of the division of labour in the individual and in the race. The associated units have their activities restricted in one way or in another, and their energies find new outlets varying with their special

circumstances. Function establishes structure, and these gradually perfect each other; the *tissue* is thus formed, and by-and-by becomes rounded off or combined with other tissues into a definite mechanism, the *organ*, while these may form a still larger unit, the *system*. It is therefore the development and complexity of this physiological progress of division of labour which determines the special and general form of the organism. We thus see how the results of pure morphology (anatomy without regard to physiology) acquire a rational explanation by reference to the physiological processes which shape organic forms. With increasing complexity of structure we have necessarily an increasing simplicity of function, for the many processes at first crowded into a single cell become, so to speak, sorted out into the different organs. Residual traces of all these protoplasmic properties must, however, remain in varying measure in even the most specialised of living cells, hence the possibility of functional change is never closed, since use, disuse, or changing circumstances may set up a renewed increment of any one or a continued decrement of any other of these minor processes, however apparently suppressed. Here in this latent potency of change we have in short the rationale not only of the cell-cycle with which we set out, but the explanation of the otherwise mysterious phenomena of reversion and progression—in fact, of the occurrence of all variations, normal or pathological alike. See PHYSIOLOGY, PATHOLOGY, VARIATION.

It is clear that this specialisation of organs involves their dependence upon each other, and that if one suffer or develop, this must affect all its partners in the general life. Hence we obtain 'correlated variations,' and interpret the various symptoms of a given disease. Progress as regards organs is thus twofold—(1) in continued development and increased division of labour of the parts (differentiation); (2) in increasing correlation of the parts to each other and in subordination to the whole (integration). And when we note that any higher integration depends upon a preceding new differentiation, which of course disturbs the existing equilibrium of the whole, we are in a position at once to comprehend the beginnings of disease, and to realise that the traditional pessimistic interpretation of this admits of important modification.

A strict classification of the organs is rendered difficult by the varied ways in which different organisms have solved the problems of adaptation: a general correspondence to those essential properties of protoplasm which we noted at the outset is of course observable, since the frog has no functions which were not foreshadowed in the amoeba. The older physiologists, however, clearly pointed out that the primary classification is that which separates the reproductive or species-regarding functions from the remaining individual ones: while the latter are again divisible according as they are concerned with the internal problems of the organism—i.e. with nutrition (also circulation, mechanical support, &c.) or with the external problems of relation to the environment (sensory, nervous, muscular). These fundamental contrasts between reproduction and individual development, and between the vegetative and the animal functions, are in fact the largest physiological features of organic nature, and admit of fruitful application (see VARIATION) to interpret the endless details of plant and animal form and life.

Returning to these, which we are now in a position to view as an ordered whole, we find that (a) the successive appearance of related types upon the globe broadly (and sometimes even minutely) corresponds to (b) the order of increasing complexity established on purely anatomical grounds, while

the embryologist (c) finds that the development of the individual from its unicellular simplicity to adult complexity repeats the same essential succession of phases. This threefold coincidence next demands explanation, and the 'theory of descent' from a flora and fauna of increasingly simpler character in the past necessarily makes its appearance; nor has any other scientific explanation been suggested. But this modification during descent next demands explanation; a problem of supreme difficulty which has had many attempted answers.

From all these repeated attempts to discern the principle of organic progress, the naturalist has been learning to change the static or anatomical view of living nature for the dynamic and physiological one—in other words, to rise from the analysis of the individual as a dead specimen to the conception of the species as a living whole. The commanding superiority and wide scientific influence of Darwin among naturalists are of course popularly, though groundlessly, associated with the origin instead of the final popularisation of the conception of descent; while even by scientific men they are frequently assumed to be essentially associated with his particular hypothesis of natural selection as the rationale of progressive modification; yet his biological influence and example primarily depend on his having fairly established in practice this great transition from the pursuit of dispersive specialisms towards attempting a general view and explanation of organic nature. Since his time, our knowledge of the plant can no longer be grouped round the dried herbarium specimen of it, as had been the case since Linnaeus' day. It has become again for us a living being, not only breathing, and growing in the sun, but moving, digesting, sensitive, often in a measure hardly second in its fullness to that of animal life—in a word, the dryad of old poetry has been recalled to life by modern science. The individual, too, has wide relations, here it may be to other plants, here to insects, there to birds and beasts; the entomologist must leave his museum, and the botanist his herbarium, to work out in the garden together the steps by which flower and plant have wrought out each other's form and destiny; they have soon to call in other specialists to their aid; and the world thus comes to be understood as a vast and complex web of life, and its many forms as related to each other by innumerable complex ties. Thus the farmer's cat influences his clover crop, or the distribution of a particular insect determines alike the civilisation and the scenery of vast regions of Central Africa. In this way the unit-problem of the science has become no longer the description of the isolated specimens of its index collections, but the history of the entire species in its living relations, actual and historic.

Since the doctrine of natural selection, which is the more immediate contribution of Darwin and his school to the theory of evolution, will be found summarised under DARWINIAN THEORY, and discussed under EVOLUTION, it suffices here to point out that, despite its wide applicability and indisputable services, its finality is again becoming disputed by various naturalists on different grounds (see EVOLUTION, VARIATION). On one side the older explanations, in terms of use and disuse, environment, &c., are being revived; while on another, it is being attempted to replace the received doctrine of indefinite variation, with progress by means of struggle for existence among individuals, by the conception of definite variation (even pathological), with progress essentially in the measure of the subordination of individual struggle and development to species-maintaining ends, reproductive, domestic, or associative. Without entering into details, it is evident that such a

restatement of the theory of the evolution of living beings—in terms no longer primarily of strength and competition, of hunger and battle, but of love and co-operation, of sacrifice and pain—would involve, no less fully than has the doctrine of struggle for existence, a deepened reinterpretation of plant and animal life, and would similarly extend into other fields than those of pure biology.

7. *Conclusion—Biology and Practical Life.*—While biology as a science finds its source and justification in the natural impulse to contemplate, and reasonable desire to comprehend the world and our place in it, its action and reaction with practical life requires brief consideration. Our knowledge of animals, like the child's, obviously arises with their chase; and that of the aspects and properties of plants, wholesome and poisonous, perhaps even medicinal, with the hungry search for roots and berries. The evolution through higher social states finds its reflection in widening zoological and botanical folklore, and the developed agricultural conditions of civilised life not only admit of the increasing and systematising of our knowledge, but even at length contribute valuable conceptions, like that of selective breeding, of which Darwin has made such especial use. The recent contributions of biology to the arts of life have been of course primarily associated with the advance of medical treatment; hence the popular and even medical conception of the botanist is still based upon the traditional one of the herboriser in quest of specific remedies. The increase of food-supply, through pisciculture and breeding, and through the destruction of the enemies of useful species, is an application of more recent but widening growth; in fact those applications of our knowledge of cryptogamic pests which have especially culminated in the labours of Lister and Pasteur (see GERM THEORY), at present furnish the stock illustration of the applicabilities of pure biology. New ideas are also germinating; thus speculation is busy—e.g. with schemes of artificial human selection; while rapid progress is being made in the transition from detailed medicine to wholesale hygiene—i.e. beyond the mere application of specific remedies to morbid individual variations, and towards a progressive and harmonious reorganisation of the functions and environments which are afforded by the human hive or city to its individuals. For the task of biology applied as hygiene should not only be to subdue the tendencies to morbid variations, but to determine that maximum of optimum life-cycles, which is the biologist's and hygienist's concrete rendering of the greatest happiness of the greatest number. And as the twin scientific motives of childlike curiosity, with its analytic pursuits, and of maturer contemplation, with its synthetic aims, become balanced by the corresponding practical ones of the arts and their application to the general humanist problem just outlined, our biological science and art may be fairly expected to react more and more fully in their associated yet alternate progress.

This hope is indeed confirmed by the whole past history of the science; with a glance at which in its most general aspect the present article may fitly conclude. At the very outset (§§ 1, 3) we saw that biology is no mere isolated stream of fortuitous discovery; next (§ 5), that it is no mere separate discipline which can be exhaustively pursued apart from other sciences; and—now (§ 7), that it has arisen from, and constantly returns to, ordinary life and practice. In tracing the progress of biology, we are simply following the reflection of the changing lights cast upon the organic world by each prevailing mode of general thought and social life. In a word, the evolution of biology forms part of the general social evolution; the science is no

completed body of truth, but merely such portion of it as our stage of social progress enables us to see. Else the rise of science from art would be little more than an almost prehistoric process, instead of being still and continually going on. Innumerable instances, large and small, might be given of this; thus, the classificatory doctrine of the 'échelle des êtres' (see ZOOLOGY) due to the naturalist Bonnet, is far more than a mere detail of the biographical history of zoology; for the conception of an unbroken series of beings ascending in regular gradation from the lowest up to the highest is obviously the projection upon nature of that established ecclesiastical and social hierarchy in which the good abbé's mind was formed. Again, taking a larger instance, the substitution of Darwin for Paley as the chief interpreter of the order of nature is currently regarded as the displacement of an anthropomorphic view by a purely scientific one: a little reflection, however, will show that what has actually happened has been merely the replacement of the anthropomorphism of the 18th century by that of the 19th. For the place vacated by Paley's theological and metaphysical explanation has simply been occupied by that suggested to Darwin and Wallace by Malthus in terms of the prevalent severity of industrial competition, and those phenomena of struggle for existence which the light of contemporary economic theory has enabled us to discern, have thus come to be temporarily exalted into a complete explanation of organic progress.

Finally, the division of labour having become fully established in industrial practice, and recognised in economic theory by Adam Smith, it was frankly borrowed for biological application by Milne-Edwards, almost a couple of generations later, with fruitful results. This industrial development has indeed not only given us our present clear conception of separate organic functions, where an earlier school could see only their general resultant as 'temperament,' but it has also determined the prevalent intensity of scientific specialism within artificially restricted fields. Hence too, the extreme specialist's not infrequent loss, if not indeed denial, of definite responsibility to the science as a whole, and still more to that larger progress of which it forms a part, is simply the equivalent of that loss of conscious relation both to the special task and to its general bearings, from which at present the labourer also so frequently suffers. But as we progress with the synthetic reorganisation and practical application of the science, we may anticipate the recovery of both.

The manifold importance of biology in education is seen not only in its practical applications in the arts and in the study of medicine, but as a potent agency of culture, and as preliminary to psychological and social studies. See BOTANY.

Literature.—See, beside articles mentioned above, LAMARCK, SPENCER, WEISMANN, &c.; also Comte, *Philosophie Politique*; Robin, *La Philos. Pos.*; Laffitte, *Revue Occidentale*, i.; Spencer, *Principles of Biology* (1866); Haeckel, *Generelle Morphologie* (1866); Huxley, *Anatomy of Invertebrate Animals* (1878); text-books by J. R. A. Davis (1888), R. J. H. Gibson (1889), T. J. Parker (1891), H. G. Wells (1893); J. Arthur Thomson, *The Science of Life: an Outline of the History of Biology* (1899); Alfred Earl, *The Living Organism* (1899).

Bion, second of the three Greek bucolic poets, was a native of Smyrna, but settled in Sicily, where he is said to have been poisoned by a jealous rival. He imitated his earlier contemporary Theocritus; Moschus calls himself his pupil. Little of his work has survived save his 'Lament for Adonis.' His works are usually edited with those of Theocritus (q.v.); Mr Lang gave us a good prose translation of the three (1889).—**BION OF BORYSTHENES** flourished about 280 B.C. At first a Scythian slave,

he studied philosophy at Athens, and afterwards lived at the court of Antigonos Gonatas.

Bioplasm is a word introduced by Professor Beale for the germinal matter of living beings—i.e. living protoplasm. See PROTOPLASM.

Biörnson. See BJORNSSON.

Biot, JEAN BAPTISTE, a distinguished French physicist and astronomer, born at Paris, April 21, 1774. He entered the artillery, but forsook the service for science, and in 1800 became professor of Physics in the Collège de France. Along with Arago (q.v.), he was (1806) sent to Spain to carry out the measuring of a degree of the meridian, and in 1817 he visited England, and went as far north as the Shetland Islands, in order to make observations along the line of the British arc of meridian. His most valuable contributions to science are on the polarisation of light, for which he received the Rumford gold medal in 1840; his researches into ancient astronomy are also very valuable. Among the latter may be mentioned his *Recherches sur l'Ancienne Astronomie Chinoise* (1840) and *Études sur l'Astronomie Indienne* (1862). His works on physics are still esteemed; the 3d ed. of his *Traité Élémentaire d'Astronomie Physique* (5 vols. 1841-57) was translated into English. In 1849 Biot was made a Commander of the Legion of Honour; he was also a member of the French Academy, and of most of the learned societies in Europe. He died at Paris, February 3, 1862.—His son, EDOUARD CONSTANT, a distinguished Chinese scholar, was born at Paris, July 2, 1803. He was at first a railway engineer; but his health failing, he retired from the public service, and devoted his leisure to the study of Chinese and the history of the social organisation of the Celestial empire. He was elected a member of the Academy in 1847, and died March 12, 1850. He wrote a *Dictionnaire de l'Empire Chinois* (1842), and a multitude of *Mémoires* on Chinese subjects.

Biotite. See MICA.

Biped (Lat., 'two-footed'), a descriptive term, sometimes applied to man, but more frequently to birds. It may be used in two ways—(a) in reference to habit only (physiological), when animals use only their two hind-limbs for moving along the ground—e.g. man, kangaroo, bird; (b) in reference to anatomy (morphology), when the typical number of four limbs is reduced to two. Thus among mammals the order of whales (Cetacea) is marked by the absence of hind-limbs; among birds the fore-limbs are considerably reduced in the running birds of the ostrich sub-class, and especially in the New Zealand Kiwi (*Apteryx*); among reptiles, some serpents (e.g. Pythons) retain traces of hind-legs, while all the others have lost both pairs, and a few lizards have either only hind-feet (*Pseudopus*, *Ophiodes*), or only fore-feet (*Chirotes*); among amphibians, a few (e.g. *Siren*) have only fore-feet; and the same is true of numerous fishes (e.g. among Siluridae), and especially of those which live to a large extent in mud.

Bipinnaria, the technical name of a starfish larva. It is a curiously-shaped free-swimming form, with two ciliated bands, and with a tendency to develop long stilt-like arms or processes. It does not directly turn into the adult, but is only its 'nurse.' The adult is formed within the bipinnaria. See ECHINODERMS, STARFISH.

Biquadratic. See EQUATIONS.

Bir, a town of from 1800 to 2000 houses, of Asiatic Turkey, on the east bank of the Enphrates, 80 miles NE. of Aleppo.—The Arabic *Bir*, which signifies 'well,' is the Hebrew *Beer*.

Birbhum, a district in the Bardwan division of Bengal, with an area of 1756 sq. m. Rice is

the chief crop. Birchum is one of the greatest copper-fields of the world, though practically untapped as yet.

Birch (*Betula*), a genus of Betulaceæ, which contains only the two genera, Birch and Alder (q.v.), and is frequently reckoned as a sub-order of Amentiferae (q.v.). The twenty-five species of birch are all trees or shrubs, natives of northern, temperate, and arctic regions.—The Common Birch (*B. alba*) has small, long-stalked, somewhat triangular doubly serrated leaves. It is a very beautiful and rapid growing, but unfortunately short-lived forest-tree, of the colder palaearctic region, which in favourable situations attains a height of 50 to 60 feet, with a diameter of 1 to 1½ feet, but diminishes in size towards its arctic or alpine limit, at last becoming a mere bush. It is the last tree to disappear as we proceed northwards or upwards, and hence the most important tree of Northern Russia, &c., where it often forms whole woods. No other tree exists in Greenland; and according to old popular belief, it was the only tree that grew in paradise. The bark is smooth and silvery white, and its outermost layers are thrown off as the tree advances in age. The smaller branches are very slender and flexible, and in a particularly graceful variety called the Weeping Birch (*B. A. pendula* of some botanists), they are still more slender, elongated, and pendulous. The bark and leaves of the birch are, in some northern countries, used medicinally in cases of fever and eruptions. They are also used for dyeing

Flowering Branch of the Common Birch.

yellow. The bark is sometimes used for tanning, and for steeping nets, sails, and cordage (see BARK FOR TANNING). It is in some countries made into shoes, hats, drinking-cups, &c., and is even twisted into a coarse kind of ropes, and is the material of which the North American Indians made their light canoes. It is remarkable for its durability, which even exceeds that of the wood itself. In many parts of the north of Europe it is used instead of slates or shingles by the peasantry; and in Russia—the outer or white layers being subjected to distillation—there is obtained a reddish empyreumatic oil called Birch Oil, of which a somewhat tarry form, the so-called *degutt* or *degget*, is employed in the preparation of Russia leather. Dried, ground, and mixed with meal, birch bark is used in Norway for feeding swine; and in times of scarcity has even served for human food. The wood is white, firm, and tough, and is employed by turners, wheelwrights, and coopers, who use it in the manufacture of barrels for fish. Much of it is made into charcoal for forges. The twigs are in general use for besoms, and for the 'birch' used in flogging naughty boys. On account of its fragrant smoke, birch brushwood is much em-

ployed in smoking hams, herrings, &c. In many countries the sap is not only used as a beverage in a fresh state, but is converted by fermentation into a kind of wine. The White Birch of North America (*B. populifolia*) very nearly resembles the common birch, and is also extensively used. The Black Birch of the same country, but of more southern range (*B. nigra*), also sometimes called Red Birch, produces very hard and valuable timber. But the name Black Birch is also given to another species sometimes called the Sweet Cherry Birch (*B. lenta*), itself a large and valuable timber-tree. Its leaves make an agreeable tea. The Yellow Birch of Nova Scotia, Maine, &c. (*B. excelsa*) is a large tree with leaves 3½ inches long; its timber is used in shipbuilding. The bark of the Paper Birch (*B. papyracea*) is capable of division into very thin sheets, which have been used as a substitute for paper. It is used by the Indians and French Canadians for canoes, boxes, buckets, baskets, &c. Large plates of it are curiously stitched together with the fibrous roots of the White Spruce, and coated with the resin of the Balm of Gilead Fir. *B. occidentalis* is an interesting species found on the Pacific slope. The mountainous districts of India also produce several useful species. Thin, delicate plates of the bark of *B. bhajputtra* are used for lining the tubes of hookahs, and were formerly used as paper. *B. acuminata*, a native of Nepal, has strong and durable wood.—The Dwarf Birch (*B. nana*) is a mere bushy shrub, seldom more than 2 or 3 feet high, and generally much less. It has orbicular crenate leaves. It is a native of the whole of the most northern regions of the globe, and is found as far south as the Highlands of Scotland. It is interesting because of its uses to the Laplanders and other inhabitants of very northern regions, to whom it supplies their chief fuel, and the material with which they stuff their beds. Its seeds are the food of the ptarmigan, on which the Laplanders in a considerable degree depend. A similar shrubby species (*B. antarctica*) occurs in Tierra del Fuego.

Birch. SAMUEL, Egyptologist, was born in London, 3d November 1813, the son of a city clergyman. Educated at Merchant Taylors', in 1834 he entered the public service under the Commissioners of Public Records; and in 1836 he became assistant in the antiquities department of the British Museum. In this capacity, Birch acquired an extensive acquaintance with archaeology in all its branches. He studied not only Greek and Roman antiquities, including numismatics, but applied himself with untiring zeal to Egyptian hieroglyphics. In process of time, he so distinguished himself in this difficult branch of learning, that Baron Bunsen availed himself of Birch's knowledge in the philological portion of *Egypt's Place in Universal History*, the last volume of which, after Bunsen's death, was admirably edited by Birch. In 1844 he was appointed assistant-keeper of antiquities; in 1861, keeper of the Egyptian and Oriental antiquities. He received an honorary LL.D. from St Andrews in 1862, and from Cambridge in 1874, in which year he was president of the London Congress of Orientalists. He was a corresponding member of several academies, and was a contributor to various learned journals, to the *English Encyclopædia*, and to *Chambers's Encyclopædia*. Besides three works connected with his Chinese studies, he was author of *Ancient History from the Monuments of Egypt* (1875), *Egyptian Texts* (1877), &c. He died in London 27th December 1885.

Birch. THOMAS, D.D., an industrious historical writer, born at Clerkenwell in 1703, was the son of

a Quaker, but in 1730 took Anglican orders, and received half a dozen preferments in the course of the next thirty years. He was killed by a fall from his horse in the Hampstead Road, 9th January 1766. He was author or compiler of *Lives of Boyle, Tillotson, Queen Elizabeth, Prince Henry, &c.*

Birch-Pfeiffer, CHARLOTTE, a German actress and dramatist, was born at Stuttgart in the year 1800. She made her début at Munich at the age of thirteen, and afterwards played with great success at Berlin, Vienna, and Hamburg. In 1825 she married Dr Christian Birch of Copenhagen, and in 1837, after performing at Petersburg, Pesth, Amsterdam, and other places, she undertook the management of the theatre at Zurich. At a later period, she acquired even greater renown as a writer for the stage than as an actress. In 1843 she made an engagement with the theatre-royal at Berlin, in which town she died, August 24, 1868. Madame Birch-Pfeiffer's plays attain no very high standard, but are still popular with German audiences. A complete edition of her dramatic works has been published in 23 vols. (Leip. 1863-80), and of her novels and tales in 3 vols. (1863-65).—Her daughter is the well-known novelist Wilhelmine von Hillern, whose daughter also is already a successful novelist.

Bird. Birds are in some ways the highest of the vertebrate animals. They represent the climax of that passage from water to land which the backbone series illustrates. Their skeleton is more modified from the general type than that of mammals; their arrangements for locomotion, breathing, and nutrition are certainly not less perfect; their body temperature, higher than that of any other animals, is an index to the intense activity of their general life; their habitual and adaptive intelligence is familiarly great, while in range of emotion and sense impressions they must be allowed the palm. It is, in fact, only when we emphasise the development of the nervous system and the closeness of connection between mother and offspring, that the mammals are seen to have a right to their pre-eminence over birds. Birds and mammals represent two divergent lines of progress, and stand in no close connection, but the affinities between birds and reptiles are sufficiently marked to warrant their being included in a common class (Sauropsida), in contrast to the amphibians and fishes (Ichthyopsida) on the one hand, and Mammalia on the other. Among the numerous points of difference which separate birds from their nearest relations the reptiles, and from mammals, the following may be noticed:

	Reptiles.	Birds.	Mammals.
Covering.....	Scales or scutes.	Feathers.	Hair.
Number of fingers.....	Always more than three.	At most three.	Five or fewer.
" skull condyles..	One.	One.	Two.
" aortic arches...	At least two.	One, right.	One, left.
Diaphragm.....	Only incipient.	Only incipient.	Complete.

Parturition.....	Ovi- or viviparous.	Oviparous.	Except two, viviparous.

But those contrasts are only a few of the less technical selected from Professor Huxley's masterly comparison of the three classes. To appreciate the full extent of the resemblances and differences between birds and reptiles, and the contrast between both and mammals, the reader must consult Huxley's *Anatomy of Vertebrate Animals*.

History of Study of Birds.—As birds are even to a careless eye most markedly separated from all other animals, there has rarely been any difficulty about the limits of the class. Aristotle (300 B.C.) defined them as feathered flying bipeds which lay eggs, and catalogued a goodly list, divided into three great orders, with the ostrich and a few others in separate subdivisions. He did not include bats in his list. For eighteen centuries no real progress was made with the study of birds. They were not of course lost sight of, but were abundantly discussed, now from a semi-religious, now from a practical point of view, yet it was not till the outburst of naturalist enthusiasm in the 16th century that they became again objects of scientific study. It is indeed curious, after a lapse of 1800 years, to find William Turner describing the birds enumerated in the catalogues of Aristotle and Pliny. Of the school known as Encyclopædists, Belon (1555) devoted himself especially to the study of birds, and made the great step of comparing the skeletons of bird and of man bone for bone. In the subsequent classificatory enthusiasm inaugurated by John Ray, and perfected by Linnaeus, birds came in for a full share of attention, but the numerous naturalists who, towards the end of the 18th century, tried to put the birds in order, have left in their discrepant systems a record of the difficulty of a task which is still acknowledged to be bewildering. They fixed their attention mainly either on superficial characters, such as bills and feathering, or on general facts of habit, such as running and swimming. In other directions, however, progress was made: John Hunter (1728-93)

and Vieq d'Azyr (1748-94) made important investigations on the skeleton and musculature of birds, while Caspar Friedrich Wolff, turning in 1764 to the problem of chick-development, the study of which had begun in Greece more than nineteen centuries before, laid the foundations of modern embryology. Then followed the Cuvierian school of anatomists, and to the works of the master himself, and of his numerous disciples, most of our present knowledge of bird anatomy is due. Numerous attempts at classification were again made, but even yet no one detailed system is generally adopted. General ornithology has been greatly enriched by the monographic, and in some cases stupendous labours of enthusiasts like Naumann, Thienemann, Audubon, Gray, Wilson, Gould, Selater, &c. In recent years we are mainly indebted to Owen and Marsh for knowledge of fossil forms; to W. K. Parker for embryology; to Selater, Wallace, Newton, and others for distribution; and for a scientific classification to Professor Huxley.

Structure.—(a) With the general form of birds every one is familiar; the frequent length of the neck, the inconspicuousness of the fore-limbs when at rest, the length of the hind-limbs, the reduction of the tail, the boat-like form of the main body, the smooth gracefulness of the contour curves are at once evident. (b) As to the appendages, the modification of the fore-limbs for flight in the great majority of birds is the most marked characteristic. While the flying reptile, Pterodactyl, had a membrane stretched on the much elongated little finger, and the bats have their skin spread out between their elongated four fingers, the bird has never more than three fingers, and these much reduced. The stroke, as every one knows, is effected not by a stretched skin, but by the strong stiff feathers. The most marked general feature in the legs is the elongation and fusion of the bones just below the ankle (metatarsals).

The toes are never more than four, except in abnormalities. The spur of the cock is thought by some to represent a toe. (*c*) The integument differs markedly from that of other animals in

Fig. 1.

a, fore-limb of pigeon; b, fore-limb of bat; c, fore-limb of pteromethyl.

being clad with feathers. These are skin structures generally comparable to scales or hairs. Their development will be discussed separately (see FEATHER), but it may be noted that in consequence of certain conditions of skin growth, numerous elevations are formed both of the outer and inner layers. These growing outwards, and at the same time fixed below in little pits, become to a large extent horny, and are split up in various ways to form feathers. The outermost sheath becomes a horny case which falls off as the feather grows; the feather proper is due to a horny modification of the inner stratum of the outer skin or epidermis; the inner skin (*dermis*) forms a nutritive base which, with its blood-vessels, keeps the young feather alive, but becoming subsequently reduced, leaves the perfect structure virtually dead. They do not usually occur all over the body, but in definite feather-tracts, as can be readily seen by plucking small or young birds. Some birds, however, like the penguin are really feathered all over. Three distinct kinds of feathers are at once distinguishable—(*a*) the small hair-like downy rudimentary *filoplumes*; (*b*) the numerous smaller contour or covering *plumes*; and (*c*) the large strong quill-feathers or *pennae* on wings and tail. The ordinary feather consists of a quill at the base of a shaft up the centre, and of the vane borne on the sides of the shaft. The vane consists of parallel barbs, which are linked together by small barbules. The base of the quill bears a miniature feather or after-shaft, which in a few cases becomes as large as the main feather. On the bare legs of many birds the feathers are replaced by horny scales, and the horny structures forming the beak and terminating the toes are very familiar. Skin glands, so abundant in mammals and elsewhere, are here absent; but at the very end of the tail there is a two-lobed oily preen-gland, the secretion of which is used by the bird for anointing and waterproofing its feathers. Curious skin structures, such as combs and wattles, are often developed.

Skeleton.—The most important peculiarities of the bird skeleton are the modifications of forelimbs and girdle in association with flight, the abundant air-cavities (only absent apparently in the kiwi or apteryx), which make the bones so light and spongy, and the tendency the bones have to fuse together. (*a*) The *backbone* is very different from that of other animals. The several backbone bodies (vertebrae) have a very complex shape, and are not to be mistaken for those of any other vertebrate. While the neck of mammals almost

always consists of seven vertebrae, that of birds includes a larger and variable number, amounting to over a score in the swan. Unlike the very movable neck, the dorsal region tends to become more or less rigid, especially behind, where a large number of vertebrae enter into immovable connection with the hip-girdle. Behind this there are a few caudal vertebrae which are again mobile, and end in a compound ploughshare-bone which bears the great steering feathers of the tail. The most anterior ribs are fused to the vertebrae; then follow a few (two in the fowl) which are free, but do not reach

Fig. 2.—Skeleton of Fowl (exhibited in section):

the breastbone; the next set meet, at an angle, upward processes from the breastbone, with which they are thus indirectly connected. The last ribs are again free. Almost all the ribs bear backward directed (uncinate) processes which overlap the rib behind. These also occur in crocodiles. (*b*) The *skull* of course corresponds in general structure to that of other vertebrates, but is distinguished by the early fusion of the component bones, so that the contours are no longer visible, by the prolongation of the front bones to bear the beak, by the absence of teeth, by the large sockets for the eyes separated from one another only by a thin (sometimes perforated) partition, and by the marked lightness of the bones. There is only one ball (condyle) which turns on the cup of the body of the first (atlas) vertebra, the bone (quadrate) on which the lower jaw works is movable, the portion of the skull lying in front of the eye-sockets is slightly movable on the portion protecting the brain, the tongue-bone (*hyoid*) is very well developed. It is on the relations of certain bones of the skull that Huxley bases his anatomical classification. (*c*) The *limbs*.—The *shoulder-girdle* consists (1) of a long bone running backwards (the shoulder-blade or *scapula*), (2) of a shorter bone running from the shoulder down to the breastbone (the

coracoid, only a process of the scapula in mammals), and (3) of a slender collar-bone (*clavicle*) which extends from the shoulder to meet its fellow in front of the breast, forming with the broad uniting plate the familiar 'merrythought.' The *breastbone* or sternum forms the base of attachment for the great muscles which work the wings, it is concave

Fig. 3.—Breastbone and Shoulder-girdle of Falcon:

a, clavicle; b, scapula; c, coracoid; d, keel of sternum; e, ribs.

internally, and in most birds bears a prominent ridge or keel on the middle line in front. As this ridge serves for the fixing of the flight muscles, it is largest in the birds which use their wings most, and absent in those, such as the ostrich family, which use them either not at all, or very little. The flying keeled birds (*Carinatae*) are in the immense majority; the running birds, with flat raft-like sternum (*Ratitae*), are few. Even among birds of flight, comparative disuse of wings may be associated with a slight development of the keel. In the New Zealand parrot (*Strigops*), and a few more, the keel is very rudimentary. The *arm* consists as usual of a strong upper bone or *humerus*, working in the socket formed by scapula and coracoid, of two bones forming the forearm, the *radius* and the stronger *ulna*, of a single pair of wrist-bones, and of three fingers. The three bones corresponding to the palm of the hand (the *metacarpals*) are fused together, the thumb has two, the first finger three, the second finger one or two joints. The terminal joints of the thumb and first finger are sometimes clawed. In the kiwi and cassowary there is only one complete finger, apparently the second. The feathers attached to the hand are usually called primaries, and those borne on the ulna, secondaries. The *hip-girdle* is very long, and its most important part consists of two dorsal bones (*ilia*) which are fused to a large number of posterior backbone bodies. A second

Fig. 4.—Hip-girdle of Fowl:

a, ilium; b, ischium; c, pubis; d, socket.

portion (the *ischium*) extends backwards on either side, nearly parallel to the hind part of the ilium with which it is firmly fused. The third part (or *pubis*) also runs backwards from the socket of the thigh, and is a slender bone nearly parallel to the former. Only in the ostrich (*Struthio*) do the two pubes really unite; but in other birds they are bound together by fibrous tissue. In the American ostrich (*Rhea*) the two ischia are united ventrally. The socket formed by the union of the three portions of the hip-girdle is incompletely bony (perforate), as is also the case in one of the lowest mammals, the porcupine ant-eater, or *Echidna*. The thigh (*femur*) is a short stout bone. It is followed by the two bones of the lower leg, one of which (the *fibula*) is always imperfect and fused to the strong *tibia*. The knee is generally protected by

a knee-pan or *patella*. The ankle is peculiar in this, that the upper portion unites in the adult bird with the lower end of the tibia, which is therefore known as the *tibio-tarsus*, while the lower portion unites with three of the bones corresponding to the sole of the foot (metatarsals), which are therefore known as the *tarsometatarsals*. In the adult there are thus no distinct ankle bones or tarsals, these having become fused to the tibia above, and to three of the metatarsals below. Birds have only four toes, and the metatarsals of the second, third, and fourth are fused together. The metatarsal of the great toe remains separate, but in many birds this digit is wholly undeveloped. The

Fig. 5.—Feet of various Birds:

a, swift; b, stilt; c, black stork; d, wryneck; e, falcon; f, raven; g, kingfisher; h, pelican; i, grebe; k, coot; l, smew-duck.

ostrich has only two toes. In most cases the number of joints in the toes increases by one, from two in the first to five in the fourth toe. The toes vary considerably in direction according to the way they are used. A bony spur ensheathed with horn is sometimes developed (as in the cock) in connection with the metatarsus.

Muscular System.—The most important muscles of the bird are those which work the wings. These lie on the breastbone, which forms their base of attachment. The great pectoral muscle which forms the greater part of the breast *depresses* the wing; a second smaller and deeper muscle, covered by the former, is continued into a long tendon which passes through a hole at the shoulder-joint, is inserted on the back of the upper arm, and *raises* the wing; a third much smaller breast muscle also assists in elevating the wing. It is well known that birds may remain firmly perched when asleep. This is effected by an automatic muscular arrangement. The tendon of a muscle which bends the toes passes up to the hip over the knee-joint, so that when the knee is bent in perching, the tendon is stretched, and the toes are kept firmly fastened. There is a strong development of muscles in association with the gizzard or stomach-mill.

Nervous System.—The brain of birds is markedly more developed than that of reptiles, the parts no longer lie almost on one plane, and the organ occupies the whole of the spacious skull-case. The convolutions characteristic of the fore brain of mammals are not yet developed. The 'twain brain (*optic thalami*) is quite hidden, the mid brain (*optic lobes*) is thrust to either side, the hind brain

(*cerebellum*) exhibits cross grooves. There are twelve pairs of nerves given off as usual from the brain. The spinal cord exhibits in the hip region a conspicuous enlargement due to the divergence of its two sides. The *sense-organs*.—In association with their manifold experience, birds have well developed sense-organs.

This is especially true of the eyes. They are large and powerful, and can be rapidly accommodated to different distances. They differ only in minor points from those of any vertebrate. The form is far from spherical, the front portion being protruded, and to a certain extent constricted off from the ball behind. A special ring of small bony plates protects the base of this anterior portion. A comb-like nutritive fold (*pecten*), absent only in the kiwi, projects from behind into the posterior chamber of the eye. A third transparent eyelid or nictitating membrane (not restricted to birds) is conspicuously developed, and can be drawn like a screen across the eye. It lies hidden in the anterior corner. Tear and other glands are present. The ear differs markedly from that of mammals in the absence of any external

Fig. 6.—Brain of Pigeon: a, fore brain; b, cerebellum; c, optic lobes; d, medulla oblongata; e, spinal cord; f, olfactory lobe; g, pituitary body; h, pineal gland.

portions. In the birds of prey, however, a membranous flap is present. The external opening is usually surrounded by a circle of fine hair-like feathers. As regards ear bones, only one (the columella) is present, and in this particular also the bird ear differs from that of mammals. The snail-like coil of the ear-cavity (the cochlea) is also much simpler. The (Eustachian) tubes which lead from the ear-aperture down to the mouth, unite before they open into the latter. The nostrils are usually situated at the base of the beak, but may occur further forward, and in the kiwi are situated at the very tip. In some cases they are guarded by bristles, in other cases prolonged into a tube, but are usually simple apertures. The nasal cavities may communicate with one another, and contain two or more gristly or bony scrolls. A peculiar nasal gland is present. The sense of smell is undoubtedly less developed than those of sight and hearing. Taste is also but slightly developed, and is discharged by the nerve terminations on the tongue, and by a soft patch of skin (*cere*) usually situated on each side of the base of the beak. In rare cases (e.g. in mud-grubbing birds) a much larger area of the Bill (q.v.) may remain soft and sensitive.

Fig. 7.—Head of Falcon, showing beak, nostril, eye, and ear; opening exposed by removal of feathers.

portion. In the birds of prey, however, a membranous flap is present. The external opening is usually surrounded by a circle of fine hair-like feathers. As regards ear bones, only one (the columella) is present, and in this particular also the bird ear differs from that of mammals. The snail-like coil of the ear-cavity (the cochlea) is also much simpler. The (Eustachian) tubes which lead from the ear-aperture down to the mouth, unite before they open into the latter. The nostrils are usually situated at the base of the beak, but may occur further forward, and in the kiwi are situated at the very tip. In some cases they are guarded by bristles, in other cases prolonged into a tube, but are usually simple apertures. The nasal cavities may communicate with one another, and contain two or more gristly or bony scrolls. A peculiar nasal gland is present. The sense of smell is undoubtedly less developed than those of sight and hearing. Taste is also but slightly developed, and is discharged by the nerve terminations on the tongue, and by a soft patch of skin (*cere*) usually situated on each side of the base of the beak. In rare cases (e.g. in mud-grubbing birds) a much larger area of the Bill (q.v.) may remain soft and sensitive.

Alimentary System.—The character of the food-canal differs widely in different birds, varying with the nature of the food. Even in one bird the difference of food at different seasons, such as the change from fish to grain in the gull, may be

associated with a marked change in the nature of the stomach. The beak may be helped by the tongue in taking up food, but in the absence of teeth no real mouth mastication takes place. The tongue varies widely in form, being not unfrequently notched and rough, and varies in size from

Fig. 8.—Beaks of various Birds:

the rudiment found in the pelican to the long protrusible organ of the humming-bird. Salivary glands open into the mouth-cavity, which in some cases (e.g. pelican) is enormously distended, and can hold quite a store of food. The gullet is soft and elastic, in obvious association with the downward

passage of unmasticated food. In many birds it dilates into a spacious thin-walled sack, known as the crop, in which large quantities of food can be stowed away. It is from the crop that pigeons obtain the soft milky stuff with which they feed their young. In most birds the succeeding portion of the canal is divided into two (and sometimes three) distinct parts—the glandular and the muscular stomach. In the first (the *proventriculus*) the food begins to be digested, in the second (the *gizzard*) it is subjected to grinding. The former is characterised by thick, soft glandular walls, and near it the blood-gland, known as the spleen, is situated. Most people are familiar with the large hard gizzard of fowl or pigeon, with its very thick muscular walls lined internally by firm horny skin. The cavity usually includes small stones, and by the approach of the two sides

Fig. 9.—Alimentary Canal of Pigeon:

a, crop; b, proventriculus; c, gizzard; d, d, intestine.

The cavity usually includes small stones, and by the approach of the two sides

the food is very effectively ground. The changes dependent upon food, above referred to, are expressed in the varying preponderance of glandular and muscular regions. The exit from the stomach is turned upwards (as in crocodiles), so as to lie very near the entrance. Of the long small intestine and the short large one, of the blind processes given off at the commencement of the latter, of the associated liver (very often without a gall-bladder) and pancreas, there is little of much interest to notice. The gut ends in a common chamber or cloaca, which also receives urinary and genital products. The back wall of this common chamber is connected with a peculiar sac with glandular walls, especially prominent in young animals, but of dubious import.

Vascular System.—The heart of birds shows a marked advance over that of reptiles, in the complete separation of arterial and venous blood. Like that of mammals, it is perfectly four-chambered. The blood-vessel arrangements also resemble those of mammals in the presence of a single main branch (*aortic arch*) conveying pure blood from the heart to the body; but this runs to the right instead of to the left. The most remarkable physiological fact about the blood is its high temperature of 100° to 112° F., greater than that of mammals by 2° to 14°. 'The polished feathers are bad radiators, the air entangled among them forms a bad conductor, and thus the heat is kept in.' The usual 'blood-glands' are present. There is only an incipient partition (*diaphragm*) between the anterior and posterior portions of the body-cavity.

Respiratory System.—The two lungs do not lie freely in a closed space, as in mammals, but are fixed to the back of the bird. They are further peculiar in the way the supplying air-tube (*bronchus*) branches in a tree-like fashion without breaking up into finer and finer forkings. The ends

other, as John Hunter showed, with the air-spaces found in the spongy bones. The windpipe or *trachea* is often very long and coiled, and is strengthened by gristly or bony rings. It sometimes comes into very close association with the breastbone, running through part of it in the swan. At its upper end there is, as usual, a larynx; but this is not the vocal organ of birds. Further down, at the point where the windpipe divides into the two bronchial tubes, lies the seat of all the music, the sing-box or *syrinx* (see the paragraph on Song).

The Excretory System.—A pair of three-lobed kidneys embedded under the shelter of the hip-girdle perform the usual function of getting rid of nitrogenous waste. They are connected by a pair of ducts (*ureters*) with the cloaca. There is no urinary bladder. The urinary secretion is semi-solid, and rich in uric acid.

Reproductive System.—The male reproductive organs (or *testes*) are paired, and lie in front of the kidneys. The left is very often larger than the right. They are connected by a pair of ducts (*vasa deferentia*) with the common chamber, the wall of which occasionally bears a copulating organ. The female organs are peculiar in this, that in the adult the left side predominates over the right. In the embryo two ovaries are present; in abnormal and in a few exceptional cases (diurnal birds of prey) they may persist; usually, however, the right wholly degenerates. And similarly with the ducts, but the rudiment of a right oviduct is present. The end of the left oviduct is expanded to receive the ova as they burst from the ovary; the upper part of the duct is glandular, and equips the eggs with albumen; the lower is firmer, and contributes the limy shell; and the end opens into the cloaca whence the eggs are laid.

Nutrition.—The food of birds varies greatly, not only in different birds, but also to some extent at different seasons. Some are vegetarians, feeding on the green parts of plants, and in these the intestine is as usual long. Some confine themselves to grain, and these have large crops and powerful gizzards, while others combine cereals with insects (usually then without crop), or with the green parts of plants. A few sip honey, and a large number feeding on fruits probably play an important part in the dissemination of seeds. In insectivorous and fruit-eating birds the crop is usually absent, and the stomach only slightly muscular. Others again are notoriously carnivorous, or feed upon fish and molluscs, and in these cases the glandular predominates over the muscular portion of the stomach. The kea (*Nestor*) of New Zealand, originally a fruit-eating bird, has recently developed an alarming fondness for the blood and fat of living sheep. The interest of the nutrition of birds is twofold: on the one hand, in relation to the modifications of the alimentary system; on the other hand, in respect to the rôle of birds in the economy of nature. The experiments of John Hunter on the changes in the stomach of gulls consequent on a change of diet have been corroborated and extended. Such changes appear to occur normally in nature. Food is also said to have an influence on colour—e.g. in bullfinches and parrots.

Locomotion.—Most birds use their wings in flight, the feather-covered arms being raised and depressed with great rapidity by means of the breast muscles already described. Every one who has watched birds is familiar with the marked differences in rapidity and mode of flight. It has been calculated that a common average of rapidity is about 40 to 60 feet per second, but records of the feats of carrier-pigeons, &c. certainly greatly surpass this. It seems probable that strong-winged birds, like eagles, can cover about 80 feet in a second. Buffon noted that they disappeared from sight in about three

Fig. 10.—Lungs of Bird :

a, base of trachea; b, b, bronchial tubes; c, branches of bronchi; d, blood-vessel.

of the bronchial branches are in connection with air-sacs which lie round about the lungs. These greatly increase the quantity of air which may be taken in; they are of use in warming it, and doubtless aid, not only by greatly reducing the specific gravity, but also on the heated-air principle of Montgolfier's balloon, in buoying the bird in the air. These air-sacs are large but thin-walled bags, nine in number (see AIR-SACS). They are connected on the one hand with the bronchi, on the

minutes. The importance of the air-sacs and spaces has been already noted. Strong birds, like the albatross and birds of prey, can not only fly very rapidly, but can sustain their exertions for long

Fig. 11.—Wing of Pigeon, showing primary (a) and secondary (b) feathers, and 'bastard wing' (c) at thumb.

periods, while many other birds rarely take prolonged flights, except during migration. The ostrich uses its wings to help it along in its rapid race; some aquatic birds, like the steamer-duck, use them as paddles, auxiliary to its legs. On the ground, birds vary greatly in rate and manner of progression, the swift strides of the ostrich, the rapid run of the partridge, the hopping of the sparrow are well-known illustrations of different gaits. That many birds are expert divers and climbers is also a familiar fact. See FLIGHT.

Respiration.—The great activity of birds is associated with very efficient respiration. Expiration, or the expulsion of used air, is managed by the contraction of breast and abdominal muscles, which compress the inclosed cavities and force the air from the sacs and lungs. When these muscles are relaxed the cavities again elastically expand, and fresh air rushes in by the windpipe to lungs and air-sacs.

Song.—With few exceptions, birds have a vocal organ, and are able to produce more or less variable sounds. The organ is, however, wanting in the running birds, such as the ostrich, and in the American vultures. The sounds produced are almost as varied as the different kinds of birds, and an expert ornithologist has little difficulty in identifying a great number of forms by their distinctive noises. That some chirp and others scream, that chattering describes the language of many and croaking that of others, that some boom and others bark, that the crows caw and the laughing jackass laughs, that the mocking-bird imitates and the parrot becomes able to articulate, and above all that the lark trills and the nightingale truly sings, are well-known illustrations of the variety of bird language. The weird cry of the curlew or whaup, the melancholy voice of the seamew, the gabble of ducks, the crowing of the cock, the soft cooing of the dove, the hoarse voice of the cornerake, the ecstatic melody of the bobolink, the cheerful notes of the blackbird, the educated music of the canary, are again a random selection of instances from an almost infinite medley. It is among the so-called perchers, songsters, or Insesores, that we find song really developed, and that for the most part in the males, and in highest degree at breeding time. Though the notes are not musically pure, many bird songs have been expressed in musical notation, and every one is familiar with imitations in word form.

In mammals the voice is produced by the

mechanism of vocal chords situated in the larynx at the top of the windpipe. In birds these vocal chords are never present, but their absence is compensated by the development of a sing-box (or syrinx) at the base of the windpipe. In some cases the sing-box is wholly produced from the base of the windpipe (or trachea)—e.g. in *Thamnophilus* and American Passerines; in a few cases the mechanism is confined to the beginning of the bronchial tubes (e.g. *Scolopastrix*); in the great majority of songsters the syrinx includes the base of the trachea and the tops of the two bronchi. The mechanism is a very variable one, and even in its simplest forms not to be understood by any verbal description unaccompanied by dissection of a few typical singers. To take a typical example of a lower larynx or syrinx of the last and commonest construction, we find (a) that the base of the trachea and the tops of the bronchi are altered by lateral compression or by expansion, by fusion of several of the strengthening rings, or by incompleteness of some of the same. (b) The end of the windpipe is divided by a bony ridge, rising up at the angle where the two bronchi unite, and forming the main stay of the resonating cavity known as the 'tympanum.' (c) From this bony ridge to the median surface of each bronchus stretches the 'internal tympanic membrane.' (d) Between the last tracheal and the first bronchial ring, or between a pair of modified bronchial rings, stretches a second 'external tympanic membrane.' (e) In singing-birds there is a third important inward projecting 'semi-lunar membrane.' (f) Besides these there are vocal membranes or folds of skin, projecting inwards in both bronchi. The tension of the membranes is varied by the action of special muscles; their vibration as the air passes over them causes sound; the note varies with their muscular state, with that of the tympanum, and with the column of air in the windpipe.

Singing is an unbidden expression of emotional energy. It is most marked at the high tide of sexual emotion during the breeding-season. It is best, sometimes solely, developed in the males, who use their powers to attract the females, and often vie with one another in so doing. In other cases the note is obviously used as language, expressing alarm and the like, for that some birds are able by voice to convey impressions to one another is indubitable. In so far as the song is an instrument and expression of sexual attraction, it falls to be included among those powers which have been strengthened and developed by sexual selection.

Moulting (q.v.).—After the strain of the reproductive period, or sometimes at the low ebb of mid-winter, the old feathers drop off, and birds undergo annual moult. The use of this in replacing breakage, and in furnishing a complete machinery for the flight of migration, is very evident; the cause is not yet sufficiently investigated. Moulting obviously presents some analogies with skin-casting and hair-shedding in other animals, and must be associated with some deep-seated constitutional change, such as its connection with the end of

Fig. 12.—Syrinx of Thrush:

a, trachea (opened below);
b, bronchi (with rings);
c, internal tympanic membrane; d, muscles;
e, nerve supplying muscles.

the breeding-season suggests. Besides this annual growth of new feathers, many birds exhibit double, and some triple moulting. The ptarmigan, for instance, changes its suit three times in the year, moulting after breeding into gray, changing this for white as the winter sets in, and acquiring in spring a third and most attractive set of feathers. In association with sexual attraction many male birds seem to undergo a partial moult, as the result of which they acquire those special decorations which are the index of a reproductive climax.

Reproduction.—Birds usually pair in spring-time, but to this rule there are many exceptions. Fertilisation is internal, and all birds are oviparous. The number of eggs is often in inverse proportion to the size of the bird. Several, such as the apteryx, lay only one; the doves and the birds of prey lay two or three, but the majority of birds many more.

The Sexes.—The male birds are often markedly different from the female. In the Bird of Paradise (q.v.), for instance, the two sexes are at first alike, but with successive moults and increasing maturity, the male becomes in colour and plumage a most marked contrast to the comparatively sober female. The contrast between peacock and peahen is a yet more familiar illustration of a very widely observed fact. In rare cases the female is the more brilliant. The male has also a richer and more varied voice, and in many cases the singing is all on his side. Both with song and with dance, by strains of love and display of charms, by the wildest excitement of aerial evolutions, and by the most grotesque of striking attitudes, the males strive to captivate the females. For the details of this sexual attraction, and for the importance of sexual selection in evolving decorations and charms, the reader may be referred to Darwin's *Descent of Man*, where the subject is very fully discussed. Birds associate together to very different degrees; thus, eagles live separately, the two sexes only coming together at breeding time; the doves live in pairs; many birds are similarly monogamous, but live in society, except during the breeding-season, while fowls and some running birds are polygamous, one male ruling over a number of females. See SEX.

Eggs.—The size of the egg is very generally proportionate to that of the parent, but there are many striking exceptions. The very centre of the egg contains what is known as white yolk which rises as a plug to the surface. This white spot, usually lying uppermost when the egg is opened, is the area (*blastoderm*) where by the multiplication and arrangements of cells the embryo chick is mapped out. The 'yellow yolk' is traversed by concentric

fluid white of egg or albumen, which is separated from the yolk by a (*vitelline*) membrane inclosing the latter. The fluid albumen is also disposed in layers, separated by fibrous networks, and almost every one is familiar with two thick sets of fibres (known as the 'tread') which extend from each end of the yolk into the surrounding albumen. In the lower portion of the oviduct (the *uterus*) the egg becomes, as we have already noted, inclosed in a limy shell. This is an organic structure and is two-layered. Its texture and microscopic characters differ in the various orders, and appear to be truly diagnostic. The shell is separated from the white of egg by a double membrane, the two layers of which become separate at the broader end, and leave a familiar air-space which increases with the age of the egg. The form of the finished egg varies from an approximately perfect sphere to more or less symmetrical ovals. In the uterus the shell usually becomes stained by complex secretions of pigment which in some respects resemble those of the blood and bile. As many as seven distinct pigments have been distinguished by Mr Sorby. It is necessary to distinguish the ground colour from the subsequent more or less circular markings, which become variously blotched and distorted by the movement of the egg in the uterus. The markings are not always constant, but vary with age and even in the same brood. The colouring is apparently to some extent protective against the sun rays, and varies also according to exposure. That the colour of the eggs often favours their being overlooked by enemies is a familiar fact. Though the older naturalists, before the collecting of eggs had been superseded by embryology, doubtless exaggerated the importance of their science of 'oology,' it is also certain that some important hints in classification have been afforded by the study of the characteristic colouring. The extraordinary enthusiasm exhibited by egg-collectors, from the time of Sir Thomas Browne's cabinet onwards, is a most remarkable side chapter in the history of science, which has been recapitulated in the lives of many of our famous naturalists, and indeed in the boyhood of almost every boy bred in the country. See EGG, CAGE-BIRDS, INCUBATION.

Development.—The development of the embryo bird will be discussed along with that of other backboneed animals (see EMBRYOLOGY); but a few general facts (with special reference to the fowl) may be noticed here. The egg is fertilised in the upper part of the oviduct before the coating of albumen is added to the ovum proper. The usual division commences in the lower part of the oviduct, shortly before the shell has begun to be formed. Owing to the vast amount of nutritive, as opposed to formative material, the whole ovum does not divide, but only a special part of it, known as the germinal disc. It is also noteworthy that the division proceeds somewhat unsymmetrically. The subsequent changes by which the different germinal layers are established, and nervous system, backbone, gut, muscles, and the organs generally are formed, cannot be here discussed. The development of the chick excited interest even among the old naturalist philosophers of Greece, and we have not finished the inquiry to-day. It was by observation of the embryo chick that Wolff first showed distinctly (in 1759) that development was a matter of gradual growth, and not the unfolding of a miniature ready-made organism. It was in regard to the fowl that Pander (1817) first drew emphatic attention to the different germinal layers, the distinctions between which are of such importance in understanding the process of development. On the development of the chick also, Von Baer (1828-37) partly based his great generalisation as to progress

Fig. 13.—Section of Fowl's Egg:

a, central plug of white yolk; b, position of germinal area; c, yellow yolk; d, white of egg; e, 'tread' or chalaza; f, air-space between outer membranes.

layers of white, which also forms a thin layer round the outside. As the egg passes down the upper portion of the oviduct it becomes coated with

from the simple to the complex, and showed that the passage of the embryo from one great stage to another corresponds to the successive steps which mark off fish from amphibian, amphibian from reptile, reptile from bird. This law we now express by saying that the individual development (*ontogeny*) is a recapitulation of the historic evolution of the race (*phylogeny*). Mr Parker eloquently compares watching the development of a bird to reading a palimpsest; under the more superficial characters are others (at an earlier stage) more primitive, beneath those others more primitive still, till the characters are seen to be distinctly reptilian, and so on backwards. The work thus begun by Wolff, Pander, and Von Baer has been vigorously continued; many of the greatest embryologists have contributed to the elucidation of bird development; in Britain Parker especially has, with marvellous patience and skill, followed the development of the bird skull. By the recent use of the contrivance known as the embryoscope, the development of the chick has been watched going on, and even experimented upon.

The chick is inclosed in an embryonic membrane known as the amnion, and has a large respiratory sac called the allantois. The nutritive yolk which is gradually absorbed is inclosed in a 'yolk sac.' When about to be hatched, the chick thrusts its beak through the egg-membranes, and breathes the air in the air-chamber. The lungs begin to work, and the allantois shrivels up. The Umbilicus (q.v.) becomes completely closed, and 'the chick, piercing the shell at the broad end with repeated blows of its beak, casts off the dried remnants of allantois, amnion, and serous membrane, and steps out into the world.'

The period of incubation, during which the parent, generally the female, but often also the male, sits in most cases constantly on the eggs, varies greatly, from ten days to eight weeks. The young birds may be at first naked, blind, and helpless, and are then fed by the parents till fledged (*Altrices* or *Insesores*)—e.g. Thrush, or they may be downy, active, and able at once to look after themselves (*Præcoeces* or *Autophagæ*)—e.g. Chick. In some cases, however, they are hatched downy, but remain for a while helpless. See EMBRYOLOGY.

Nests.—It is important to notice that the higher development of birds, as compared with reptiles, is associated with the production of fewer offspring, but at the same time with the enormous increase of parental care and sacrifice. If the young are to be developed within the eggs, the latter must be kept at an approximately constant warmth. In almost all cases this is effected by brooding. The comfort of the parents during the hatching period is secured by the nest, which becomes further necessary for the protection of the fledglings. The nest-building instinct is not indeed the exclusive property of birds, but occurs also among insects and fishes, not to mention the numerous cases where homes rather than nurseries are constructed by animals. But it is among birds that the instinct reaches perfect development. The prolonged period of brooding, the frequent helplessness of the young, the very common arboreal habit, the not unfrequent enemies, have necessitated a most varied series of nest-building contrivances. The nest is built before the eggs are ready to be laid, and in most cases the female takes the prominent part in its construction. But both in the building and in the subsequent brooding the male may do his share, or in some cases much more. Each species usually has its own peculiar style and material of construction, though this may be adapted to varying conditions. The nests are usually solitary, more rarely grouped, and very exceptionally (as among cassowaries and ostriches)

common property. Rooks, sea-fowl, herons, are familiar examples of breeding communities, while the sociable grosbeak, the republican swallows, and a few others, form even closer associations. The cuckoo and the cow-bird have managed by a sort of parasitism to shirk their task, and quite a number of birds lay their eggs in an exceptional manner in the nests of neighbours. The beak is the organ most used in construction, but the pressure of the body may round off the forming nest, and the feet may also be used. How comfortable a nest may be made inside every one knows; how adroitly hidden it may be by external decorations of moss and lichen is familiar to every nest-hunter. All who have opportunity should examine the cases of birds and their nests so beautifully arranged in the British (Natural History) Museum in London. The smaller birds usually build the more beautiful nests, and every variety occurs, from the comparatively careless hole in the sand made by the ostrich to the skilfully suspended and neatly fashioned nest of the tailor-bird.

Without entering into details of nest-construction, the following series given by Leunis may be noted. For details, such a work as Rev. J. G. Wood's *Homes without Hands*, and for theory, Wallace's essay on Nests in his *Contributions to the Theory of Natural Selection*, may be profitably consulted. It must at the outset be again noticed that habits vary considerably, as the very diverse nests built in different circumstances by falcon, eagle, heron, &c. well illustrate. Nests are shifted to suit food-supply, and vary in structure according to the available material. And again, since nest-building is obviously an acquired habit, which gradually rewarded the species in the greater success of both parent and offspring during breeding time, it is natural to find it dispensed with in many cases where the nature of the situation rendered no actual nest necessary, or where the birds for some other reason have never learned the habit. Some sea-birds, like the auk, simply lay on the rocky ledges of their haunts; some ground-birds simply deposit their eggs on the bare soil.

(1) *Burrowed holes* are made by sand-martins, bee-eaters, penguins, kingfishers, and many others. The prairie-owl, living in the burrows of the prairie-dog and of the armadillo, is a well-known example of peculiar habit, and in the first case of curious partnership. (2) *Ground-nests*, generally of the simplest character, with rough and scanty accumulation of nest material, are made by swans, ducks, geese, fowls, gulls, waterhens, cornerakes, &c. (3) *Mud-nests*, constructed from damp earth, are well illustrated by the house-swallows, blue-creeper, flamingo, &c. The common singing thrush is well known to make a firm nest of clay and cow-dung mixed with moss. (4) *Carpenter-nests*, formed with more or less preparation in the holes of trees, are used by woodpeckers and a few other arboreal birds. (5) *Platform-nests*, simply consisting of flat seats, are formed by the ring and turtle doves, by eagles, storks, and cranes. In some parts of the Continent the flat nests formed by the storks on the tops of buildings are familiar enough objects. (6) *Basket-nests* are such loosely interwoven constructions of grass, stems, twigs, &c., as are made by crows, missel-thrushes, and most singing-birds. The green weaving-birds (*Plorœus pensilis*) hang their loosely woven nests, with downward directed opening, on the Madagascar trees. The South African republican birds (*Philetarus socius*) form hundreds of hanging nests on the branches, under the shelter of a common thatch. (7) *Woven nests* are the more delicately constructed and really woven constructions of wool, hair, bark, grass, &c., which are made by

such birds as the goldfinch, the Baltimore bird, and very many others. (8) *Sewed nests*, composed of leaves sewed together by the beak as needle, are well illustrated by various species of Icterus, and by the Indian tailor-bird (*Orthotomus ben-nectii*). (9) *Felt-work nests* are woven from the wool of plants or animals, sometimes with other material in addition; the humming-birds and the bullfinch form beautiful nests of this fashion. (10) *Cement-nests* are bound together by a viscid and very adhesive secretion, which is mixed with saliva, and used to glue the materials of the nest together. The nests of the American swallow, the edible birds' nests of the Salanganis, sought after as luxuries by Chinese and others, are of this cemented type. (11) *Dome or moss nests* are roofed in above, and have an entrance on the side. The common wren, the water-wagtail, and the tits build on this principle. The beautiful bottle-shaped nest of the titmouse is one of the best examples. (12) The *parasitic* habit is well known among cuckoos and cow-birds. The nest of another bird is utilised to the future loss of the rightful inmates, and with obvious economy of labour on the part of the intruders. Thus sparrows usurp the nests of swallows, and starlings those of woodpeckers. Pheasant and partridge eggs are sometimes found in the same nest, and the same has been observed in many cases—e.g. gull and eider-duck. When artificial nests are forthcoming, birds are glad to be relieved of the labour of construction, and different birds thus sometimes share a common box. The resorts of birds, when convenient nooks are available, are often extremely curious.

Migration.—It is a well-known fact that comparatively few birds (at anyrate, outside of the tropics) remain in the same place all the year round. They do not hibernate, but migrate on the approach of cold. Some we know as winter visitors returning north again in spring, most we know only in summer, for in autumn they fly to the warmer south; a third set we call 'Birds of Passage,' for these we only know somewhat incidentally as they pass through on their way elsewhere. Thus the swallow, the cuckoo, the nightingale, &c. come to Britain in summer and breed there, being winter residents farther south; the fieldfare, jack-snipe, bean-goose, redwing, &c. reach Britain in winter, being summer residents and breeders farther north; while the little sandpipers are familiar examples of the true birds of passage which we know only for a short time as they rest on our shores in their journey south in autumn, and north again in spring. These three classes are obviously only different cases of one fact of Migration (q.v.). As this will be discussed separately, only the general facts are here to be noticed. Almost all birds are in some degree migratory. Those which breed in the equatorial regions are the chief exceptions, and even they pass from hill to valley and back again. Forms, too, which seem to be constant residents of a non-tropical country are in many cases known to exhibit a partial or a very local migration. This is true, for instance, of the common wren and the red grouse in the north of Scotland. All birds breed in the colder regions of their migration. Changes in food-supply and temperature are the most important conditions impelling them to shift their habitats. The general trend of migration is always, as indicated, towards the equator in autumn, from the equator in spring; but the investigations of the British Migration Committee have clearly shown that the courses often come to be circular. The flight is the more universal in a country, the more marked the contrast between summer and winter. The annual migration from breeding areas too cold for winter

residence and food-supply to warmer subsistence areas cannot be understood apart from the history of climates. When the European climate was more equable, it was virtually indifferent to the birds where they went. As it grew colder, the birds had to fly farther and farther south every few winters. Migration has become an inherited habit, for they set about it before the impelling conditions are directly present. According to Wallace, natural selection has played an important part in confirming this habit. Many facts about migration are still utterly obscure. The power birds have of flying straight and of returning to the same locality is very marvellous. It must be remembered that a continuous tradition is sustained; those who have made the journey before guide the others. Doubtless they have memory for great landmarks. They fly across the shallower parts of the Mediterranean, where a chain of islands in this submerged tract long remained to guide them. The smaller birds usually keep nearer the ground; but it must not be forgotten that the flight is usually mostly accomplished by night. Birds generally meet in concourses, and migrate in flocks. Only a few fly alone. Sometimes the old males remain, while the others 'flit.' The return northwards is more rapid, without young ones or weaklings. The males often return first.

Intelligence and Emotions.—As birds have a full active life, with considerable variety of function, in usually complex environment, since, as we have already noticed, their sense-organs and nervous systems are highly developed, considerable exhibition of intelligence is to be expected. They seem to have great vividness of sense impressions, to judge from their power of recalling old haunts and old friends. Birds often return to the same place season after season, and they have been known to recognise an owner after the lapse of years. Their quickness of ear and power of retention are evidenced by the power some possess of learning to repeat sounds, both words and tunes. Some have exhibited marked fondness for music, and the æsthetic tastes of the Bowerbird (q.v.) excite deserved admiration. Much more is known in regard to their marvellous hereditary, general, and largely automatic reasonable habits or 'instincts,' than in regard to their power of individually adapting their conduct to novel circumstances. Their beautiful and adroit contrivances of nest-building are very familiar instances of the former, but many instances of the latter have also been recorded. Mr Romanes has collected numerous illustrations of curiosity, imagination, forethought, and instruction by experience. He notes many interesting cases of their special devices in obtaining food, in avoiding capture, and in nest-building. His valuable treasury of sifted facts ought to be consulted on this subject.

As to feelings, it is hardly necessary to refer to their unexampled exhibition of sexual emotion in song and dance, parade and display, or to the marvellous parental love and sacrifice expressed in their nest-building labours, in their prolonged incubation, and in their care for and courage in defending their brood. Subtler emotions of jealousy, both in connection with and altogether apart from sex, of affection for owners or associates, of sympathy for wounded or enfeebled fellows, are also not rarely exhibited. That a bird singing continuously for hours does not represent a rare height of emotion is not to be believed. It may be fairly said that the joyous song of the lark 'at heaven's gate' is an eloquent expression of emotion only surpassed perhaps by human music.

Distribution in Space.—It is a curious fact that though birds are able to fly far and wide, and are

much less settled than most animals, it was in relation to them that the first great essay towards an understanding of distribution was made. In 1857 Mr Selater based, upon the facts of the distribution of perching birds (*Passeres* or *Insectores*), a division of the earth into six great regions, with characteristic fauna. These regions he termed Palearctic, Ethiopian, Indian, Australian, Nearctic, and Neotropical. For an account of the birds which especially predominate over these great regions, or others with somewhat altered limits, the reader must be referred to the works of Murray and Wallace on Geographical Distribution of Animals, and to the convenient summary of facts given by Heilprin (*Inter. Science Series*). Some genera of birds are very widely distributed, and almost universally represented; others, like the birds of paradise and the humming-birds, are peculiarly restricted. It hardly needs to be stated that birds have unusually great facility of dispersion; that they are more numerous in the warmer countries; that according to the nature of the region, different physiological types will preponderate—e.g. insect-eating birds in the tropics, and fish-eating swimmers in the northern seas.

Distribution in Time.—(1) In the Triassic strata of New England, various kinds of footprints occur which most naturalists now regard as reptilian, though others are inclined to see in some of them the earliest hints of birds. (2) The oldest known birds are found in the Upper Oolite, the well-known *Archaeopteryx* (q.v.), from the Solenhofen lithographic slates, and *Laopteryx prisca*, from 'a nearly equivalent horizon in the Wyoming Territory' of the western United States. The long feathered tail, the unfused metacarpal bones, the toothed jaws, and other features of *Archaeopteryx*, are exceedingly important pristine characters. (3) In the Middle and Upper Chalk, numerous fossil birds have been discovered, especially by Marsh. These are grouped together in a somewhat mixed division of toothed birds, or *Odontornithes* (q.v.). Of these the most remarkable are *Hesperornis* and *Ichthyornis* (q.v.), both with teeth. The latter had biconcave fish-like vertebrae, well-developed wings, and a keeled breastbone. The former had vertebrae much like those of modern birds, rudimentary wings, and, as one would expect, no keel on its breastbone. Its teeth were not implanted in distinct sockets as in *Ichthyornis*, but lay in a longitudinal groove of the jaw. *Apatornis* was another remarkable form, and *Enaliornis* has been found in Europe in the Upper Greensand of Cambridge. (4) In the Tertiary deposits birds become more numerous, and like those now existing. Representatives of modern genera occur from the Eocene onwards. Many types, such as the great running birds, now with restricted distribution, are found in regions far from their present habitats. A giant goose-like form, *Gastornis*, apparently exceeding the ostrich in size, has been found in France and Britain. Heilprin notes how *Leptosomus*, type of a small family now restricted to Madagascar, is found in the Eocene deposits of France. In the Eocene also occur *Megalornis*, little smaller than an emu; *Dasornis*, uniting ostrich and moa; *Odontopteryx tobiasiensis*, 'with dental armature recalling the toothed birds' of the chalk. A crane-like genus, *Alatornis*, is frequently represented in American strata. Giant forms disappear, the running birds are driven into corners, teeth degenerate and wings develop, as the modern bird fauna is gradually approached. Those who wish to read the full story should consult especially the writings of Marsh, and in the first place convenient summaries, such as that of Heilprin.

Sub-fossil and Historically Extirpated Birds.—Within comparatively recent (semi-historic)

times, the 'moas' of New Zealand (*Dinornis* and *Mionornis*), the *Epyornis maximus* of Madagascar, the Australian *Dromaeornis* (ancestor of the emu), and others have disappeared. Much more recently the dodo of Mauritius, the solitaire of Rodriguez, the crested parrot and the *Aphanapteryx* of Mauritius have been exterminated. Under separate articles some of these will be discussed. Thoughtlessness and cruelty are unfortunately tending to the extermination of some other forms.

Classification.—In 1880 Mr Selater estimated the number of extant bird species at 10,139, and Gray's estimate was somewhat higher. To these some 200 known fossils have to be added. The classification of these numerous forms is still a matter of the greatest difficulty. The older classifications were based on the habits, or on comparatively trivial characters; but as this physiological classification has been gradually improved, it has come to be not so inconsistent as formerly, with the anatomical classification suggested by Huxley. In his famous paper on the 'Classification of Birds,' *Proceedings of the Zoological Society*, 1867, Huxley grouped birds according to certain features of the skull, and though this may seem too narrow a basis, it must not be forgotten, as W. K. Parker remarks, 'that the structures of the skull and face govern the whole body, as it were; every other part of the organism corresponds to what is observable there.' But even when the great groups are marked off on this basis, there remains the huge difficulty of the genera and species. The difficulty of satisfactory diagnosis is due to the narrow range of modification. 'One bird is so like another,' say the non-ornithologists, and Professor Huxley confesses the same in saying that 'the structural modifications which the specific forms present are of comparatively little importance; any two birds which can be selected differing from another far less than do the extreme types of the lizards.'

While there is general agreement in distinguishing three great divisions of (1) ancient birds, like *Archaeopteryx* (*Saururus*); (2) running keel-less birds, like ostrich (*Ratitae*); and (3) keeled flying birds (*Carinatae*), the divergence of classification observed in grouping the last of these three divisions is very great. In many works, especially text-books, the old orders of swimmers (*Natatores*), waders (*Grallatores*), scratchers (*Rasores*), climbers (*Scansores*), perchers (*Passeres* or *Insectores*), and birds of prey (*Raptores*), are still followed. In other cases some of these are retained, and others split up or rearranged in smaller orders, and a dozen or more established in all. It seems therefore most useful simply to append the classification of Huxley, with examples showing their relation to more familiar divisions.

- I. *Saururus*.—Metacarpals not fused. Tail longer than body. Often with teeth—e.g. *Archaeopteryx*.
- II. *Ratitae*.—None of preceding characters. Flat unkeeled breastbone—e.g. (1) the kiwi (*Apteryx*), with a big toe; (2) the 'moas', cassowaries, and emus without a hallux; (3) the ostriches, differing from the preceding in having a long upper arm (humerus), and two (not one) clawed digits—the American ostriches or *Rheas*, with ischia (see hip-girdle) united, but pubes free, and the true ostriches or *Struthios*, with the ischia free, but the pubes united.
- III. *Carinatae*.—Ordinary birds with keeled breastbone.
 1. (a) *Dromaeognathae*.—Vomer broad behind, interposed between pterygoids, palatines, and basisphenoid rostrum—the Tinamous.
 - (b) (2-4) Vomer narrow behind, pterygoids and palatines articulating largely with basisphenoid rostrum.
 2. *Schizognathae*.—Maxillo-palatines free, vomer truncated in front. Plovers, gulls, penguins, cranes, fowls, sand-grouse, pigeons, hoazins, goatsuckers, humming-birds.
 3. *Æthiognathae*.—Maxillo-palatines free, vomer truncated in front. Part of Geranomorpha, the Hemipods, swifts, Passerine birds.
 4. *Sauvognathae*.—Vomerine halves permanently distinct, maxillo-palatines arrested (except in woodpeckers, united more or less completely). Woodpeckers, birds of prey, jarrots, cuckoos, kingfishers, trogons, goose-like birds, flamingos, storks, cormorants.

While the meaning of the terms can only be appreciated with the skull in hand, the above classification is independently of value as showing what orders of birds are on anatomical grounds most nearly related.

Pedigree.—It is generally allowed that birds have risen out of reptilehood. Such an origin is suggested not only by the general fact that 'reptiles' in the wide sense form the nearest distinctly lower class, but by resemblances of structure revealed in anatomical research, and still more by the study of bird embryology. But the crowning evidence in favour of this origin is found in the primitive characters of the first known bird (*Archæopteryx*, q.v.), and by the series of forms connecting flying saurians and toothed birds. Birds are derived from the ancient reptiles or saurians known as *Deinosaurs* or *Ornithoscelida*. These lead up to the primitive birds or *Saurura*, from which two branches diverge, represented by the keelless birds (*Ratitæ*) on the one hand, and by the keeled birds (*Carinata*) on the other. To discuss the nature of the step by which birds took wings and rose out of reptilehood, is to raise the whole problem of organic progress. To refer the step, as Buffon did, simply to a change in the quantity of carbonic acid gas in the atmosphere, is to give the process a false simplicity. To assume the accumulation of reptilian variations by natural selection in the struggle for existence, is the consistent Darwinian view. It is probably more correct to regard the incipient birds as, so to speak, 'fevered' representatives of reptiles progressing in the direction of greater and greater constitutional activity. Flight would be at first spasmodic, but as the structures became modified by function, would gradually become more constant and less pathological. The high temperature, the feathered skin, the flight, the hollow bones, the long rest of brooding, are probably all expressions of one predominant constitutional tendency. It must also be noted that the sacrifice of parental care justifies itself in the success of the brood. See *EVOLUTION*.

Economic Importance.—In their connection with other parts of the web-like world of life, as well as for their own sakes, birds are of much practical importance. Though eagles are sometimes destructive of lambs, the birds of prey more than make up for this by keeping down the vermin; though many birds rob fruit-trees, devour seeds, and pillage growing crops, their services in keeping away plagues of insects more than counterbalance the damage they do. That some (e.g. humming-birds) visit flowers and act probably as pollen-carriers, and that others aid in the dispersion of seeds, are minor offices. That the flesh and eggs of many, both wild and more or less domesticated, are common articles of food; that the down and feathers of some are in common use for comfort and decoration; that the excrement of others forms the useful manure known as guano, are facts familiar to all. In exceptional cases, birds may be of more curious utility, a variety of pigeons discharges the functions of a letter-carrier, falcons used to be much employed in sport, the nests of one form are eaten, and some birds are kept for amusement and decoration. And when we think of their beauty and song, we must allow that human life would be poorer without them.

Conclusion.—In many centuries, and now more than ever, birds have been studied by the naturalist. The perfection of their structure, the variety and ingenuity of their habits, and in later days the fact of their lofty ascent from lowly parentage, have afforded material for thousands of researches which, in a pre-eminent degree, have been labours of love. In the eyes of simpler men, unacquainted with the technicalities of science, the majority of

birds have for long seemed the most delightful of animals. Apart from their importance as beneficial or hurtful, apart from matters of food and sport, and apart from their ancient augural significance, birds have been universally allowed to possess peculiar charms. Their ethereal habit, their general vivacity, their grace of structure, the beauty of their plumage, the music of their song, the range of their intelligence and emotions, the mystery of their migrations, and other features, combine to make birds the first and last favourites of man. To the artist too they have supplied a wealth of colour, a variety and gracefulness of form, a suggestive beauty of pose and attitude which are not elsewhere equalled. Nor is it necessary to say that just as some of the greatest ornithologists have been at the same time poets, so most poets have been also ornithologists, or at least bird-lovers. To poets of every age and country birds have been 'symbols and suggestions;' although to too many they have been nothing more. They are emphatically the poet's animals; still he is often ignorant of their habits, according to Phil Robinson's indictment in *The Poets' Birds* (1883).

Literature.—Of the immense literature on birds, the following may be noted:

E. Alix, *Appareil Locomoteur des Oiseaux* (for mechanism of flight); Balfour's *Embryology*, vol. ii. (for development); Brehm's *Bird Life*, &c. and *Book of Birds*; Brewer, *North American Oology* (for eggs); British Museum, *Catalogue of Birds*; Bronn's *Thierreich*; Cassell's *Book of Birds and Natural History* (Martin Duncan); Darwin, *Descent of Man*, &c. (for sexual selection); Foster and Balfour, *Elements of Embryology* (for development); Gould's *Birds of Australia* (for reference); Gray and Mitchell, *Genera of Birds* (for reference); Hewitson, *Eggs of British Birds*; Huxley, *Anatomy of Vertebrate Animals* (for structure and classification); Ibis: *Journal of Ornithology*; Jerdon's *Birds of India* (for reference); Leunis, *Synopsis des Thierreichs* (for genera); Macgillivray's *British Birds* (for anatomy and genera); A. Newton, 'Birds,' *Ency. Brit.* (for distribution, &c.); Owen, *Anatomy of Vertebrates* (for structure); W. K. Parker, 'Birds,' *Ency. Brit.* (for structure and development); J. G. Romanes, *Animal Intelligence, Mental Evolution of Animals*; H. Seebohm, *A History of British Birds, with coloured illustrations of their Eggs*, vol. i.-vi. (1886); A. R. Wallace, *Contributions to Theory of Natural Selection, Philippine Islands*, &c. (geographical distribution of animals); J. G. Wood, *Homes without Hands*, &c. (for nests and general life); Yarrell's *British Birds*.

Bird, EDWARD, an English *genre* painter of considerable celebrity, was born at Wolverhampton in 1772. On the expiration of his apprenticeship to a maker of tea-trays in Birmingham, where his duty was to ornament the trays with flowers and shepherds, he established himself as a drawing-master in Bristol. In 1809 he sent to the Royal Academy a picture called 'Good News,' which brought him into notice; and two of his pictures, the 'Choristers Rehearsing' and 'The Will,' having procured him influential patrons, henceforth his reputation was secure, and ere long he was elected a Royal Academician. Other pictures were the 'Field of Chevy Chase the day after the Battle,' his masterpiece; the 'Death of Eli,' a number of rather poor Scripture subjects; and the unfinished 'Embarkation of Louis XVIII. for France.' He died in 1819. His reputation now depends on such of his works as 'The Blacksmith's Shop,' 'The Country Auction,' 'The Village Politicians,' and 'The Young Recruit.'

Bird, ISABELLA (Mrs Bishop), an adventurous lady traveller, long resident in Edinburgh, visited Canada and the United States in 1854. During a six months' residence in the Sandwich Islands, from time to time she sent home glowing letters describing what she saw and did, to a sister in Edinburgh. From such materials most of her

books of travel have been compiled. Her lively and picturesque narratives of journeys made to the Rocky Mountains, to the aborigines of Yezo, to Persia and Kurdistan, to Tibet and other parts of Asia, have been very extensively read. The daughter of the rector of Tattenhall in Cheshire, she married Dr Bishop of Edinburgh in 1881. Since her widowhood she has continued her travels and her work at home and abroad on behalf of philanthropic and missionary objects. She has lectured on many platforms, was elected the first woman F.R.G.S., and is also a F.R.S.G.S. Among her books are *The Englishwoman in America* (1858), which appeared anonymously; *Six Months among the Palm Groves of the Sandwich Islands* (1875); *A Lady's Life in the Rocky Mountains* (1879); *Unbeaten Tracks in Japan* (1880); *The Golden Chersonese* (1883); *Persia and Kurdistan* (1891); *Among the Tibetans* (1894); *Korea and her Neighbours* (1898); *The Yangtze Valley* (1899).

Bird. ROBERT MONTGOMERY (1805-54), practised for a year as a physician, but, turning to literature, wrote three tragedies, *The Gladiator*, *Oraloooa*, and *The Broker of Bogota*; and a series of novels, comprising *Calvaria* (1834) and *The Infidel* (both dealing with the Spanish conquest of America), *The Hawks of Hawk Hollow*, *Sheppard Lea*, *Nick of the Woods* (1837, a tale of Kentucky during the Revolutionary War), *Peter Pilgrim* (short stories), and *Robin Day* (1839).

Bird. WILLIAM. See BYRD.

Bird-catching Spider. a name originally given to a large spider, *Mygale aricularia*, a native of Brazil, Cayenne, and Surinam; but now more extensively applied to a number of large species of *Mygale*, *Epeira*, and perhaps other genera. The body of *M. aricularia* is nearly 2 inches long, very hairy, and almost black. When the feet are stretched out the animal occupies a surface towards a foot in diameter. The hooks of its mandibles are strong, conical, and very black. This giant spider lives in clefts of trees or in hollows between stones, where it spins a muslin-like tubular nest. During the day the *Mygale*

Bird-catching Spider (from Bates).

lurks in the wide porch of its house, but issues forth at night to hunt for its prey, which, according to Bates and others, really includes small birds. They are large enough to be led about by children as playthings. It is probably a species of this genus that Dampier mentions as found in Campeachy, the fangs of which, 'black as jet, smooth as glass, and at their small end as sharp as a thorn,' are said by him to be worn by some persons in their tobacco-pouches to pick their pipes with; and to be by others used as toothpicks, in the

belief of their having power to expel the tooth-ache.

Mygale or *Aricularia* belongs to that section of spiders in which there are four breathing organs instead of the usual two. The members of this tribe do not form a proper web, but live in holes in the manner above described, and gain their livelihood by hunting. But even the quieter web-spinning spiders (e.g. *Epeiridae*) seem to manage occasionally to capture birds. Their toils are occasionally many feet long, and sufficiently strong to impede travellers in the forest, so that it is little wonder that humming-birds, and even larger forms, are sometimes entangled. See SPIDER.

Bird-cherry (*Prunus Padus*) is a small tree growing wild in the moist woods in Britain and through the palaearctic region. It is easily recognised by its abundant racemes of small white flowers and deciduous leaves. The drupes are small, unpalatable save to birds (whence the popular name) and schoolboys, but are sometimes used to colour wine and brandy, and are said to be eaten in Siberia. In Scotland the common name is *Hagberry*. A larger but closely allied species (*P. virginiana*), of which the fruit is used to flavour pemmican, has been introduced into Britain. The wood of both species is esteemed by cabinet-makers.

Bird-lice, a popular name for a family of insects (Mallophaga), often placed beside other lice in the order Hemiptera. These external parasites are louse-like in form, usually with a distinctly separated front ring in the breast region (prothorax), with 3-5 jointed antennae, with biting mouth organs, and more or less of a sucking mouth. They live on the skin of birds and mammals, and eat young feathers and hairs, and also blood. *Trichodectes canis*, *Philopterus versicolor*, *Liothecium anseris*, *Menopon pallidum*, are common species. See LOUSE.

Birdlime is a viscid and adhesive substance, which is placed on twigs of trees or wire-netting, for the purpose of catching the birds which may alight thereon. A common practice is to place a decoy or tame bird in a cage near where the birdlime is spread; the wild birds, attracted to the spot by the song of the tame bird, get entangled with the birdlime. It is also extensively used for catching mice, and even rats, in houses, where poison is objectionable. The birdlime is spread on a board, some toasted cheese placed in the centre, and the trap laid on the floor. The mice in endeavouring to reach the cheese, are held fast by the feet, and may be destroyed. The substance is generally prepared from the middle bark of the holly, mistletoe, or distaff-thistle, by chopping up the bark, treating it with water, boiling for several hours, straining, and lastly exposing it to fermentation for several weeks, when a gelatinous muci-lage is obtained, consisting mainly of a substance to which the name *viscin* has been applied. A second mode of preparing birdlime is to employ ordinary wheat-flour; place it in a piece of cotton cloth; tie up the ends, so as to form a bag; immerse the whole in a basin of water, or allow a stream of water to flow upon it; and repeatedly squeeze the bag and its contents. The result is, that the starch of the wheat-flour is pressed out of the cloth bag, and an adhesive substance named *gluten* is left on the cloth. This substance resembles that prepared by the previous process in its properties; but the former mode of preparing birdlime is a much cheaper plan, and is that generally followed.

Bird of Paradise, the common name of a family of birds (Paradisæidæ), found chiefly in New

Guinea and neighbouring islands, and remarkable for splendour of plumage. In all other respects, however, they are very closely allied to the crow family, Corvidæ (q.v.), to which they exhibit a great similarity, not only in the characters of the bill, feet, &c., and in general form, but also in their habits, and even in their voice. They have been the subject of many fables. The state in which their skins are usually exported from their native islands, gave rise to the notion that they were destitute of feet; and free scope being allowed to fancy, it became the prevalent belief that they spent their whole lives floating in the air, except when perhaps they suspended themselves for a little by their long tail-filaments from the uppermost branches of trees. They were supposed to feed on dew and vapour, or more substantially on the nectar of flowers. Some of them do, indeed, feed partly on the latter. Antony Pigafetta, who accompanied Magellan in his voyage round the world, described them as having legs, and stated that these were cut off as useless in the preparation of the skins; but his statement was not credited, and Aldrovandus went the length of accusing him of an audacious falsehood. Most of the characters ascribed to birds of paradise are simply to be regarded as imaginative revelling in the absence of facts; but it is also possible that some of the fables are in part due to the desire of the inhabitants of those islands in which they are found to increase the value of their skins as an article of merchandise. A sort of sacred character being attached to them, they were employed not merely for ornament, but as a charm to secure the life of the wearer against the dangers of battle. Mr A. R. Wallace also points out that the Malayan traders, from whom the birds were usually bought, never saw 'them alive, knowing them indeed by the name *Burong mati*, or 'dead birds.' The people of Ternate call them *Manuk dewata*, or 'birds of God,' which name Buffon modified into *Manucode*. In different languages they are known by names signifying birds of the air, birds of the sun, &c. In 1760 Linnaeus described the largest species, *Paradisca apoda*, and also referred to the King Bird of Paradise. The list was gradually increased, but our real knowledge of the group dates from Mr Wallace's visit to New Guinea in 1857-58. Since then the quest has been followed up with enthusiasm.

The Paradisidæ are comparatively small birds, but their spreading feathers are often of great length. Though allied to crows and starlings, the adult males are in beauty unsurpassed even by humming-birds. Tufts of bright feathers spring from beneath the wings, from the tail, or from the head, back, or shoulders. Trains, fans, and exquisitely delicate tress-like decorations occur abundantly, and the gracefulness of the plumage is enhanced by the brilliant colour and metallic lustre. The females are plain, sober-coloured birds, and it is only with maturity, and after successive moults, that the males acquire that brilliancy of plumage which they exhibit to such advantage in their courtships. The true birds of paradise feed on fruits and insects, and are practically omnivorous. Their mode of life is more or less gregarious. They are intensely active, flitting about the whole day long. There is still lack of information in regard to nests and eggs. Some of them may be readily kept in confinement.

The birds of paradise are usually grouped in two divisions—the Paradisidæ proper and the long-beaked Epimachidæ—but Wallace unites these in one family. The former appear more nearly related to the crows, the latter to the hoopoes. Among the Paradisidæ proper, the following species deserve special record. The Great Bird of Paradise

(*Paradisca apoda*) is the largest species, measuring about a foot and a half in length. From beneath

The Great Bird of Paradise (*Paradisca apoda*).

the wings of the male there springs on each side a rich tuft of long plumes, sometimes 2 feet in length. The gorgeous colours, from golden orange to blackish violet, baffle brief description. 'The loud, shrill note is the most prominent and characteristic animal sound in the Aru Islands.' The natives shoot the males with blunt arrows when they are displaying themselves in courtship. So preoccupied are they that many may be shot before the thronging rivals take alarm.—The Lesser Bird of Paradise (*P. papuana*) is smaller and predominantly yellow, except on the breast, which is purpled. The females are white below, and so are the young males. They gradually become more brown and more handsome. This species is very frequently used for ladies' head-dresses. Its home is in New Guinea and adjacent islands. Wallace brought two live specimens to Britain, and they lived for one and two years in the Zoological Gardens in London.—Among closely related species is the Red Bird of Paradise (*P. rubra*), restricted to the island of Waigiu, near New Guinea. It is about 14 inches long, and the side plumes are rich crimson. The two middle tail-feathers form stiff black ribands, about 22 inches long. Wallace notes this bird as one of the most vivid instances of the development of colour and plumage through the selective action of the females. The natives catch them by an

King Bird of Paradise (*Paradisca regina*).

ingenious snaring contrivance.—The King Bird of Paradise (*Paradisca regina*, also called *Cicinnurus*

regius) is much smaller, only about 6 inches long, but is even more brilliant in plumage. The two middle feathers of this living gem are wire-like shafts, about 6 inches long, bearing at their extremities a spiral emerald disc. The females and young males are, as usual, very plain.—The Magnificent Bird of Paradise (*Diphyllodes speciosa*) has a curious double mantle on its back.—The Superb Bird of Paradise (*Lophorina atra*) is yet rarer and more brilliant, and bears a most extraordinary shield (like another pair of outspread wings) on the back of its neck.—The Six-shafted Bird of Paradise (*Parotia sericeus*) is adorned in many ways, but especially by six slender feathers springing from the back of the head and ending in oval webs. Wallace discovered a beautiful bird, which he called the Standard-wing (*Semioptera wallacei*), especially distinguished by a pair of long narrow white feathers, which spring from the bend of the wing, and are capable of being erected at pleasure.

Among the Epimachidae, or Long-billed Birds of Paradise, one of the most remarkable is the Twelve-wired Paradise Bird (*Scleracides alba*). About twelve posterior plumes have the midrib elongated into black wires, which curve backwards for about 10 inches. The female is not so plain as in most other species. The males are solitary in habit. These birds frequent flowering trees, are almost ceaselessly in motion, and feed to a large extent on the nectar of flowers. The great Epimach, or Long-tailed Paradise Bird (*Epimachus magnus*), 'has a magnificent tail, more than 2 feet long, glossed on the upper surface with the most intense opalescent blue. Broad brightly coloured plumes spring from the sides of the breast. The rifle-birds of North Australia (*Ptiloris*), and the paradise oriole are not distinctly related to the birds of paradise.

These marvellously beautiful birds have some commercial importance. 'They are the monopoly of the chiefs of the coast villages, who obtain them at a low rate from the mountaineers, and sell them to the Bugis traders.' The skull and feet are usually removed, the skin is wrapped up in palm leaves, and dried in a smoky hut. The colour is often half spoiled in the process. That the feathers are used for head-dress decoration has been already noticed.

The scientific interest of these birds is centred in the relation of the beauty of the males to their highly developed art of courtship. Wallace gives a vivid description of the excitement and display at pairing time. They meet in what the people call 'sacaleli,' or 'dancing parties,' on wide-spreading forest trees, with large but scattered leaves. A dozen or twenty fully-plumaged males then display their beauty in every variety of attitude and motion. It is believed that the males were originally like the females, as they generally are when young. Changes in colour and form gave certain males a preference in the eyes of the selecting females. The more attractive became the more successful breeders, and thus the development of their beauty is laid to the credit of their courtship. The real origin of the colour in the mature males still requires elucidation; the theory of sexual selection only shows how changes once started might be gradually accumulated and enhanced.

The birds of paradise are restricted in distribution as above noticed. Their home (New Guinea) is rugged and mountainous, and in its recesses almost inaccessible. The people are savages. 'In such a country,' says Wallace, 'and among such a people, are found these wonderful productions of nature, the birds of paradise, whose exquisite beauty of form and colour, and strange development of plumage, are calculated to excite

the wonder and admiration of the most civilised and the most intellectual of mankind, and to furnish inexhaustible materials for study to the naturalist, and for speculation to the philosopher.' See A. R. Wallace, *Malay Archipelago* (vol. ii. 1869); Elliot, *Monograph of Paradiseidae* (1873).

Bird's-eye Limestone (so called from the crystalline points disseminated through the rock) is a division of the Trenton group of the Lower Silurian of North America, apparently equivalent to the Llandeilo flags, and containing, besides the remains of brachiopods, many enormous orthoceratites.

Bird's-eye View is a term applied generally to modes of perspective in which the eye is supposed to look down upon the objects from a considerable height. In sketching or drawing a locality for military or economical purposes, this kind of perspective is always used. The great difficulty is to represent at the same time the relative heights of mountains and steepness of acclivities. But the more usual kind of bird's-eye view differs from the common perspective picture only in the greater height of the horizontal line.

Bird's-foot (*Ornithopus*), a genus of Leguminosae, sub-order Papilionaceae, deriving both its popular and its botanical name from the resemblance of the curved pods to birds' claws; the leaves are pinnate, with a terminal leaflet. The Common Bird's-foot (*O. perpusillus*) grows on dry sandy or gravelly soils, and is a small plant of little importance, although eagerly eaten by sheep. But *O. sativus*, an annual growing to the height of 2 or 3 feet, a native of Portugal, is cultivated in that country as green food for cattle, and is very succulent and nutritious. Like its British congener, it grows well on very poor soils. Its Portuguese name is Serradilla.

Bird's-foot Trefoil (*Lotus*), a genus of Leguminosae, sub-order Papilionaceae. The English name is derived from the resemblance of the clusters of pods to a bird's foot. The common species (*L. corniculatus*) is very abundant everywhere in Britain in pastures. It has a stem 6 to 12 inches in length, decumbent, and bearing umbellate heads of 8 to 10 yellow flowers, which have a rich honey-like smell. The plant has been sometimes regarded as

Bird's-foot Trefoil.

the Shamrock (q.v.) of Ireland. It is eaten with great avidity by cattle, and its deeply penetrating roots adapt it well for very dry situations.—A

larger species, otherwise very similar, with stem nearly erect, more compact heads of smaller flowers, and smaller seeds, is the Greater or Narrow-leaved Bird's-foot Trefoil (*L. major*), which also is a common native of Britain, generally found in moist, bushy places. The Winged Pea (*L. Tetragonolobus*), often separated as the type of a distinct genus on account of its quadrangular winged pods, is a native of the south of Europe, and was formerly cultivated in Sicily and Spain as an esculent; it is sometimes sown as an annual in flower-borders in Britain.

Bird's-nest is a name applied to two or more distinct plants, of similarly brownish colour and leafless habit, which are root-parasites, and grow more or less concealed under other vegetation. *Neottia* (*Listera*) *Nidus-avis*, the bird's-nest orchis, grows in dark woods, especially beech; *Monotropa Hypopitys*, a rare ericaceous plant, also grows in beech or fir woods. There is also a bird's-nest fern (*Asplenium Nidus*); and a group of Gasteromycete fungi, the *Nidulariei* (*Cyathus*, *Nidularia*), from their cup-shape and egg-like spore-bearing masses, have also acquired the same popular name.

Birds of Prey, an order of Birds also known by the more technical names of *Accipitres* and *Raptores*. Vultures, eagles, hawks, falcons, and owls are familiar examples. The division belongs to an old classification, based as the terms suggest on likenesses of habit rather than similarities of structure. Unlike some of the other old orders, however, the birds of prey form a well-defined series, and correspond to the group *Actomorphæ* in Huxley's anatomical classification. They feed for the most part on warm-blooded animals, which they catch alive and tear to pieces. They are in almost every respect exceedingly highly developed birds. Their senses are very acute, their flight strong and rapid, their size and strength above the average. The beak is very strong and sharp, the upper part slightly overhangs the lower, the margins are well adapted for cutting. The toes are armed with strong bent claws, and the feathers come down to the angle of the foot. The females usually do all the brooding, but the males keep up the food-supply for the young. Their nests are lofty. The distribution is very wide. Three families—Owls, Vultures, and Falcons—are commonly distinguished. See the separate articles.

Biretta (Ital. *berretta*; dim. of *birrus*, 'a hooded cloak'), a square cap worn by the clergy of the Roman Catholic Church, and by some ritualists in the Anglican Church. That of priests is black, of bishops purple, of cardinals red. Originally round, its present form, with straight, erect edges, and a tuft or button on the crown, dates only from the 17th century; but the low head-covering of English bishops was known as the *birettum* as early as the 13th century.

Biretta.

Birkbeck, GEORGE, M.D., distinguished for the leading part he took in founding mechanics' institutions and in the education of the working-classes, was born at Settle, in Yorkshire, in 1776.

He commenced his medical studies at Leeds, and pursued them at Edinburgh, where he made the acquaintance, among others, of Sydney Smith, Brougham, Jeffrey, and Horner. Appointed in 1799 to the chair of Natural Philosophy in the Andersonian Institution in Glasgow, he delivered his first free course of lectures to the working-classes in the following year. He took a leading part, along with Brougham, Bentham, Cobbett, and others, in the formation of the London Mechanics' Institute (1824)—the first of its kind in the kingdom. He was chosen its president for life, and it is called the Birkbeck Institution after him. In 1883-84 it was rebuilt on an adjoining site. Birkbeck died in London, 1st December 1841. See the Life by Godard (1884), and the article MECHANICS' INSTITUTES.

Birkenfeld, a German principality belonging to Oldenburg, but surrounded by the Prussian Rhine province, and intersected by the railway from Bingen to Saarbrück. It has an area of nearly 200 sq. m., with a population of 41,242; it has been connected with Oldenburg, 300 miles distant, since 1817. The capital, Birkenfeld, has a pop. of 2500.

Birkenhead, a market-town, seaport, and municipal and parliamentary borough of Cheshire, lies opposite Liverpool, on the left bank of the Mersey. Birkenhead owes its origin to the Benedictine Priory of *Byrkhed*, founded in the 11th century. Edward II. granted the monopoly of the ferries to its monks. The crypt and other portions of the priory still remain. Birkenhead has within the last few years risen from comparative obscurity to its present important position. No later than 1818 only a few straggling houses existed, and the population numbered 50. In 1821 it amounted only to 236. In 1836 it received the grant of a market, in 1861 obtained the privilege of returning a member to parliament, and in August 1877 was created a municipal borough. Besides the township of Birkenhead, the borough includes Cloughton, Oxtan Trammere, Rock Ferry, and part of Higher Bebington. The principal streets of Birkenhead are laid out with great regularity, crossing each other at right angles, and about 20 yards wide; but the back streets are narrow and the houses mean. One of the features of Birkenhead is the park, 180 acres in extent, laid out at a cost of £140,000. There is another park in Trammere, called Mersey Park, of 29 acres and £33,000 cost, opened July 1885. The principal public buildings are the market-hall, the new town-hall, the new sessions and police courts, the borough hospital, the free library, and the public baths. A railway bridge over the Mersey at Run-corn, opened for traffic in 1869, shortened by 10 miles the distance between the Liverpool and Birkenhead docks; and the Mersey railway tunnel, 1230 yards long, was opened by the Prince of Wales on January 20, 1886. There is also communication with Liverpool by ferry-steamers. The idea of constructing docks at Birkenhead is due to the great firm of Laird & Son, who in 1824 purchased from the Liverpool corporation, at a very low price, a large piece of ground on the borders of the Wallasey Pool. It was not, however, till 1847 that the first dock constructed by the Birkenhead Dock Company was opened. In 1857 the docks at Birkenhead were amalgamated with those of Liverpool, and vested in one public trust, called 'The Mersey Docks and Harbour Board.' Including the Great Float, an immense harbour, constructed on the site of Wallasey Pool, with an area of over 140 acres, they extend from Woodside to Seacombe, a distance of about a mile, the total area being about 170 acres, with 9½ miles of quays. The Birkenhead docks are not in themselves remunerative. The corn-

warehouses at Seacombe constitute an immense pile of buildings, and a great deal of coal is shipped from the port.

Birkenhead has for some years been celebrated for its shipbuilding yards, some of the largest iron ships afloat having been built there by extensive firms. The too historical *Alabama* was built by the Messrs Laird, to whose enterprise, more than that of any other company, the town owes its present eminence. In the neighbourhood of the docks are the Canada Works for the construction of gigantic bridges, the Britannia Machinery Works, the Birkenhead Forge, and Messrs Cochran & Co.'s engineering and shipbuilding works. There are also oil-cake mills, extensive flour-mills, wagon-works, and several smaller engineering works. St Aidan's College, an Anglican theological college, is in the suburb of Clughton. Pop. (1871) 65,971; (1881) 84,006; (1891) 99,857.

Birket-el-Hadji ('lake of the pilgrims'), a small lake 10 miles N.E. of Cairo, where the Mecca pilgrims assemble and separate.

Birmah. See *BURMA*.

Birmingham, a municipal, parliamentary, and county borough (whose chief magistrate is since 1893 styled Lord Mayor), is the chief town of the Midlands, celebrated for its metallic manufactures, and boasts to be the 'best governed city in the world.' It stands near the centre of England, in the north-west of Warwickshire, with suburbs extending into Staffordshire and Worcestershire, 112½ miles N.W. of London. The name appears in *Domesday* as *Berningeham*. On the attainder of Edward de Bermingham in 1527, it came into the possession of Dudley, Duke of Northumberland, and on the latter's attainder passed to the crown. During the Civil War the town supplied the Parliamentarians with swords, but it was taken by Prince Rupert in 1643. It suffered severely from the plague in 1665-66. The celebration by a number of Radicals, 14th July 1791, of the capture of the Bastille, was the occasion of a serious riot by the upholders of church and king, who attacked the house of the Unitarian minister, Dr Priestley, and destroyed his library. Subsequently it was prominently associated with the Chartist agitators, and within recent years it was the headquarters of what was known as the Liberal 'caucus.' It is picturesquely situated on the east slope of three undulating hills, on the Lea and the Tame, on a gravelly foundation over-lying clay and new red sandstone, and though rather irregularly built, with many narrow and winding streets, has been greatly improved in this respect within recent years, while its water-supply and sanitary arrangements are of the most satisfactory kind. Owing to its rapid growth the town is badly supplied with open spaces and recreation grounds in the central districts, but there are seven public parks, all situated in the suburbs. It possesses a large number of fine public buildings, among which may be mentioned the town-hall (1832-52), in the Corinthian style, erected at a cost of £50,000, the scene of the triennial musical festivals and the great political meetings for which the town is famous; the market-hall (1838); the municipal buildings (1874-78), in the Italian style, erected at a cost of nearly £200,000; the corn exchange (1847); the exchange buildings (1863-65), in the Gothic style; and the post-office. The water-works, originally established by a company in 1854 at a cost of £300,000, are now owned by the corporation.

The benevolent or reformatory institutions include the borough gaol, the lunatic asylum, and the general and Queen's hospitals. No town is better supplied with institutions for the promotion of education and the development of the arts and

sciences. These include Queen's College, incorporated by act of parliament in 1867, for the study of theology and medicine; the Mason Science College, the Birmingham and Midland Institute, the corporation museum and art gallery, the new school of art, the old library, the free library, King Edward VI.'s grammar-schools (entirely remodelled in 1878), and the blue-coat school. The Mason Science College was founded by Sir Josiah Mason, February 23, 1875, and was opened October 1, 1880. Its object is to promote 'thorough systematic education and instruction, specially adapted to the practical, mechanical, and artistic requirements of the manufactures and industrial pursuits of the Midland district, and particularly the boroughs of Birmingham and Kidderminster, to the exclusion of mere literary education and instruction, and of all teaching of theology, and of subjects purely theological.' Examinations for degrees in arts, science, and medicine, and for honours, exhibitions, and scholarships, conferred by the university of London, take place annually. The foundation of King Edward VI. consists of one high school for boys and one for girls in the centre of the town, together with boys' grammar-schools and girls' grammar-schools in various parts of the town. Elementary education is fully provided for, and Mr Dixon's generosity enabled the School Board to establish a technical school. A modern university on large lines was projected in 1899, to absorb Mason University College; a draft charter was submitted to the Privy Council; and an endowment of over half a million was secured. See the articles on Priestley, Chartism, Bright, J. A. James, J. H. Newman, Chamberlain, &c.

Statues or memorials have been erected to Nelson (1809), Sir Robert Peel (1855), Thomas Attwood (1859), Joseph Sturge (1862), James Watt (1868); Prince Consort (1868), Dr Priestley (1873), Right Hon. Joseph Chamberlain, M.P. (1880), J. S. Wright (1883), Queen Victoria (1884), George Dawson (1885), Barnaby (1885), Sir Josiah Mason (1886), and John Bright (1892). Of the ecclesiastical buildings it must suffice to mention the parish church of St Martins, erected in 1873 at a cost of nearly £30,000, on the site of the old building, dating from the 13th century; and the Catholic cathedral of St Chad (Birmingham being the seat of a Catholic see), erected from the designs of Pugin, at a cost of over £30,000.

In Leland's *Itinerary* (1538) Birmingham is referred to as the abode of 'smiths and cutlers.' In cutlery goods it has been completely superseded by Sheffield, but in all other kinds of the finer metal manufactures it is unrivalled by any other town in the world. Iron and brass founding are carried on, and steam-engines and various kinds of machinery are made; but the principal manufactures are the finer kinds of gold, silver, copper, brass, steel, mixed metal, plated metal, glass, papier-maché, japanned and electrotyped articles, including fire-arms, ammunition, swords, metal ornaments, toys, jewelry, coins, buttons, buckles, lamps, pins, steel-pens, tools, arms, and locks. Over 560,000 gun-barrels were manufactured in 1891; and other specialities, of which an enormous quantity are manufactured, are steel-pens, buttons, nails, and screws. The term *Brummagem*, an old name for Birmingham, is colloquially used to denote anything sham or fictitious, such as cheap jewelry, which is largely made here. Near Handsworth, a little to the north of Birmingham, were the famous Soho Works, founded by Watt and Boulton, where steam-engines were first made. Handsworth Church has a statue of Watt by Chantrey, and a bust of Boulton by Flaxman.

Baskerville, the printer, carried on his business

in Birmingham; Hutton, the antiquary, author of the *History of Birmingham*, was a bookseller in the town. Wilmore and Pye, the engravers, and David Cox, the landscape-painter, were Birmingham men. Thomas Attwood originated the Political Union here, which greatly hastened the passing of the Reform Act of 1832, and the enfranchisement of Birmingham. Dr Joseph Priestley, natural philosopher and metaphysician, was for some time Unitarian minister in Birmingham, as was also the brilliant lecturer George Dawson. Birmingham has been remarkable in recent times for its 'school of politics.' Its leading principle may be justly described as 'government by the people for the people.' Birmingham was incorporated 31st October 1838, and on 26th June 1884 was constituted an assize town. In 1867 the number of parliamentary representatives was increased from two to three, and in 1885 it was divided into seven parliamentary districts, each returning one member. A resolution was agreed upon by the town council in January 1888, for enlarging the town boundaries, so as to include the suburban districts. The population in 1770 was 30,806, which by 1801 had increased to 60,822, by 1851 to 232,841, by 1871 to 343,787, and by 1881 to 400,774. A county borough since 1888, it had in 1891 a pop. of 478,113. See Hutton's *History of Birmingham* (1781); Langford's *Century of Birmingham Life* (1868); and Dent's *Old and New Birmingham* (1879-80) and *The Making of Birmingham* (1892).

Birmingham, the capital of Jefferson county, Alabama, and the most important seat of the iron industry of the southern states, is situated at the junction of several railways, 95 miles NNW. of Montgomery, with numerous foundries, mills, factories, and machine-shops. The development of the iron interests of its immediate vicinity has caused a marvellous growth of the city. In 1880 its population was scarcely more than 3000, and its land of little value. In 1890 the aggregate value of its property was estimated at over £5,000,000, and its population was 26,178.

Birnam, a Perthshire hill 1324 feet high, near Dunkeld, commanding a splendid view of the valley of the Tay. Birnam Wood, forming part of an ancient royal forest, is immortalised by Shakespeare in *Macbeth*. Opposite Dunkeld is the pretty village of Birnam, the summer residence of Sir J. E. Millais.

Birni, a town of Bornu, Central Africa, about 100 miles W. of Lake Tsad, formerly the capital, but now almost completely in ruins. Its place has been taken by Kuka, close to the lake, with a pop. of about 60,000.

Biron, the title of a family that has given several marshals to France. The most distinguished of these are: (1) ARMAND DE GONTAUT, BARON DE, born in 1524, fought against the Huguenots at Saint-Denis and Moncontour, but early joined and rendered great service to Henry IV. He was killed at the siege of Epemay in 1592. His *Correspondance* was edited by Barthélemy in 1874. —(2) CHARLES DE GONTAUT, DUC DE, son of the preceding, was born in 1562. His intrepid valour gained him the affection of Henry IV., and the nickname of 'Fulmen Gallie;' but being convicted of a treasonable correspondence with Spain, he was beheaded in the Bastille in 1602. —(3) ARMAND LOUIS DE GONTAUT, DUC DE, born in 1753, fought with Lafayette in America, joined the Revolutionists in France, for whom he commanded several armies, and defeated the Vendéans at Parthenay in 1793. Accused, however, of oppression and falsehood by two fellow-generals, he was guillotined, 1st January 1794. His *Mémoires* (new ed. by Lacour, 1858) are valuable.

Biron, ERNEST JOHN DE, Duke of Courland, born in 1690, was the son of a landed proprietor in Courland, of the name of Bühren. His person and intellect gained him the favour of Anna Ivanovna, niece of Peter the Great, and, when she ascended the throne of Russia in 1730, Biron was loaded with honour. He assumed the name and arms of the French dukes De Biron, and soon swayed all Russia through his royal mistress. Proud and despotic by nature, he hated every one who stood in the way of his ambition. More than a thousand persons were executed by his orders, and a far greater number sent into banishment: still by the strength of his character he introduced vigour and power into every branch of the public administration. On the death of the empress (28th October 1740), Biron assumed the regency, and acted with great prudence and moderation. A secret conspiracy was, however, soon formed against him, and three weeks after, he was arrested, and, along with his family, conveyed to Siberia. On Elizabeth's accession in the following year, he was recalled, and spent the remainder of his life in retirement. He died in 1772.

Birr. See PARSONSTOWN.

Birs, a small Swiss stream which enters the Rhine near Basel. Its banks were the scene of two battles in the 15th century, in one of which 500 confederate Swiss died heroically, in 1444, in battle against the French; in the other, 6000 of their countrymen gained a splendid victory over 15,000 Austrians in 1499.

Birs-Nimroud. See BABEL.

Birth is generally applied to the delivery of a living child, and not to the mere expulsion of an ovum, or fetus, or dead child. Numerous medico-legal questions of importance may arise regarding the real or supposed birth of a child. Only a few points regarding the most common of these can be touched on here. (a) Has the supposed mother been delivered of a child? Was it at or about the time alleged? The fact of delivery is often concealed, sometimes it is falsely assumed. It is only for about eight or ten days after birth that, in the case of a healthy woman, physicians can tell certainly whether or not delivery has just taken place. It is however generally possible to say whether or not a woman has had a child at some time or other; so that delivery which is feigned for the purpose of extorting charity, compelling marriage, or disinheriting other parties, can generally be detected by medical jurists. (b) Was the child mature when born? or sufficiently developed for it to live? A child reaches maturity about nine months after conception, when the head is covered with hair, and the finger nails are completely formed; the average length is 18 inches, and weight between 6 and 7 lb.; but wide deviations from these figures are met with. It is very rare for a child to live more than a few hours if born before the end of the seventh month from conception. (c) Was the child born alive? how long did it survive its birth? (see INFANTICIDE). With regard to questions of inheritance, a child is considered capable of taking and transmitting property, if it has lived for an instant, although it may not have cried or moved. See ABORTION, BASTARD, HEIR, ILLEGITIMACY, INFANTICIDE, LEGITIMATION, REPRODUCTION; for Birthright, see FAMILY, FIRST-BORN, FEUDALISM, SUCCESSION; and for Registration of Births, see REGISTRATION.

CONCEALMENT OF BIRTH is a criminal offence in the law of all civilised countries. In England, under the Criminal Law Consolidation Act of 1861, every person who endeavours to conceal a birth by a secret disposition of the dead body of the child

is liable to be imprisoned, with or without hard labour, for any term not more than two years; it is not necessary to prove whether the child died before, at, or after its birth. This law does not apply to the case of a woman being delivered of a foetus (see ABORTION). Concealment includes the case of the body being laid down in an unfrequented place though not hidden. Many cases dealt with are undoubtedly cases of murder through exposure. Accordingly, a verdict of concealment can be returned on an indictment charging murder.

In Scotland, from 1690 till 1803, concealment of birth was construed as presumptive of child-murder, and punished with death, in all cases where a woman concealed her being with child during the whole period of her pregnancy; where she did not call for, or make use of help or assistance in the birth; and where the child was found dead, or was amissing. The case of Tibby Walker (the 'Effie Deans' of Scott's *Heart of Midlothian*) is a familiar instance. The capital penalty was first superseded by banishment; and now, by a statute of 1809, the woman is liable to imprisonment for a period not exceeding two years. Of course, this law does not apply to cases of premature birth, at least where the offspring cannot properly be called a child. In both England and Scotland, the law is dictated by a desire not to press charges of murder against unfortunate women. In England, only the secret disposal of the body is punished, and for this the paramour is often responsible. In Scotland, if the child were born alive and shown to any one, no conviction could be obtained. It has been decided that disclosure by the mother to the putative father, or even conduct implying disclosure, or confession before a kirk-session, is a sufficient defence. The punishment usually awarded for this offence in Scotland is imprisonment from three to six, and in aggravated cases, from nine to eighteen months. See INFANTICIDE.

BIRTH. REGISTRATION OF. See REGISTRATION.

Birthday Books. These had their origin by the issue in 1866 of the *Birthday Scripture Text-book* by Mr W. Mack, bookseller, Bristol, who was also its joint-compiler. The success of the idea was immediate, and up till 1888 about a million copies of this book alone had been sold, in various sizes, besides the sale of about half a million of other kinds issued by him at a later date. His plan, which was soon widely imitated by other publishers, was to issue a daily Scripture text-book, and so to interleave it that there should be opposite each day sufficient space for the autographs of several friends. It thus served the double purpose of a reminder of the birthdays of friends and an autograph-book. A Shakespeare birthday book followed, and soon all the chief poets and prose-writers were laid under contribution for this purpose. The idea was extended to include illustrations, and the Princess Beatrice furnished fifteen water-colour designs for a birthday book, which were reproduced by chromo-lithography.

Birthwort. See ARISTOLOCHIA.

Biru, a kingdom of Soudan, Western Africa, bounded on the E. by the Niger. The capital is Walata.

Bisac'cia, a town of Italy, 60 miles E. of Naples. Pop. 6189.

Bisacquino, a town of Sicily, 27 miles S. of Palermo. Agate and jasper are found in the neighbourhood. Pop. 9588.

Bisalnagar, or VĪSNAGAR, a town of Baroda, in Bombay Presidency, 220 miles NW. of Mhow. It has a large transit-trade, and manufactures cotton cloth and copper vessels. Pop. 21,376.

Bisalpur, a town of India, in the North-west Provinces, 24 miles E. of Bareilly. Pop. 8903.

Biscacha. See VISCACHA.

Bis'cay, or VIZCAYA, the most northerly of the Basque Provinces of Spain, is bounded N. by the Bay of Biscay, E. and S. by its sister-provinces, Guipuzcoa and Alava, and W. by Santander (see BASQUES, FUERO). It has an area (very mountainous in the south) of 849 sq. m., and a population of 235,659. Chief town, Bilbao (q.v.).

Biscay, BAY OF (Fr. *Golfe de Gascogne*), that portion of the Atlantic Ocean which sweeps in along the northern shores of the Spanish peninsula in an almost straight line from Cape Ortegal to St Jean de Luz, at the western foot of the Pyrénées, and thence curves northward along the west shores of France to the island of Ushant. Its extreme width is about 400 miles, and its length much about the same. The depth of water varies from 20 to 200 fathoms, being greatest along the north shores of Spain. The whole of the south coast is bold and rocky, and great parts of the French shores are low and sandy. The bay receives numerous unimportant streams from the mountains of Spain, and, through the rivers Loire, Charente, Gironde, and Adour, the waters of half the surface of France. Its chief ports are Santander, Bilbao, and San Sebastian, in Spain; and Bayonne, Bordeaux, Rochefort, La Rochelle, and Nantes, in France. Navigation of 'the bay' is proverbially trying to inexperienced voyagers, and is frequently rendered dangerous by the prevalence of strong winds, especially westerly ones. Rennel's Current sweeps in from the ocean round the north coast of Spain.

Bisceglie, a seaport town of Italy, on the Adriatic, 21 miles NW. by W. from Bari. Bisceglie has a cathedral (dating from the 12th century), besides several other churches, a seminary, a hospital, &c. The neighbourhood produces good wine and oil. Pop. 21,675.

Bischof, KARL GUSTAV, a distinguished chemist and geologist, born near Nuremberg in 1792, in 1822 became professor of Chemistry in Bonn, where he died 30th November 1870. His writings include technical treatises on botany, chemistry, and geology, the chief being a Manual of Chemical and Physical Geology. Between 1837 and 1840 he began a series of important experiments on inflammable gases in coal-mines, and on safety-lamps.

Bischoff, MOUNT, a post-town of Tasmania, 60 miles W. of Launceston, which owes its existence to the discovery here in 1872, by Mr James Smith, of some of the richest tin mines in the world. Between 1884-86 more than 20,000 tons of tin ore had been raised. The yield of pure tin from the ore is from 70 to 80 per cent. The mount takes its name from the chairman of a land company (1828). There is railway communication with Emu Bay, 45 miles distant. Pop. of mining locality, over 2000.

Bischoff, THEODOR LUDWIG WILHELM, an eminent anatomist and physiologist, and more especially embryologist, was born at Hanover, 28th October 1807. He studied at Bonn and Heidelberg, becoming in 1836 extraordinary professor, and in 1843 ordinary professor of Anatomy and Physiology at Heidelberg. From 1844 to 1855 he filled the same chair at Giessen, where he founded a physiological institute and anatomical theatre, and from 1855 to 1878 at Munich. In the latter year he retired, and he died at Munich, 5th December 1882. Bischoff devoted his studies mainly to embryology and biology, and has left numerous treatises and papers of great value.

Bischweiler, a German town of Alsace, on the Moder, 17 miles N. of Strasburg. Its fortifications were dismantled in 1706. It has manufactures of jute, cloth, carpets, and cartridge-cases, and raises hops. Pop. 7014.

Biscuit, in Pottery, is the name given to porcelain and other pottery after the first firing. See POTTERY.

Biscuits (Fr., 'twice-baked'), small, flat bread, rendered dry and hard by baking, in order to their long preservation. Biscuit-baking is rapidly becoming an industry in itself, and factories are rising up all over the country where biscuits are made in large quantities. In these factories the flour and other ingredients of which biscuits are made is never handled from the time it enters the works until it issues from them as a finished article. In the case of hard biscuits the various ingredients are run into a kneading-machine, where they are thoroughly incorporated into a stiff dough. This is then 'braked'—i.e. passed and repassed between rollers until pressed into long sheets with smooth surfaces. These sheets are then placed on a biscuit-cutting machine, which is provided with a pair of rollers set to compress the dough as it passes between them into the desired thickness. The dough is carried along by a woollen or canvas web, which delivers the dough underneath a block containing cutters which descend and cut the biscuits to the desired shape. As the block rises, the web carries the cut dough onwards, the scrap dough being collected; they next pass on to a wire frame travelling through a heated chamber or oven. The passage through the oven occupies about fifteen minutes, during which time they are completely baked. They are then carried to the packing-room, and when cool at once packed in tins. So rapidly is this operation conducted, that about 2000 lb. weight of biscuits are passed through one of these ovens every day of ten hours.

Biscuits are divided into two classes—the *unfermented* and the *fermented*. *Unfermented* or *unleavened* bread, generally known as *common sea-biscuits* or *ship-bread*, are made of wheaten-flour (retaining some of the bran), water, and common salt.

Captains' biscuits are prepared from wheaten-flour, water, with common salt, and butter, with an occasional small dose of yeast to cause partial fermentation. Milk is also sometimes employed. *Water biscuits* are made of flour and water; *hard biscuits*, of flour and water, with variable quantities of butter, spices, and sugar. *Soft biscuits* contain increased quantities of butter and sugar. *Yeast biscuits* are those the dough of which is mixed with a small quantity of yeast, yielding more porous biscuits. *Butter biscuits* are made with much butter and a little yeast.

In making fancy biscuits great care must be taken in the manipulative part of the process to incorporate the ingredients in a systematic manner. Thus, the butter is mixed with the flour in a dry condition, and then the water or milk added; and when eggs are used, they are thoroughly beaten up with the sugar (if the latter is required), and the egg-paste added to the dough, which has been previously prepared with or without butter. The various kinds of biscuits in the preparation of which yeast is employed, present a more spongy aspect than the unyeasted biscuits. Occasionally a little sesquicarbonate of ammonia (volatile salt) is added, to assist in raising the dough, and make a lighter biscuit. A great objection, however, to fermented biscuits is that they deteriorate very rapidly on keeping.

Soft or *speed biscuits* are prepared from flour, with much sugar, a great many eggs, some butter, and a

small quantity of spices and essences. The eggs tend to give a nice yellow cream-colour to the biscuits.

The extent to which biscuits are now consumed may be learned from the fact that several of the largest biscuit-manufactories each prepare and throw into market every week from 30,000 to 50,000 lb. weight of biscuits of various kinds.

Of biscuits requiring special methods of manufacture, we may mention 'meat biscuits,' 'digestive biscuits,' 'charcoal biscuits,' and what is known as the 'perfect food biscuit.' The *meat biscuit* has not met with much favour as an article of food. It consisted of the usual ingredients of hard biscuit made up with a soup containing the soluble matters of beef. One of the objects of the meat biscuit—viz. the preservation of animal food of South America and Australia, has been attained by other preferable methods (see PRESERVED PROVISIONS). A coarse kind of meat biscuit is used for feeding dogs.

Digestive biscuits are prepared in such a manner that they may contain diastase, the nitrogenous transforming matter of malt; but whatever quantity of this substance they may contain in the condition of dough is destroyed in the process of baking.

Charcoal biscuits, originally introduced by Bragg, were once held in great repute as a kind of medicinal food. They contain wood charcoal incorporated in their substance. The wood charcoal usually acts as an absorbent of gases, but it loses this quality when saturated with moisture; and it is in this condition, of course, that it reaches the stomach, any benefit that may accrue therefore from the use of charcoal biscuits cannot be due to its absorbent powers. It may, however, be of some benefit by acting as a mild mechanical irritant.

The *perfect food biscuit*, invented by S. Henderson & Sons, is one whose composition is based on the proportion of chemical elements needed for a complete and perfect dietary—i.e. it is designed to contain all the food materials, and in the proper proportion, that physiology indicates as required for the nourishment and support of the human body.

Bish, BISHMA, or BIKH. See ACONITE.

Bishop. The word comes to us from the Anglo-Saxon *biscop*, an abbreviated form of the Greek *episcopos*—i.e. 'overseer.' In classical writers, from Homer downwards, it signifies an inspector or superintendent of any kind, though they also use it as a title of various officers with special and determinate functions—e.g. of commissioners sent by the Athenians to regulate the affairs of colonies and subject states, and of magistrates who superintended the sale of provisions in the market under the Roman empire. In the Septuagint the usage of the word corresponds, on the whole, to that in classical writers. Sometimes the sense is quite general, as when, for instance, in Job, xx. 29, it occurs as a name for God who watches over the conduct of men; but usually it denotes officers intrusted with the superintendence of some particular work, whether civil or religious. Had the history of the word ended here, it would never have come, as it actually has done, to form part and parcel of every language spoken by Christians of the East and West. It appears in Syriac and Arabic, in Spanish and German, and everywhere, even in the French *évêque*, the original Greek form may be recognised. While, however, the word itself has been retained, the sense attached to it has undergone a radical alteration. Throughout the New Testament *episcopos* is interchangeable with *presbyter*; both are synonymous titles of officers who direct the discipline and administer the affairs of a single congregation, but, from the latter part of the 2d century, it has assumed a widely different meaning, which it still retains. Instead of being synonymous

with presbyter, it implies superiority over a body of presbyters; instead of superintendence in a particular congregation, it suggests rule over a number of congregations united in a diocese. It has ceased to mark an office which may be held by many in the same place, and has been appropriated to one who is supreme over presbyters and laity within the confines of a diocese. A modern bishop occupies a position in his diocese which is unique. He alone ordains presbyters and consecrates churches. He exercises authority over clergy and laity alike. To him the duty of preaching and instructing, and of maintaining sound doctrine, is specially committed. A New Testament bishop or presbyter was the member of a council which watched over the government of a congregation. So far we are on secure ground. The proofs of the alterations which have affected the meaning of the term will be given further on. Meantime, it is enough to say that the fact is admitted by competent persons of every theological school, even by Roman Catholics, such as Dollinger, *First Age of the Church* (Eng. trans. p. 286), and is treated as probable by Estius on Philipians, and Petavius, *Ecclesiast. Hierarch.* lib. iv. cap. 2. 'The orders,' says Thomas Aquinas (on Philipians), 'were distinct, but not the names of the orders.'

The matter is indeed very different when we pass from the word 'bishop' to the history of the episcopal office. Thus, while the more learned Roman Catholics admit that the words 'bishop' and 'presbyter' are synonymous in the New Testament, they also allege that modern bishops are by divine right superior to presbyters, and are the successors, not of those who bear the same name in the New Testament, but of the apostles. The Council of Trent anathematizes those who deny that bishops are superior to presbyters, or assert that the episcopal power of ordination is common to the latter (Sess. xxiii. can. 7). True, Roman Catholic divines make some distinction between bishops and apostles, whose successors they are said to be. It is admitted that the apostles had jurisdiction throughout the world, whereas the bishop's power is restrained to a particular diocese. But the bishop, like the apostle, ordains priests, rules over them and over the laity, and this by divine and unalterable institution. The position of High Church Anglicans is much the same. They consider episcopacy as necessary, not only to the well-being, but to the being of a church. To Anglicans of the more moderate school, episcopacy is a venerable form of church government which descends from apostolic times, but they do not count it an essential matter, and they have no mind to unchurch the Protestant communities which have been formed on another model. Presbyterians, on the other hand, contend that the government of the church by presbyters has, and has alone, the sanction of the New Testament, and they reject modern episcopacy as a corruption of primitive Christianity. But at all times the Protestant churches, whether Episcopalian, or Presbyterian, or Congregationalist, have had men among them who could adopt none of these positions; who believed that the free spirit of Christianity inculcates no definite form of church government, and have regarded the varying shapes which it has assumed as things indifferent in themselves, good or bad according to circumstances, never so good as to compensate in any degree for the absence of spiritual life, never so bad as to preclude its existence. And just as there have been men who forgot disputes about church government in the interests of the spiritual life, so there have been in England, and still more in Germany, scholars who have investigated the history of episcopal power with a learning and impartiality which

is not to be found in the war of the churches. We may say, briefly, that the result of all real investigation has been to show how utterly unlike the state of the earliest churches was to anything which either exists or could be reasonably desired at the present day. An attempt will be made here to state and to arrange the facts without entering into sectarian controversy. It must be premised that the whole tradition of the church, from the close of the 2d century onwards, tells, on a *prima facie* view, for the Roman Catholic and High Church theory of apostolical succession. Each cause has enlisted consummate learning on its side. But the method chosen here has at least the advantages that it is less familiar to the mass of English readers, that it has commended itself to scholars even within the pale of episcopal communions, and that it enables us to exhibit, without prejudice to any theory, the data by which all theory must be tested and proved.

Our earliest and surest sources of information are the undisputed epistles of St Paul, and there it is significant that the word 'bishop' occurs once only, and that in the latest of his epistles (Philip. i. 1). But in one important passage the apostle makes a formal enumeration of the different positions or grades occupied by the members of the church. We use of set purpose language which is vague, because, as we shall see presently, the powers indicated are vague, at least so far as the government of the church is concerned. 'God,' he says, 'hath set some in the church, first apostles, secondly prophets, thirdly teachers, then miracles, then gifts of healing, helps, governments, divers kinds of tongues' (1 Cor. xii. 28). It will be observed that he speaks of divine appointment, not of popular choice, and the reason is plain, for 'powers,' 'gifts of healing,' 'tongues,' 'prophecy,' were obviously miraculous gifts, and the same holds good, though perhaps in a lower degree, even of teaching, as appears from 1 Cor. xiv. 26; while Paul himself is a conspicuous example of an apostle, sent neither from men nor through human instrumentality, but by God 'through revelation of Jesus Christ' (Gal. i. 1-17).

Still the question remains whether the apostolic included the later episcopal office, and to this question diverse answers are given. Roman Catholics and many Anglicans reply in the affirmative. Presbyterians and many independent scholars also urge that there is scarcely a single feature common to the two. It is only, they plead, in the teeth of history that the distinction can be reduced to one between universal and local jurisdiction. The apostles had no universal jurisdiction; and their nearest counterpart, though even that is wide of the mark, is to be found in the modern missionary. The name of 'apostle,' which occurs once only in Matthew (x. 2), and once in Mark (vi. 30), oftener in Luke, was first given to the twelve. They were sent to the twelve tribes of Israel, and they continued this work, after the death of Jesus, in Jerusalem, and then throughout Judæa. The same name was taken by Paul after he 'had seen the Lord.' Among the Jewish congregations it was extended to James, the Lord's brother (Gal. i. 19), who had seen the risen Christ (1 Cor. xv. 7), and no doubt at a very early date to others, for Paul distinguishes 'all the apostles' as a larger class from the restricted number of the twelve. In the churches beyond Judæa, Timothy and Silvanus (1 Thess. i. 1, ii. 6), Barnabas (1 Cor. ix. 5), Apollos (1 Cor. iv. 6-9), Andronicus, and Junias (Romans, xvi. 7), were all apostles. Certain conditions seem to have been required before a man was generally recognised by this title. He must have

seen the Lord (1 Cor. ix. 1), approved himself by signs (2 Cor. xii. 12) and visions (2 Cor. xii. 1). The appointment, then, of an apostle, and the qualifications according to this view were wholly different from the appointment and qualifications of a bishop. No less different are the powers in the one case and the other. The bishop is the supreme administrator within the diocese in which he is nominated, being invested therein with supreme disciplinary authority. An apostle had no authority except over churches which he had founded. Paul, believing in the truth of his gospel, was ready to proclaim it to all, but the position he adopts to the Romans is quite other than that which he adopts to churches which owed their faith to him. He will not build 'on another man's foundation;' if he hopes to impart some spiritual gift to the Romans, he adds that the benefit will be mutual (Romans, i. 12), and he almost apologises for writing to them at all (Romans, xv. 15). It was his converts who were the seal of his apostleship (1 Cor. ix. 2). Even within his own sphere there is scarcely a resemblance between the authority of an apostle and a bishop. That of the former is much greater and much less, much greater in moral influence, much less in legislative authority. Paul's rights over his converts were those of a father who had begotten them in the gospel (1 Cor. iv. 15; Gal. iv. 19): it was his duty to remind them of the gospel they had received, accompanied and attested by the gifts of the Spirit, and to admonish them in case they were unfaithful to it (1 Cor. iv. 18-21, xiv. 37; 2 Cor. xiii. 2). When he has a distinct command of the Lord, he lays down an absolute precept. 'Unto the married,' he says, 'I give charge, yea not I, but the Lord, that the wife depart not from her husband . . . and that the husband leave not his wife' (1 Cor. vii. 10, 11)—appealing no doubt to a saying of Jesus preserved in the tradition of the disciples. On other matters, and those most important, he distinguishes between his own decision and that 'of the Lord,' and does but give his 'judgment' as 'one that has found mercy' (1 Cor. vii. 10-25). He also gives his own opinion as a spiritual man to whom the really spiritual will listen (1 Cor. xiv. 37, 38), and he refers to the general custom of the churches (1 Cor. xi. 16, vii. 17, iv. 17). But the congregation administered its own affairs in a completely democratic manner. The story of the incestuous Corinthian is a crucial instance. Paul is sure of what will take place; he is present in spirit at the meeting of the believers, but it is the meeting itself which passes sentence of exclusion. 'St Paul's spirit,' as Bishop Ellicott puts it, 'with the associated power of Christ, is present with the convoked synod, and with that synod passes the authoritative sentence' (Comm. on 1 Cor. v. 3). The older apostles had just as little official authority, just the same scope for moral influence. When Paul met them at Jerusalem in 51 A.D., they did not decide for the believers generally, but for themselves and their own course. They gave Paul and Barnabas 'the right hand of fellowship' that 'they should go unto the Gentiles.' Again, Paul felt he had to do, not with a board of officials, but with men whose past gave them great moral weight. In the second chapter of Galatians he never once uses the name 'apostle,' but he does mention 'the men of repute,' 'those who were reputed to be pillars.' Peter and John owed their position in great measure to their personal character, and James also to the fact that he was the brother of Jesus.

It may be objected that, anyhow, some official government must have been required in the early Christian gatherings, and that Paul implies that

there were persons who presided in the Thessalonian Church (1 Thess. v. 12). To which the answer is, 'That no doubt government existed, but that it was the government of those who were marked out for it by supernatural or natural gifts, not of officials.' We have seen already, that 'governments' are classed among the miraculous gifts of the Spirit. Further, the first converts, or those in whose house the church met (Rom. xvi. 5; 1 Cor. xvi. 19), would naturally direct the others, and take the lead in the congregation. 'I beseech you, brethren (ye know the house of Stephanas, that it is the first-fruits of Achaia, and that they have set themselves to minister unto the saints), that ye also be in subjection unto such, and to every one that helpeth in the work, and laboureth' (1 Cor. xvi. 15). Here the ministry or deaconship is one with the episcopate or superintendence. All is spontaneous, nothing official. The profusion of miraculous gifts prevented any desire for official teachers, and would have thrown them into the shade had they existed. Nor, some would add, could the apostles have thought of providing the churches with a regular government to last after their own death, though even so early a writer as Clement of Rome attributes this design to them. The fact, it is said, that the apostles, like the other Christians, confidently expected the coming of the Lord in their own time, proves this theory untenable.

Philippi was the earliest of the European churches, and there St Paul, towards the close of his life, does salute 'the saints' with the 'bishops and deacons.' Possibly, even then, these titles were beginning to be attributed, the former, to those who were the acknowledged leaders of the congregation; the latter, to those who devoted themselves to furthering and helping on its work. In later books of the New Testament canon, there is frequent mention of bishops or presbyters and deacons. And in the Acts the origin of these offices is traced back to the apostles themselves, and to the very beginning of the gospel. We are as yet, however, a long way from the Presbyterian system, because the office of teaching and preaching is quite separate from that of the presbyter. He was not a minister or preacher, but an 'overseer' or 'shepherd' of the church (Acts, xx. 28). He replaced the presbyters of the Jewish synagogue who presided over its discipline. And we are still further from diocesan episcopacy. Never once, from the beginning to the end of the New Testament, is 'a threefold ministry' of bishops, priests, and deacons so much as hinted at. On the contrary, bishop and presbyter are two words for the same office. The presbyters of Miletus (Acts, xx. 17) are also its bishops (verse 28); so are the presbyters in Crete (compare Titus, i. 5 with 7). The author of 1 Tim. iii. 7 having described the qualifications of a bishop, passes straight to those of the deacon, knowing nothing of any third office. True, it has been suggested—e.g. by Rothe (*Anfänge der Christ. Kirche*, p. 173, seq.) and by Bishop Lightfoot—that diocesan episcopacy may have sprung up at the close of the apostolic age. But it was unknown to Clement of Rome about 120 A.D. 'In his epistle,' says Bishop Lightfoot, 'there is no mention of episcopacy properly so called, for bishop and presbyter are still synonymous terms (see Clem. Ep. i. 44-47).' Precisely the same argument may be drawn from the 'Teaching of the Apostles' (xv.), and the Shepherd of Hermas (*Vis.* iii. 5). These authorities carry us well into the 2d century. An analogue to the diocesan bishop has been seen by some in the 'angels' of the Revelation. They are the guardian spirits of the churches, or possibly personifications of them, but not human rulers, as Bishop Lightfoot with others, before and since, has conclusively proved.

In the pastoral epistles, supposed by the more advanced critics to have been written in St Paul's name against the Gnostic heresies of the 2d century, we get closer to the point. There Titus and Timothy are certainly empowered to guard the faith, to appoint bishops or presbyters in every city, and to exercise authority over them. There is a tendency to identify the bishop or presbyter with the teacher or preacher, for the bishop is to be 'apt to teach' (1 Tim. iii. 2), but the identification is not yet complete, for it is taken for granted that only some bishops teach (1 Tim. v. 17). The recurrence of such phrases as 'sound doctrine,' and the position of Timothy and Titus, make us feel that we are already on the threshold of the Catholic Church with its rule of faith and its hierarchy. But even here much is lacking. Timothy and Titus are temporary delegates of the apostle, not diocesan bishops. It is in the Ignatian epistles that the Rubicon is passed, and here indisputably, in any case as early as the middle of the 2d century, the claims of bishops, in the modern sense, are insisted upon perpetually. It is useless to multiply quotations from writers of later date. By the time of Irenaeus (190 A.D.), the diocesan episcopate was established throughout the Roman world. The old enthusiastic life of the early Christian meetings was replaced by the rule of the hierarchy. Even Ignatius had not reached the view which is familiar to Irenaeus, and still more to Cyprian, that bishops are the successors of the apostles, and the channels through which primitive tradition is conveyed to successive ages. Thus, it is held by many, the Catholic Church arose, formed by a kind of necessity in the struggle against the exaggerated doctrines of the Gnostic sects, which threatened to dissolve Christianity in systems of fantastic and variable speculation. The canon or collection of New Testament books, with binding authority equal to that of the Old Testament, the episcopacy united with itself, the appeal to apostolic tradition, all arose from the same need, and on this triple foundation the Catholic Church was built.

Two other points, however, deserve notice. First, Jerome (died 420) (on Titus, i. 5; *Ep.* i. 46) and an earlier writer, whose works are printed with those of St Ambrose (on 1 Tim. iii. 8, 9, 10), perceived that bishops and presbyters had been originally one, and that the current distinction could claim no higher sanction than the custom of the church. Jerome's words, than which nothing can be more clear and strong, were incorporated in the *Decretum*, the earliest mediæval collection of canon law (*Dist.* xciii. c. 24; xcv. c. 5), and thus all through the middle ages the schoolmen retained some idea of the real history of the office. Next, even in the 4th century, the church had not reached the modern principle that a bishop alone can confer valid orders. Thus, the Council of Ancyra in 314 A.D. (canon 13) assumes that presbyters may ordain presbyters with the bishop's sanction. The fathers of the council recognised of course the episcopal authority, but they did not attribute any supernatural efficacy to the imposition of episcopal hands.

The foregoing is a statement of the opinions, and the arguments on which these are based, held by the less conservative New Testament scholars both in England and Germany. Their argument has been given the more fully as still being much less known in England than the time-honoured High Church view, which has been for centuries the consistent theory of the whole Catholic Church. That theory of course is a perfectly simple and intelligible position, and the attitude of believers towards it depends mainly on the view they hold as to the literal interpretation of Scripture. For

apart altogether from the much wider and more difficult question, how far the general development in dogma of the whole body politic of the church is itself the outward evidence and expression of Christ's promised presence and guidance to the end of the world, the High Church theory of the apostolical succession of bishops—the representatives of the apostles, and through them of the Lord himself—finds strong support from the plain words of Scripture and the unforced exegesis of the same.

We must content ourselves with a brief summary of the later history of the office; and here it will be convenient to begin with the Roman Catholic and Eastern churches. There the duties and power of bishops remain much as they were in the middle of the 3d century, except so far as they have been curtailed by the rise of the papal power in the West, by the institution of Patriarchates and the interference of the state in the East. The Council of Trent requires the bishop to preach the word of God, and to maintain purity of doctrine among clergy and people. He has to superintend divine worship, and is bound to visit all the churches of his diocese at least once in every two years. He approves priests, and gives them faculties to hear confessions. He makes laws for his diocese, without power, however, to alter the common law of the church; decides ecclesiastical causes in the first instance; can suspend his clerical or excommunicate his lay subjects; he collates to all benefices, except those reserved to the pope; he directs the administration of temporal goods belonging to the diocese; he can dispense from his own laws, and, within certain narrow limits, from the law of the church. Such is the jurisdiction or ruling power of a bishop, but he is by no means supreme or unfettered even in his own diocese. He is subject by divine law to the councils of the church, and, as Roman Catholics believe, to the pope, and by ecclesiastical law he is in subordination to patriarchs, metropolitans, &c. In respect of orders—i.e. in power of consecration and the like—he has no superior, nor do pope or patriarch pretend to higher power than that of a simple bishop. He alone can consecrate other bishops, and ordain priests, and he alone, according to the Roman Catholic theory, is the ordinary minister of confirmation.

He is now addressed in the Latin Church as 'Most Illustrious and Reverend Lord,' though once titles which have become peculiar to the pope—e.g. 'Most Holy, Most Blessed Lord,' 'Your Holiness,' 'Servant of the Servants of God,' were common to mere bishops. His insignia are the ring, pectoral cross, episcopal throne, mitre, pontifical vestments, gloves, and sandals.

Bishops were in the earliest ages chosen by the people, subject to a veto by the bishops of the province (Cyprian, *Ep.* lxxviii.). In 325 A.D. the first Nicene Council (canon 4) recommended appointment by the provincial bishops, subject to confirmation of their choice by the metropolitan. Greek canonists understood this canon as annulling the old form of popular election, and at present the Greek orthodox bishops are nominated by the patriarch, though in Russia the final nomination rests with the czar. In the West the canon was understood to leave the popular rights of election unimpaired, merely requiring the presence of the bishops of the province, and confirmation by the metropolitan. In the 11th century the right of election passed to the Cathedral Chapter, and the pope gradually engrossed the sole right of confirmation, till at last Clement V. and his successors claimed the right of nomination also, first in certain cases, and then absolutely. Since then the pope has restored the right of election to the chapters in Prussia, Hanover, the Upper Rhine, Switzerland, and the

Austrian archbishoprics of Salzburg and Olmütz, with their suffragan sees, the respective governments having a right of veto. In Austria, with the exceptions just mentioned, in Bavaria, France, Spain, Portugal, Brazil, and Spanish America, the head of the state nominates. The election is purely papal in Belgium, also in Holland, Great Britain and Ireland, North America, and other Protestant countries. A right of recommendation, however, is conceded to the Roman Catholic chapters in Belgium, Holland, and England, to chapters and parish priests in Ireland, to the bishops of the province in North America. The right of consecration, which used to belong to the metropolitan and two other bishops, is now reserved to the pope, or a bishop nominated by him. There are about 180 archiepiscopal and 750 episcopal sees in the Roman Catholic Church. In Ireland there are 4 archbishoprics, 24 bishoprics; in England, 1 archbishopric, 15 bishoprics; in Scotland, 2 archbishoprics, 4 bishoprics. Altogether there are about 120 Roman Catholic sees in the British empire. In the United States there are nearly 100. Besides these, there are the titular bishops, till the pontificate of Leo XIII. called bishops in *partibus infidelium*. They have received episcopal consecration, but have no regular jurisdiction. They assist some other bishop, or are delegates of the pope where the hierarchy is not established.

Passing to the Reformed churches, we find the theory of the Anglican much the same as that of the Roman episcopate, except that in England the authority of the crown has replaced that of the pope. The Anglican bishop is said, though the statement is disputed by Roman Catholic controversialists, to descend in direct line of consecration from his predecessors in the middle ages. He alone can ordain, confirm, and consecrate churches. He institutes to benefices and licenses curates; he has the right to preach throughout the diocese, to inspect the churches and churchyards. He can withdraw the licenses of curates, who may, however, appeal to the metropolitan. He is *ex officio* president in the Consistorial Court. With regard to criminal clerks his power is very limited, not only because the final decision rests with the Queen in council, but also because the English law protects the interests of the inferior clergy with a zeal unknown to the modern canon law of the Roman Church. Thus, whereas the Council of Trent permits a bishop to decide in cases of certain grave charges against clerks 'without formal trial, having simply ascertained the truth of the fact,' an Anglican prelate has no such power. He may institute a commission of inquiry, and decide the case with three assessors, one of whom must be a barrister, or he may at once prosecute in the Superior Court. If he himself passes sentence, an appeal lies to the Court of Arches in the province of Canterbury, to the Chancery in the province of York, and ultimately to the Privy-council. If a bishop refuses to institute a clerk to a benefice, the appeal is first to the archbishop and then to the Privy-council. There are in England and Wales two archbishops and thirty-two bishops, besides twenty-three bishops-suffragan or assistant bishops, the archbishops and twenty-four of the bishops having seats in the House of Lords. There are two archbishops and eleven bishops in the disestablished Church of Ireland; seven bishops in the Episcopal Church of Scotland, one of whom is called Primate; eighty-one colonial, eleven missionary bishops; and seventy bishops in the Episcopal Church of the U.S.

The early Lutherans were singularly moderate and rational in their attitude to episcopacy. They denied its divine institution, but they were quite willing to tolerate it, when circumstances made it expedient to do so. In Germany the name of

bishop fell into disuse, or was retained as a merely civil title, or revived for a short time, and then allowed to drop; and the Lutheran superintendent is a mere shadow of a mediæval bishop. On the other hand, the Lutheran churches of Denmark and Scandinavia have always been episcopal. There are seven bishops in Denmark, nominated by the crown, one archbishop and eleven bishops in Sweden; six bishops in Norway, which last are chosen by the clergy. These Lutheran bishops have the sole right of ordination, but in Sweden their disciplinary power is exercised in union with a consistory, the majority of whose members are laymen.

For the early history of the office, see Lightfoot on Philipians; Rothe, *Anfänge der Christlichen Kirche*, p. 261 seq.; Ritschl, *Entstehung der Altkatholischen Kirche*, p. 399 seq.; Baur, *Christenthum und Kirche der ersten drei Jahrhunderte*, p. 260 seq.; Hatch, *Organisation of the Early Christian Churches*; Weizsäcker, *Apostolisches Zeitalter*, p. 606 seq. The historical canonists of the Roman Catholic Church, such as Thomassin, afford abundant and trustworthy information on the episcopate in later patristic and mediæval times. Dr Wordsworth's *Theophilus Anglicanus* is a popular statement of the High Church theory by a divine of great learning; Döllinger's *First Age of the Church* (trans. by Oxenham) treats the subject in a masterly fashion from the Roman Catholic standpoint. For the Reformed churches recourse has been had to Blunt's *Church Law*, revised by Phillimore, and to the articles on the Danish and Scandinavian churches in Herzog and Plitt's *Encyclopädie für Protestantische Theologie*. See also the articles in this work on APOSTOLICAL SUCCESSION, ARCHBISHOP, ENGLAND (CHURCH OF), ORDEES, PRIEST, ROMAN CATHOLIC CHURCH.

Bishop, a beverage composed of red wine (claret, Burgundy, &c.) poured warm or cold upon ripe bitter oranges, sugared and spiced to taste, and drunk either hot or cold.

Bishop, SIR HENRY ROWLEY, composer, was born in London, November 18, 1786. His principal musical instructor was Francesco Bianchi, an opera composer settled in London. In 1806 Bishop was appointed composer of ballet music at the Opera. Among his 88 operatic entertainments were *Guy Mannering*, *The Miller and his Men*, *Maid Marian*, *Native Land*, and *The Virgin of the Sun*—all less remarkable for originality than for their flowing melodies and animated style. The opera *Aladdin* (1826) was a failure. The famous glee, 'The Chough and Crow,' is his; many of our most popular songs, such as 'Should He Upbraid,' 'My Pretty Jane,' are by him; and his, too, probably, is the setting of 'Home, Sweet Home' (see PAYNE). From 1810 to 1824 he was director of the music at Covent Garden Theatre, from 1825 to 1830 at Drury Lane, and for three years more at Vauxhall Gardens. One of the first directors of the Philharmonic Society, he for nine years conducted the concerts of Ancient Music. In 1839 he received the Oxford degree of Mus. Bac., in 1853 of Mus. Doc.; and from 1841 to 1843 he was Reid professor of Music in the university of Edinburgh. In 1842 he was knighted, and in February 1848 was elected professor of Music in the university of Oxford. In his later years he was in very necessitous circumstances. He died of cancer, April 30, 1855.

Bishop-Auckland, a town in the county, and 9½ miles SW. of the city, of Durham, stands on an eminence 140 feet above the confluent Wear and Gaunless. Its abbey-like palace of the bishops of Durham was founded about 1300 by Bishop Antony Bek, and rebuilt by Bishop Cosin shortly after the Restoration. The town-hall is a handsome edifice of 1863, with a spire 100 feet high. There are cotton-mills, engineering-works, and large neighbouring collieries. Pop. (1851) 4400; (1861) 6480; (1881) 10,097; (1891) 10,527.

Bishop's Castle, a municipal borough of Shropshire, 22 miles SW. of Shrewsbury, and 9½ WNW. of Craven Arms junction by a branch line (1865). Till 1832 it returned two members to parliament. It is irregularly built on a hill slope. The bishops of Hereford had formerly a castle here. Pop. 1586.

Bishop-Stortford, a town of Hertfordshire, on the Stort, 12 miles ENE. of Hertford. It chiefly consists of two streets in the form of a cross. It carries on a trade in grain and malt. Bishop-Stortford was in Saxon times the property of the bishops of London. Pop. 6594.

Bishop's Waltham, a town of Hampshire, 9½ miles SE. of Winchester. It has been immemorially the property of the see of Winchester. There are remains of a castle, built in 1135 by Bishop Henry de Blois, and reduced to ruins during the civil wars of the 17th century. Pop. of parish, 3886.

Bishopweed, or GOUTWEED, also Goatweed, or Herb Gerard (*Egopodium Podagraria*), an umbelliferous weed common in hedges and grass plots, and exceedingly difficult of extirpation on account of its creeping rhizomes. It is eaten by cattle, and the leaf stalks were formerly boiled and eaten as greens. The root-stock was long esteemed as a remedy for gout.

Biskra, a town of Algeria, 150 miles SW. of Constantine by rail, in an oasis watered by the Wady Biskra and by springs. Pop. 7166. Biskra was known to the Romans as *Zaba*, and under the Moors it became a large town. It is now a favourite health-resort for Europeans. Here in 1663 some 71,000 persons died of the plague.

Bisley, a village of Surrey (pop. 700), 4 miles NW. of Woking; to Bisley Common were removed in 1890 the meetings of the National Rifle Association—the Princess of Wales having opened the meeting on June 12 of that year by firing a rifle—and Bisley became the new Wimbledon of volunteer marksmen.—Another Bisley is in Gloucestershire, 3 miles E. of Stroud; pop. of parish, 5171.

Bismarck, capital of North Dakota, U.S., is on the east side of the Missouri, here crossed by the Northern Pacific Railway on an iron bridge which cost £200,000. Large quantities of goods are forwarded hence by steamers to the upper settlements of the river Missouri, which is navigable 1200 miles above Bismarck. Great sums have been spent by the government in digging out the sand bars from the river above the town. Pop. (1890) 2260.

Bismarck Archipelago is the name officially given by Germany to New Britain, New Ireland, New Hanover, and several smaller adjoining islands in the South Pacific, since in 1884 they became a German dependency. See NEW BRITAIN, &c.

Bismarck-Schönhausen. OTTO EDUARD LEOPOLD, PRINCE VON, DUKE OF LAEENBURG, chancellor of the German empire and foremost statesman of his time, was born 1st April 1815, at Schönhausen in Brandenburg, of an old family distinguished both in war and statesmanship. Bismarck received his university education at Göttingen, Berlin, and Greifswald, where he studied law and agriculture, but became more distinguished as a swordsman than as a reading man. After finishing his studies, he lived for a time on his estates. Before 1847 he was little heard of, but about that time he began to attract attention in the new Prussian parliament as an ultra-royalist, and a fierce but unsuccessful opponent of the constitutional demands resulting from the March revolution of 1848. He opposed the scheme of a German empire as proposed by the Frankfurt parliament of 1849, for the reason that

the title to the imperial dignity offered to the king of Prussia was merely based on the popular will and not on the concurrent assent of the German sovereigns as well. His diplomatic career commenced in 1851, when he was appointed Prussian member of the resuscitated German diet of Frankfurt. Here he began to manifest that zeal for the interests and aggrandisement of Prussia, which has since undeviatingly guided him, often regardless of the means. In the diet, he gave open expression to the long-felt discontent with the predominance of Austria, and demanded equal rights for Prussia. At Frankfurt he remained till 1859, when he beheld in the approach of the Italian war an opportunity of freeing Prussia and Germany from the injurious dominance of Austria; but his views of energetic action being not yet shared by the cautious and pacific prince-regent, Bismarck was meanwhile recalled from the diet and sent as minister to St Petersburg. In the spring of 1862 King William, on the urgent advice of the Prince of Hohenzollern, transferred Bismarck as ambassador to Paris, in order to give him an insight into the politics of the Tuileries, before intrusting him with the direction of affairs at home. During his short stay at Paris Bismarck visited London, and had interviews with the leading politicians of the time, including Lord Palmerston and Mr Disraeli. In autumn, when the king's government could not obtain the consent of the lower house to the new military organisation, Bismarck was recalled, to take the portfolio of the ministry for foreign affairs, and the presidency of the cabinet. Not being able to pass the reorganisation bill and the budget, he closed the chambers (October 1862), announcing to the deputies that the king's government would be obliged to do without their sanction. Accordingly, the army reorganisation went on; and the next four sessions of parliament were closed or dissolved in the same way, without the government obtaining, or even caring to obtain, the sanction of the house. When the 'Conflict Era,' as it was called, approached a crisis, the death of the king of Denmark re-opened up the Schleswig-Holstein question, and excited a fever of national German feeling, which Bismarck was adroit enough to work so as to aggrandise Prussia by the acquisition of the Elbe Duchies, and reconcile his opponents to his high-handed policy by pointing to the success of the newly-modelled army. Throughout the events which ended in the humiliation of Austria at the battle of Königgrätz (1866), and the reorganisation of Germany under the leadership of Prussia (see GERMANY), Bismarck was the guiding spirit; and such is the magic of success, that, from being universally disliked, he now became the most popular man in Germany. It was Bismarck that negotiated the neutralisation of the Luxemburg territory (1867).

The action of France in regard to the candidature of Prince Leopold of Hohenzollern for the throne of Spain gave Bismarck the opportunity of carrying into action the intensified feeling of unity amongst Germans. During the war of 1870-71, Bismarck was the spokesman of Germany; he it was that in February 1871 dictated the terms of peace to France. Having been made a count in 1866, he was now created a prince and chancellor of the German empire. From the peace of Frankfurt (10th May 1871) the sole aim of Bismarck's policy, domestic and foreign, was to consolidate the young empire of his own creating, by rendering its institutions more beneficent, authoritative, homogeneous, and stable; and again by securing it, through alliances and political combinations, against attack from without. Thus, conceiving the unity of the nation and the authority of its government to be endangered by the Church of Rome, and

its doctrines of Papal Infallibility, he embarked on that long and bitter struggle with the Vatican, called the Kulturkampf, in the course of which the Imperial and Prussian parliaments passed a series of most stringent measures (Falk or May laws) against the Catholic hierarchy. But Bismarck had underrated the resisting power of the Romish Church, and motives of political expediency gradually led him to modify or repeal the most oppressive of the anti-papal edicts, leaving the Catholics virtual masters of the field. Otherwise, his domestic policy has been marked, among other things, by a reformed coinage, a codification of law, a nationalisation of the Prussian railways (as a preliminary step to Imperial state lines), fiscal reform in the direction of making the empire self-supporting (i.e. independent of 'matricular contributions' from its component states), repeated increase of the army and the regular voting of its estimates for seven years at a time (Military Septennate), the introduction of a protective tariff (1879), and the attempt to combat social democracy and its attendant evils by means at once repressive and remedial—among the latter being a lightening of the burden of direct taxation, the insurance of working men against suffering from accidents, indigence, and old age, with other economic experiments, which have caused Bismarck to be called the greatest state socialist of the age. With a view to improve the finances of the empire, Bismarck has repeatedly tried to establish various government monopolies, of tobacco, &c., but hitherto without success.

In 1884 Bismarck inaugurated the career of Germany as a colonising power, a new departure which brought him into sharp but temporary conflict with the England of Mr Gladstone. For the rest, his foreign policy aimed principally at isolating France and rendering her incapable of forming anti-German alliances. On the other hand, he gradually combined the central powers of Europe into a peace-league, aiming at counteracting the aggressiveness of Russia and France, separately or combined, on the Danube or the Rhine. The nucleus of this peace-league was formed in 1879 by the Austro-German Treaty of Alliance (published February 1888), which Italy joined in 1886. It entitled Bismarck to be called the 'Peace-maker' of Europe, a character he first acquired when, as 'honest broker' between Austria and Russia, he presided over the Berlin Congress in 1878. The phrase, 'man of blood and iron,' is based on 'the Iron Chancellor's' own use of the words in a speech in 1862.

Bismarck's life was repeatedly threatened, and twice actually attempted—once at Berlin in 1866, just before the Bohemian campaign, by a crazy representative of popular dissatisfaction with Bismarck as champion of absolutism and fratricidal war; and again in 1874 at Kissingen, by an Ultramontane tinsmith named Kullmann. In 1885 Bismarck's 70th birthday was celebrated as a great national event. As a statesman he was imperious yet prudent, jealous, vindictive, and even unscrupulous—faults that sprang from his fervid patriotism; but in private life he could be genial, witty, and entertaining. He was tall and massive in person, fair and fresh of complexion, and quiet and cultured in manner. Though no orator, in public speeches he wielded the mother-tongue with trenchant vigour (see GERMANY); and he spoke French, Russian, and English with facility. Soon after the accession of William II., the relations between the veteran and his young master became strained. The emperor resented the chancellor's independent and masterful ways, and Bismarck felt driven to resign in March 1890, retiring with the title of Duke of Lauenburg. He now became, and—though there was a formal reconciliation in

1894—continued, a caustic and inconvenient critic of the emperor, the successive chancellors, and the new polity generally. In 1895 his birthday was again a national celebration, though the Reichstag refused to present an address of congratulation. Bismarck died 30th July 1898, and an autobiography was printed immediately after.

There are German lives by Busch (3d ed. 1890) and Görlach (5th ed. 1885); and by Lowe (2 vols. 1886, 2d ed. 1888; abridged 1895). See also *Die Bismarck Litteratur* (1895); and Lowe, *Bismarck's Tabletalk* (1896).

Bismark, a small Prussian town of 2319 inhabitants, 35 miles N. of Magdeburg.

Bismark, FRIEDRICH, COUNT OF (1783–1860), born at Windheim in Westphalia, spent most of his life in the Württemberg army, but from 1804 to 1807 was in the English service. He wrote on cavalry tactics and organisation.

Bismuth (sym. Bi, eq. 210) is a brittle metal, white with a faint red tinge. It is found native in Cornwall, France, Peru, Siberia, &c., but is mostly obtained from Saxony. It exists also in combination with oxygen, carbonic acid, lead, tellurium, &c., but the native (impure) metal is preferred. The ore is placed in inclined iron tubes, and heat applied, when the metal melting and partly volatilising, runs down to the receivers, and when transferred to moulds, solidifies with a crystalline texture. When pure, it crystallises more readily than any other metal; and it exhibits the singular anomaly, that when it has been exposed to great pressure its

Bismuth :

a, example of native bismuth from Redruth, in Cornwall;
b, crystal of bismuth.

density becomes less. It may be distilled at a high temperature, and repels a magnet more than any other metal. Heated in the air, it burns with a blue flame, forming yellow fumes of oxide. Bismuth unites readily with other metals, forming Alloys (q.v.). The most remarkable of these is called fusible metal, consisting of 2 of bismuth, 1 of lead, and 1 of tin, the melting-point of which is 200·75° F. (93·75° C.), or 12° below the boiling-point of water. Spoons made of this alloy, therefore, readily melt when placed in boiling water: a favourite trick with amateur conjurers. A still more fusible metal is obtained by the addition of mercury, and this is used in forming moulds for toilet-soaps or in taking casts. Bismuth has a specific gravity of 9·83, and melts at 507° F. (264° C.).

Bismuth forms several compounds of service in the arts and in medicine; it combines with oxygen to form several oxides, of which the trioxide, Bi₂O₃, is the most important. It may be prepared by boiling together a solution of the subnitrate of bismuth, BiONO₂, and caustic soda, NaHO, when the oxide, in combination with water, is thrown down, and nitrate of soda remains in solution. It is employed in the porcelain manufacture as an agent for fixing the gilding, and for increasing the fusibility of fluxes, at the same time neutralising the colours which are often communicated by them. The ternitrate of bismuth is prepared by acting upon the metal bismuth with a mixture of one part of commercial nitric acid and

one part of water, and applying heat. The subnitrate or basic nitrate of bismuth receives the names of *Pearl White*, *Pearl Powder*, *Blanc de Fard*, and *Blanc d'Espagne*. It is used as a cosmetic, but is apt to become gray in tint, and even brown or black, when sulphuretted hydrogen, often evolved from sewers, cesspools, and drains, comes in contact with it. The subnitrate and subcarbonate of bismuth are used in medicine as very soothing, feebly astringent sedatives when applied to irritated mucous membranes, and are of great value in various forms of stomachic disease; while externally they are used as an application to scrofulous sores. The citrate of bismuth in combination with ammonia being very soluble, is more rapid and irritant in its action than the soluble salts last mentioned, but is of special use in cases of relaxation with excessive discharge. Bismuth salts sometimes contain arsenic, and must be used with caution. The 'bismuth breath' is a peculiar garlicky odour often felt in the breath of those who have taken bismuth preparations for some time. The cause of this is not clearly known, although at various times the presence of arsenic or tellurium as impurities has been blamed for it; but it would seem that it may be produced even when these are absent.

Bison (Lat.; Old High Ger. *Wisand*), a genus of wild cattle, represented by two rapidly disappearing species in Europe and America. The European Bison (*Bos europæus* or *Bonassus*), wrongly confounded with the Aurochs (*Urus*), was common in Europe in Roman times, but has gradually been all but exterminated. It only persists in a dwindling herd 'in the imperial preserves of Lithuania, and in the wilds of the Ural and Caucasus.' The bison measures about 10 feet in length, stands about 6 feet high, and is extremely strong, especially in its fore-parts. Old bulls can knock down trees 5 or 6 inches in diameter, and can readily cope with wolf or bear. The most striking differences between a bison and an ox are the hump just behind the neck, the broader convex forehead, the longer limbs, the shaggier head and shoulders. There are also internal differences, such as the presence of an additional rib. The hump is due to the long spines of the backbone bodies in that region, and to the enormous muscles working the head. The horns are short and very far apart, a little curved inwards at the point, and fixed not at the ends of the top-most ridge of the head, but considerably in front of it. The long shaggy hair on head and breast is of a dusky brown colour, and is cast in summer. The females are not so large as the males, nor do they exhibit the same shagginess of the fore-parts. The bison is the largest quadruped now existing in Europe, although within the historic period there existed along with it an even larger ox (*B. primigenius*), the *Uris* of the ancients, abundant in the time of the early Roman emperors. The ancient *Bonassus* was apparently the still extant bison. The food of the bison consists of grass and brushwood, and the leaves and bark of young trees. Its cry is peculiar, 'resembling a groan or a grunt, more than the lowing of an ox.' It does not attain its full stature till after its sixth year, and lives for about thirty or forty years. The period of gestation appears to be the same as that of the ox. The bison has never been reduced to subjection by man, and the domestication even of individuals taken young, has been very partial. It generally shows a great aversion to the domestic ox. The bison is generally very shy, and can only be approached from the leeward, its smell being very acute. It is easily provoked, and is not approached without danger. It runs very swiftly, although it cannot long continue its flight, galloping with its head very low, so that the

hoofs are raised higher than the head. Few authorities derive any of the domestic breeds of cattle from the bison, but this theory has been recently proposed by Wilekens. It is usually supposed, however, that all have descended from *B. primigenius*.

There is no historical record that the bison ever existed in Britain; but remains of this, or of a very closely allied species, are found in pliocene freshwater beds in several parts of England, as well as on the continent of Europe. The most abundant fossil species is *B. prisens*, but other closely related forms are also known (*B. sivalensis*, *latifrons*, *antiquus*).

The American Bison (*B. Americanus*) is interesting as the only living species of the ox family indigenous to America, except the Musk Ox (q.v.) of the subarctic regions. It is commonly called *Buffalo* by the Anglo-Americans, but must be distinguished from the true Buffalo (q.v.). The bison was within recent times very abundant in America, especially in the prairies beyond the Mississippi, and from 63° N. lat. to New Mexico. Even in the 19th century it was still found in Ohio. Now it is nearly extinct—a result of hard winters, cattle-ranching, railways, and immigration. In 1886 the Smithsonian Institute sent out emissaries to procure a few skins and skeletons. On inquiry it was found none were left save in the Yellowstone Park, and a few in Montana and in Texas,

American Bison.

the Montana herd comprising sixty head; twenty-five were secured for the institute. The Canadians preserve a herd or two. The bison used to congregate in large herds, and when migrating, travelled in solid columns of thousands and tens of thousands, which could hardly turn or arrest their progress for the pressure of the masses from behind on those in front. They were of the utmost importance to the Indians, who shot them in the chase, or drove them into great snow pounds, or frightened them over precipices, and in other ways killed them in enormous numbers.

The differences between the American and European bison are quite immaterial. The former is slightly smaller, shorter in limb, and blunter in horn. The fore-parts are still more shaggy, and retain most of their shagginess in summer. In their palmy days at least, the male and female American bison lived apart in separate herds, and the bulls, though usually pacific, were dangerous at the breeding or fighting time. The grizzly bear is said to be the only animal which could dare singly to attack a bison.

The economic importance of the bison was once great. The flesh, like coarse-grained beef, was tender and juicy, while the tongue and marrow bones and hump were specially prized. The hump formed pemmican; the fat, tallow; the skins, clothing or tent and canoe covers; the hair, cloth; and the dried droppings, fuel. But all this, and the noble animals themselves, will soon have receded from life into history. See J. A. Allen, *American*

Bisons, Living and Extinct (Cambridge, Mass. 1876).

Bissa'gos Islands, a group of small volcanic islands, about 30 in all, off the west coast of Africa, opposite the mouth of the Rio Grande. The islands are inclosed by a reef, and, with a few exceptions, are thickly wooded; many of them densely peopled. There are several fine ports, but the climate is excessively dangerous for Europeans. The principal islands belong to the Portuguese, whose governor resides at Bolama.

Bissão, an island and Portuguese station closer to the African coast than the Bissagos.

Bissen, WILHEM, a Danish sculptor, was born in Sleswick in 1798, and from 1823 to 1833 studied in Rome under Thorwaldsen, who, in his will, commissioned him to complete his unfinished works. In 1830 he was made director of the Academy of Arts, Copenhagen, where he died 10th March 1868. Among his masterpieces are the 'Valkyrie,' 'Cupid sharpening his Arrow,' and 'Moses;' his 'Orestes,' and a frieze 134 feet long, perished in the burning of the Christiansborg at Copenhagen (1884).—See the life by Plon (2d ed. Paris, 1871).

Bistort (*Polygonum bistorta*), a perennial plant, 1 to 1½ feet high, with a simple stem, ovate subcordate and wavy leaves, the radical leaves tapering into a long footstalk, and one dense terminal cylindrical spiked raceme of flesh-coloured flowers. The root is about the thickness of the little finger, blackish-brown externally, reddish within, and tortuous (whence the name bistort, and probably also the other popular name of Snake-root). The whole

Bistort (*Polygonum bistorta*):

a, b, c, flowering stem and root stock; d, a flower; e, a fruit.
(From Bentley & Trimen.)

plant is astringent, containing much tannin; the root is one of the strongest vegetable astringents, and was formerly much employed in medicine, both internally and externally, in hemorrhages and many other complaints. Bistort is a native of meadows in Europe, and is found in Britain, but is by no means common. In times of famine the root has been used after washing as a source of starchy food. See POLYGONUM.

Bistre is a pigment of a warm brown colour, prepared from soot, especially the soot of beech-wood.

Bistritz, a town of Transylvania, beautifully situated on the Bistritza River, 50 miles NE. of Klausenburg. Pop. 9109.

Bisutum. See BEHISTUN.

Bit. See BRIDLE.

Bitche (Ger. *Bitsch*), a German town of Lorraine, in a wild and wooded pass of the Vosges, 49 miles NNW. of Strasburg by rail. Its citadel crowns a precipitous and isolated rock in the middle of the town. The Prussians under the Duke of Brunswick attempted to surprise it in 1793, but failed. It resisted the Germans for seven weeks in 1815, and did not surrender till three weeks after the close of the war of 1870-71. Pop. 2764.

Bithur, a town in India on the Ganges, 12 miles NW. of Cawnpore. It is particularly devoted to the worship of Brahma, has numerous pagodas, and is a favourite resort for pilgrims. The stronghold of the infamous Nana Sahib, it was captured by Havelock in 1857. Pop. (1881) 6685.

Bithynia, an ancient division of Asia Minor, separated from Europe by the Propontis (Sea of Marmora) and the Bosphorus, and bounded N. by the Euxine. It contained the famous Greek cities or colonies of Chalcedon and Heraclea; and at later periods, Nicomedia, Nicaea, and Prusa were flourishing cities of Bithynia. The Bithynians were supposed to be of Thracian origin. The country was subdued by the Lydians, and afterwards became a part of the Persian dominion under Cyrus. But during the decline of the Persian empire, it became an independent kingdom under a dynasty of native princes, who made Nicomedia their capital. The last king, Nicomedes III., made the Romans his heirs, and with a large addition from the Pontic kingdom, Bithynia became a province of the empire (74 B.C.). Under Trajan, Bithynia was governed by Pliny the Younger. The Emperor Diocletian made Nicomedia his habitual residence. In 1298 Osman the Turk broke into the country; and in 1326 Prusa, or Brusa, then the chief town of Bithynia, became the capital of the kingdom of the Osmanli.

Bitlis, a town of Turkish Armenia, 120 miles SE. of Erzerum. It is situated at an elevation of 5470 feet above the sea, in a deep ravine traversed by the river Bitlis, one of the head-streams of the Tigris. Bitlis is a straggling, irregular place, covering a large surface of ground, and surrounded by bare limestone mountains, rising 2000 feet above the valley, which is filled with orchards and gardens, and watered by numerous streams and springs. The population numbers about 15,000, of whom two-thirds are Mohammedans and one-third Armenians. The Persians defeated Solymán the Magnificent near Bitlis in 1554.

Bitonto (ancient *Butuntum*), a town of Italy, 10 miles WSW. of Bari. It is situated in a fruitful plain about 5 miles from the sea, is well built, and has a fine cathedral and a theatre. In the vicinity the Spaniards defeated the Austrians in 1734. Pop. 22,726.

Bittenfeld. See HERWARTH.

Bitter Apple. See COLOCYNTH.

Bitter Cress. See CRESS.

Bitter King (*Soulamea amara*), a shrub or small tree of the natural order Simarubaceae (see QUASSIA), a native of the Moluccas and Fiji Islands, which has received its name from its intense bitterness.

Bittern (*Botaurus*), a genus of birds nearly related to the herons (Ardea). Bitterns are chiefly distinguished from herons by the long, loose plumage on the front and sides of the shorter neck, and by the greater length of their toes, the middle one being as long as the shank. The feathers can be erected so as greatly to increase the apparent size of the bird. The back of the neck is downy or almost bare.

They are almost all solitary birds, inhabiting reedy and marshy places, where they lie hid during the day, and will almost allow themselves to be trodden upon before they take wing. They feed during the night, and then often rise to a great height in the air, making the night noisy with loud resounding cries. Their food consists chiefly of frogs, and partly, also, of fish, lizards, water-insects, &c., and even of small birds and quadrupeds. The claw of the middle toe is serrated on the inner edge, probably to aid in securing slippery prey. The Common Bittern (*B. stellaris*) is distributed very widely over the Old World, being found in almost

The Common Bittern.

all, at least of the temperate, parts of Europe, Asia, and Africa, which are sufficiently marshy for its manner of life. It is now rare in Britain, owing to drainage; but was formerly more common, and in the days of falconry, was carefully protected on account of the sport which it afforded. Its flesh also was in high esteem, not being rank and fishy, like that of the herons generally. In size it is rather less than the common heron; the sharp bill is about 4 inches long, the feathers on the crown of the head are greenish black, and the plumage in general of a dull yellow colour, beautifully and irregularly marked and mottled with black and reddish brown.

The bittern makes a rude nest of sticks, reeds, &c. in its marshy haunts, and lays four or five greenish-brown eggs. It has a peculiar bellowing or booming cry, especially insistent at the breeding-season. This has earned for it such English provincial names as Mire-drum, Bull of the Bog, &c., and many of its appellations in other languages, perhaps even its name Bittern (*Bitour*, *Botur*, *Botaurus*). Some naturalists used to assert that the booming cry of the bittern was produced by the bird inserting its bill into a reed; that notion, however, has long since been exploded. The animal is sluggish, and its flight is neither swift nor long sustained. When assailed, it fights desperately with bill and claws; and it is dangerous to approach it incautiously when wounded, as it strikes with its long sharp bill, if possible, at the eye.—The Little Bittern (*B. minutus*) is common in some parts of Europe, but rare in Britain. Its whole length is only about 13 inches. The American Bittern (*B. lentiginosus*), a species almost equal in size to the common bittern, and very similar to it in habits and voice, has occasionally been shot as a straggler in Britain. It is common in many parts of North

America, migrating northward and southward, according to the season. The crown of the head is reddish brown, and the colours and markings of the plumage differ considerably from those of the common bittern. The Least Bittern (*B. exilis*) is another North American species, of very small size, which is also migratory, and somewhat social in its habits. The Australian Bittern (*B. australis*) is generally diffused throughout Australia, wherever marshes or sedgy rivers occur. In habits it closely resembles the bittern of Europe. The head and upper parts generally are purplish brown, except the wings, which are buff, conspicuously freckled with brown; the throat, breast, and belly mottled brown and buff.

Bittern, BITTER LIQUID, or SALT OIL, is an oily liquid obtained during the preparation of common Salt (q.v.). When the mother-liquor of the evaporating pans ceases to deposit crystals of common salt, there is left behind in the boilers the material called bittern. It consists principally of a strong solution of common salt, along with the chlorides of magnesium and calcium, to which the bitter taste is due; but it also contains the bromides of sodium and calcium, which are valuable sources of the element Bromine (q.v.). The bittern obtained from the salt-works at Epsom was at one time the source of the sulphate of magnesium (hence called Epsom salts), but at present this salt is obtained in other ways.

Bitter Root Mountains. See ROCKY MOUNTAINS.

Bitters are prepared from an infusion of herbs containing bitter principles. Formerly the name was limited to a favourite household remedy prepared from the Garden Angelica (see ANGELICA). The roots or seeds, or both, were placed in water, and allowed to simmer for several days, when the bitter infusion was strained off for use. Coincident with the disuse of these bitters, the term assumed a wider significance, embracing all bitter infusions, and having distinctive names attached to it, indicating the origin of the bitter, as Angostura, Quassia, Gentian, or Orange Bitters. An aerated beverage, called tonic bitters, flavoured with chiretta, calumba, quassia, or gentian, is esteemed by many. The medicinal properties of bitters are mainly those of a mild tonic and pungent aromatic stimulant, and hence they are serviceable as a stomachic in cases of weakness of the digestive organs. When taken in excess, the more powerful of them are apt to do more harm than good, the tone of the stomach being undermined by the excessive stimulation. The most widely used bitter is that of the hop, to which, in part at least, are due the tonic properties of beer. The medicines known as hop bitters must not, however, be supposed to derive any virtues they possess from the hop, their nature being rather that of a purgative.

Bittersweet, or WOODY NIGHTSHADE (*Solanum dulcamara*), a plant found in hedges and thickets in Britain, and throughout the palaearctic region, also introduced into North America. The root is perennial and creeping; the annual stems climbing and trailing, 4 to 6 feet in length; the leaves acuminate with 2 lateral pinnae, the upper halbert-shaped; the flowers purple, in drooping corymbs, much resembling those of its congener, the potato, but much smaller, followed by ovate red berries of tempting appearance, which, although by no means approaching in poisonousness to those of the true nightshade (see BELLADONNA), contain an apparently variable quantity of alkaloid, and seem sometimes to have been the cause of accidents, particularly to children; although some physiologists have administered it without bad

effects. The twigs, collected in autumn after the leaves are fallen, are still occasionally used in medicine, a decoction being given in rheumatic or

Bittersweet (*Solanum dulcamara*):
a, a flower; b, fruit.

entaneous affections. It is in the stems rather than in the fruit that the peculiar succession of tastes, to which the plant owes its name, is best observed.

Bitter Vetch. See OROBUS.

Bitterwood, a name given to certain species of *Xylopia*, a genus of Anonaceæ, trees and shrubs remarkable for the bitterness of their wood, particularly the West Indian *X. glabra*. Furniture made of this wood is safe from the attacks of insects. —The fruit of some of the species, particularly *X. sericea*, is highly aromatic and pungent like pepper. *X. sericea* is a large tree, a native of Brazil; its bast tissue is used for making cordage, which is excellent.

Bitterwood is also the name of *Picramnia excelsa* (formerly *Quassia excelsa*), a tree of the natural order Simarubaceæ (q.v.), a native of Jamaica, the wood of which is now alone used in medicine, as *Quassia* (q.v.), owing to the scarcity of the *Quassia amara*, to which the name was first given. It is, botanically, very nearly allied to the true quassia, and possesses very similar properties, containing the crystallisable bitter principle called Quassite or Quassin. The wood, which is intensely bitter, is a very useful stomachic and tonic; an infusion of it is a well-known and useful fly-poison; and it appears to act as a powerful narcotic on many quadrupeds.

Bitumen, a mineral substance, remarkable for its inflammability and its strong peculiar odour; generally, however, supposed to be of vegetable origin. The name, which was in use among the ancient Romans, is variously employed, sometimes to include a number of the substances called Mineral Resins (see RESINS), particularly the liquid mineral substances called Naphtha (q.v.) and Petroleum (q.v.) or Mineral Oil, and the solid ones called Mineral Pitch, Asphalt (q.v.), Mineral Caoutchouc, &c.; sometimes in a more restricted sense it is applied by mineralogists only to some of these, and by some mineralogists to the solid, by others to the liquid ones. All these substances are, however, closely allied to each other. Naphtha and petroleum consist essentially of carbon and hydrogen alone, 84 to 88 per cent. being carbon; the others contain also a little oxygen, which is particularly the case in asphalt, the degree of their

solidity appearing to depend upon the proportion of oxygen which they contain, which amounts in some specimens of asphalt to 10 per cent. Asphalt also contains a little nitrogen. It seldom occurs quite pure, but is usually mixed with sand or other inorganic ingredients. Not infrequently it is found impregnating sandstone, limestone, shales, clay-slates, &c. Such is the character of the so-called fetid sandstones and limestones. From certain shales, marls, and slates, mineral oil is distilled in large quantities (see SHALE and MARL). Asphalt occurs plentifully on the shores and floating on the surface of the Dead Sea. It is met with in mass in many other places, as in Trinidad, at Limmer in Hanover, at Lobsan in Alsace, at Val de Travers in Switzerland, &c. Now and again it occurs also, in small quantities, in mineral veins or lodes, where it is often mistaken for anthracite. Closely related to asphalt are the pitch-like minerals called Grahamite and Albertite, which occur in fissures in the Carboniferous system of North America. The latter mineral has likewise been met with in Scotland. Some authorities also include the well-known Boghead Coal (q.v.) under the general head of Bitumen.

One of the most interesting of the bituminous minerals is that called Mineral Caoutchouc or Elastic Bitumen, and for which the new name of Elaterite has been devised, as if to support the dignity of its exaltation to the rank of a distinct mineral species. It is a very rare mineral, only three localities being known for it in the world—the Odin lead-mine in Derbyshire; a coal-mine at Montrelais, near Angers, in France; and a coal-mine near South Bury, in Massachusetts. It is elastic and flexible like caoutchouc, and may be used, like it, for effacing pencil-marks. It is easily cut with a knife. Its colour is blackish, reddish, or yellowish-brown; and its specific gravity is sometimes a little less, and sometimes a little more than that of water. It has a strong bituminous odour, and burns with a sooty flame, its composition being $\text{C}_{12}\text{H}_{10}$. Several substances occur in nature with a similar composition. Of these the best known is the mineral called Ozokerite. It is brownish, yellowish, or greenish in colour, streaked or spotted, and occurs in rudely fibrous masses, as at Slanik and Boryslaw in Galicia. It dissolves with difficulty in alcohol and ether. Various other natural products have been described as Ozokerite, to which they closely approach in chemical composition, and from which they seem to differ chiefly in their ready solubility in ether.

Bitzias, ALBERT, better known under the *nom de plume* of Jeremias Gotthelf, a popular Swiss author, bepraised by Ruskin, was born at Murten, in the canton of Freiburg, 4th October 1797. He studied theology at Bern, and became in 1832 pastor of Lützellüh, in Emmenthal, which office he retained till his death, 22d October 1854. A monument was reared to him in 1887. Bitzias has assured himself lasting popularity by his masterly delineations of Swiss popular life. His stories are characterised by rare simplicity and truth, lightened by delicate humour and graceful fancy. The best and most popular of his stories are *Käthi, die Grossmutter* (1847); *Uli, der Knecht* (1841), and its continuation, *Uli, der Pächter* (1849); and *Erzählungen und Bilder aus dem Volksleben der Schweiz* (5 vols. 1852–55). In his later years he wrote several pamphlets against the German democrats, without, however, violating those popular sympathies and liberal convictions which pervade his writings, and which at an earlier period led him vehemently to oppose the Bernese aristocracy. Complete editions of his works appeared at Berlin in 12 vols. (1856–57) and in 24 vols. (1861). A selection was edited by his son in 3 vols. (Berlin,

1878).—See Brockhaus, *Jeremias Gotthelf, der Volkschriftsteller* (1876).

Bivalves form a class of shelled animals or molluscs in which the shell consists of two limy plates or valves, lying one on each side of the body. Mussel, oyster, cockle, and clam are very familiar examples. Compared with the other two great classes of Molluscs—the snails (Gasteropods) and the cuttle-fish (Cephalopods)—the bivalves are markedly quiet and passive. The great majority live a sessile life except during their youngest stages. With this inactivity certain characters are directly associated, of which the most marked are: (1) the undeveloped structure of the head; (2) the absence of head eyes; (3) the absence of biting or prehensile organs; (4) the marked development of large plate-like gills producing nutritive as well as respiratory currents; and (5) the presence of thick limy shells which exhibit most manifold variations within comparatively narrow limits.

History and Nomenclature.—Aristotle included bivalves among other shelled forms of very diverse structure in his great group of hard-skinned animals or Ostracodermata. Linnaeus was content to refer them to an equally heterogeneous group of worms. Cuvier defined them more exactly as a subdivision of molluscs, and gave them the title of headless (Acephala), which they still frequently receive. To Owen is due the designation Lamellibranchiata, which refers to the plate-like character of their gills, and it is by this title that they are now generally known. The term Lipocephala is a yet more modern one referring to the undeveloped nature of the head, and the absence of the rasping tongue which is found in other molluscs (Glossophora). Bivalve shells are exhibited by other animals besides Lamellibranchs, and especially by the small class of lamp-shells or Brachiopods, but in the latter the structure of the animal is not in any sense that of a mollusc, and the position of the valves is ventral and dorsal, instead of lateral. The Brachiopods are therefore excluded from this article, in which the title bivalve is regarded as equivalent to Lamellibranch.

Structure.—(a) The body of the bivalve can usually be split along the middle line into similar halves; it is bilaterally symmetrical. It is usually compressed from side to side, the breadth or thickness being small in proportion to the other dimensions. (b) The ventral surface of the animal—i.e. where the valves gape, is usually produced into a very characteristic ploughshare-shaped

Fig. 1.—Longitudinal Section through a Fresh-water Mussel (after Marshall & Hurst, *Practical Zoology*):

a, edge of mantle; b, foot, with position of ganglion indicated; c, gills; d, mouth; e, tentacles or palps; f, posterior adductor muscle; g, anterior adductor; h, head-ganglion; i, ventricle of heart; j, auricle of heart; k, rectum; l, kidney; m, exhalant aperture; n, inhalant aperture.

muscular organ called the *foot*, which is used in boring and in locomotion, but tends to degenerate in the forms which are most inactive. From a gland frequently present in the posterior part of the foot, a viscid secretion is exuded in the form of threads (byssus) by which the attachment of

the bivalve is effected. (c) From the middle line of the back—i.e. from the hinge of the shell—a flap of skin falls down each side of the body, covering the animal entirely with a double cloak, and closely adhering to the valves of the shell. These two *mantle-skirts* meet one another by their free margins on the ventral side when the shell is shut, but are of course separated when the foot is protruded through the gaping aperture. They are in the closest connection with the shell, which they in fact produce. The shell is an organic growth, and consists of three layers: (a) soft and cuticular, (b) prismatic, and (c) mother-of-pearl. The growth takes place on the internal surface, and at the margin of the mantle. The concentric lines and the modifications of colour remain as indices of the rhythm of growth. In many forms the mantle is drawn out into a pair of lips forming a double tube or siphon. Through this the water, circulated by the gills, passes in and out. Many forms lie buried in the mud with the open ends of the siphons protruded. In Peeten, Lima, and others, the margin of the mantle bears numerous tentacle-like processes. (d) Between each mantle-skirt and the side of the body proper, lie the large and prominent *gills*, which are covered with ciliated cells, causing currents of water which not only purify the blood spread out upon the plates, but whip minute food-particles to the inconspicuous mouth. They are indeed more nutritive than respiratory. (e) There is seldom any marked difference between the head and tail end of the animal; in the middle line in front lies the *mouth*, and the food-canal ends in a similar position behind. The canal itself lies mainly in the plane dividing the body into halves, but exhibits more or less looping in the region of the foot. A large gland (the so-called liver) is situated far forward near the stomach expansion. Still further forward, in the region of the pharynx, there often is a blind pocket containing a curious clear cylinder (the crystalline style), which some regard as the equivalent of the rasper found in other molluscs. Flat tentacles occur on each side of the mouth and look like small gills. They are richly supplied with blood-vessels and nerves. (f) The shell is opened by the action of a passive tendinous band (*ligament*) which lies at the dorsal meeting-place of the two valves, and acts like

a piece of india-rubber squeezed into the hinge-line of a closed door; the shell is shut by one or two great muscles (*adductors*) which run across from valve to valve. There are also muscles, more or less powerful according to habit, for working the foot. The marks made by the insertion of the muscles on the shell are readily seen inside the empty valves. (g) The *accrues system* consists of three chief pairs of ganglia, the anterior cerebral pair being united by connectives to a pair in the foot (*pedal*), and to a posterior pair called

Fig. 2.—Vertical Section through a Fresh-water Mussel:

a, mantle; b, filaments of gills; c, ventricle of heart; d, auricle of heart; e, gut grown round by ventricle

parieto-splanchnic or *visceral*. From these three centres numerous nerves are given off to the body generally. An auditory sac (*otocyst*) is found in close association with the pedal ganglia, and a

patch of smelling or water-testing cells (*osphradium*) occurs at the base of the gills. Though eyes are never present on the reduced head, they sometimes occur in extraordinary abundance (to the number of many hundreds) along the margin of the mantle (e.g. *Pecten*, *Arca*). (h) The heart lies just below the hinge, and consists of a contractile median ventricle driving the blood to the body, and of two auricles symmetrically placed on each side, receiving purified blood from the gills. The ventricle usually grows round the gut, which thus appears to run right through the heart. The whole organ is inclosed in a special portion of the body-cavity known as the pericardium, and this is in indirect communication with the exterior by means of two (i) *kidney-tubes* (nephridia) which lie below the heart, and open externally on the sides of the body. (j) A pair of *reproductive organs* lie in the foot, and their ducts open laterally near the apertures of the kidneys, with which they are occasionally united. The sexes are generally separate, but may be united, and both those forms may occur within one genus (e.g. oyster).

Habit.—The majority of bivalves are marine forms, but not a few occur in fresh water. Between the rapidly swimming *Lima* and *Pecten*, and the entirely quiescent oyster, intermediate degrees of activity and passivity occur, but most decidedly incline towards the extreme illustrated by the oyster. In *Lima* and *Pecten* the valves are opened and shut with great rapidity, and swimming thus effected; in the razor-shell (*Solen*) water is forcibly squirted outwards from within the mantle-cavity, and the animal moves backwards; in the cockle (*Cardium*) the foot is vigorous enough to enable the mollusc to take small jumps; in many cases (*Teredo*, *Pholas*, *Lithodomus*, *Xylophaga*)

Fig. 3.—Several Forms of Bivalves :

A, *Avicula*; B, *Pectunculus*, with extended foot (a) and extended foot (c); C, *Venus*, with respiratory siphons (a, b) and extended foot (c); D, *Mya truncata*, showing respiratory siphons (a, b) and foot (c).

a permanent hole is bored in wood or stone; in the majority the foot is used for a slow creeping progression along the sand. From the nature of the nutrition, by the inwasting currents produced by the gills, it is evident that the food must consist of minute organisms. Algae, Diatoms, Infusorians, minute Crustacea, and the like form the principal diet.

Life-history.—In almost all cases the eggs are fertilised within the mantle-cavity. There they remain for some time sheltered in the gills, or even within special brood-chambers (*Cyclas*). In rare cases (*Galeomma*, *Kellia*) the larvæ issue as such from the genital apertures, but in the vast majority the eggs are developed as above noted within the mantle-cavity. The larvæ very generally enjoy a period of free-swimming life before

settling down, but in some cases even this seems to be suppressed. In the Fresh-water Mussel (q.v.) (*Anodonta*) the larvæ are not liberated by the mother except in the presence of certain fishes such as sticklebacks. On the gills of the latter the larvæ become temporarily parasitic, and undergo very considerable metamorphosis.

Classification.—The Lamellibranchiata are usually classified according to the development of the closing muscles of the shell.

ORDER I.—*Isomya*. Anterior and posterior adductors approximately equal :

Sub-order I.—*Integripallia*, where the line attaching the lower margin of the mantle to the valve is a continuous curve and not inflected—e.g. *Arca*, *Trigonia*, *Unio*, *Anodon*, *Lucina*, *Astarte*, *Tridacna*, *Chama*, *Cardium*, *Cyclas*, *Cyprina*.

Sub-order II.—*Simipallia*, where the line attaching the lower margin of the mantle to the valve is not a continuous curve, but inflected to form a sinus—e.g. *Tapes*, *Venus*, *Tellina*, *Maetra*, *Mya*, *Saxicava*, *Aspergillum*, *Pholas*, *Teredo*.

ORDER II.—*Heteromya*. Anterior adductor decidedly smaller than posterior—e.g. *Mytilus*, *Modiola*, *Lithodomus*, *Mulleria*.

ORDER III.—*Monomya*. No anterior adductor, and no siphons—e.g. *Cardiola*, *Avicula*, *Ostrea*, *Lima*, *Pecten*.

Distribution.—Bivalves are found all over the world, though only a few species like *Mytilus edulis* and *Saxicava arctica* can be described as cosmopolitan. The marine forms occur from the shore level down to great depths, and the same species is not unfrequently found at the most diverse depths. Historically, the bivalves appear in the Cambrian strata, though only to a slight extent. In the Lower Silurian they are still far from numerous, but Barrande enumerates 1100 species from the Upper Silurian of Bohemia alone. The *Heteromya* at first preponderate. From the Upper Silurian onwards, bivalves are exceedingly abundant, and the satisfactory preservation of their shells makes them of great value as index fossils in determining the age of given strata. Among Lamellibranchs occur some of the best instances of types persisting throughout long periods.

Pedigree.—The bivalves must be regarded as a group which has developed along a line entirely different from that of the other molluscs. From an ideal ancestral mollusc like that sketched by Ray Lankester, two lines of progress have been followed. On the one hand, the shell has remained single, the head has not been reduced, the buccal apparatus has developed, and the life has been relatively active. This path has been followed by Gasteropods, Pteropods, and Cephalopods. On the other hand, along the other line, the mantle has become bilobed, the shell double, the gills large, plate-like, and nutritive, the head much reduced, and the life relatively passive. This path has been followed by the Lamellibranchs.

Economic Importance.—Many bivalves (oyster, mussel, cockle, clam, &c.) are used for food. Others are largely utilised as bait in sea-fishing. Pearls and mother-of-pearl are obtained from *Meleagrina* and other forms. The valves of *Placuna* are sometimes used for window-panes. *Venus mercenaria* and other types have been used by savage tribes for coinage. Larger shells are occasionally calcined for lime. The boring bivalves have an important destructive influence on piers and ship timber, but the custom of ensheathing in metal now renders their attack less effectual. See CONCHIOLOGY, MOLLUSCS, OYSTER, &c., and Huxley's *Anatomy of Invertebrated Animals* (Lond. 1877).

Biv'ouac (through Fr. from Ger. *beiwache*: *bei*, 'near,' and *wachen*, 'to watch') is the encampment of soldiers in the open air, without tents, where

every one remains dressed in his place, and with his weapons by him. It has always been necessary for opposing armies thus to pass the night before a battle; but the French revolutionary armies first introduced the practice of dispensing with tents throughout the campaign, thus greatly lessening their baggage-trains and increasing the celerity of their movements. No European army now carries tents for its combatant troops. At a distance from the enemy they are cantoned (see BILLETING) in the villages on the line of march. When an engagement is imminent they bivouac. Each battalion, or other unit, has its allotted space, in the centre of which the arms are piled in quarter column. Round the piles of arms each company has its sleeping-ground marked out. A bivouac would, if possible, be placed under the shelter of trees, or so as to be protected from wind by hedges. Improvised screens of straw, heather, &c. would be used, and large fires lighted. But the health of troops always suffers if bivouacked constantly in bad weather. In India and other hot countries it is found necessary to carry tents still, and the bivouac is never resorted to if it can be avoided.

Bixa. See ANNATTO.

Bizerta, or BENZERTA, a fortified seaport of Tunis, at the head of a bay of the Mediterranean, and at the mouth of a lagoon, united to the bay by a narrow channel. It is the most northerly town in Africa, being 38 miles NW. of Tunis. Its port, formerly one of the best in the Mediterranean, has again been deepened, provided with breakwaters, and made a great French naval station. The tunny, mullet, and coral fisheries are very productive. Pop. about 16,000.—The ancient *Hippo Darrhytus* or *Zardus*, Bizerta was founded by the Tyrians, was fortified by Agathoeles in 397 B.C., and under the Romans was a free city. Since 1881 it has been held by the French.

Bizet, GEORGES, a French composer, was born 25th October 1838 at Paris, and studied at the Conservatoire under Halévy, and in Italy. His earlier operas, *Les Pêcheurs de Perles* (1863), *La Jolie Fille de Perth* (1867), showed Wagnerian sympathies but had little success; but his music to Daudet's *L'Arlesienne* was popular, and his comic opera *Carmen* (1875) was not more remarkable for its originality and dramatic effectiveness than for its success. He had just begun to taste the sweets of popularity when on 3d June 1875 he died. See LIVES by Pigot (1889) and Bellaigue (1891).

Biziura. See MUSK DUCK.

Bjela, a town in the Russian-Polish government of Siedlee, on the Krzna River, has a palace of the Radziwill princes, and a trade in corn and garden produce. Pop. 9975.

Björnson, BJORNSTJERNE, a celebrated Norwegian writer, was born 8th December 1832, at Kvikne, in Osterdalen, where his father was pastor. After studying at the university of Christiania from 1852, and then for a year at Copenhagen, he returned to Norway in 1857, and published his beautiful tale *Synnøve Solbakken*, which at once attracted universal attention, and is still regarded as having marked an epoch in the recent literature of Norway. Immediately afterwards he was appointed manager of the Bergen Theatre by its proprietor Ole Bull, and in 1858 he published the tale *Arne* and the drama *Hulde-Hulda*. In 1859 he left Bergen to be editor of the newspaper *Aftenbladet* at Christiania, but his stay there was cut short by the violent controversies in which he soon became involved; and in consequence he withdrew the next year to Copenhagen, where he collected a number of his shorter tales, and

brought them out, together with the drama *Mellem Slagene*, under the title of *Smaastykker*. From 1860 to 1862 he lived in Rome, where he wrote several lyrical poems, the drama *Kong Sverre* (1861), and the trilogy *Sigurd Slembe* (1862); and on his return to Norway in 1863 the Storting awarded him a yearly pension. In the next two years he produced two plays, *Marie Stuart in Skotland* and *De Nygifte*, for the theatre at Christiania, of which he was director from 1865 to 1867, at the same time editing the *Norsk Folkeblad*; but, resigning these appointments in 1867, he again lived abroad from 1872 to 1876, when he returned to Norway, and settled for some years in the country near Lillehammer. Björnson held the highest place in popular favour as a political orator, and took an active part in the movement which led to the victory of parliamentary government in Norway. Though he lived in Paris in 1883-88, he still made his influence felt in Norwegian politics as a leader of the 'Peasants' Party.' Björnson has also written the tales *En Glud Gut* (1860), *Jernbønen og Kirkegaarden* (1866), *Fiskerjenten* (1868), *Brudeslaatten* (1872), *Magnhild* (1877), *Kaptein Mansona* (1879), and *Det flager i Egen og paa Huene* (1884); the plays *Sigurd Jorsalfar* (1872), *En Fallit* and *Reluktøren* (1875), *Kongen* (1877), *Leonardi* and *Det nye System* (1879), *En Hamske* and *Over Æne* (1882); a volume of *Digte og Sange* (new ed. 1880); and numerous pamphlets on political and religious questions of the day. A number of his tales have been translated into English and German, and several of his plays have secured a footing on the German stage. Both as a poet and a novelist Björnson stands in the first rank among living Scandinavian writers. Some of his songs are among the chief favourites of his countrymen; and his tales, which have been compared to the old sagas for their terse and vigorous diction, are strikingly vivid pictures of Norwegian peasant-life. See Brandes, *Björnson og Ibsen* (Copenhagen, 1882).

Björnstjerna, MAGNUS, COUNT, a Swedish Liberal statesman, born in 1779, in 1809 was sent on a secret embassy to Napoleon, in 1813 fought at Leipzig, and subsequently in Holstein and in Norway, where in 1814 he concluded the treaty that united that country with Sweden. In 1826 he received the title of count; and from 1828 till 1846 was ambassador to Great Britain. He died at Stockholm, 6th October 1847. Besides some political writings, he published a work on the Hindu Theogony (1843).

Black may be considered as the negation of colour, resulting from the absorption of the rays of light by certain substances. Painters produce it approximately by an unequal combination of red, blue, and yellow (see COLOUR; also DYEING). In medieval art, black was symbolical of evil, error, and woe; and is still a usual funeral colour (see FUNERAL RITES). For its use in Heraldry, see HERALDRY, HATCHMENT.

BLACK PIGMENTS, used in painting, are derived principally from animal and vegetable substances. The most important are: *Lamp-black*.—The finer kinds are prepared from the soot of burnt resin or resinous woods. The coarser varieties are made from the soot of an oil obtained from gas-tar and other cheap bodies. This black is much used by painters, and it is also employed for making printing ink.—*Blue-black* consists of levigated charcoal from vine twigs. It is also a very serviceable black for artistic work.—*Bone-black* and *Ivory-black*, as their names imply, are simply animal charcoal, and consequently possess the power of absorbing colour from animal and vegetable solutions. Therefore they cannot be safely mixed with other organic

colours in water-colour painting. The above pigments are, of course, prepared either with oil or gum, according as they are to be used in oil or water-colour work.—*Indian Ink* (q.v.) is a black prepared from a vegetable carbon, and so far resembles lamp-black, but it is not very suitable for mixing with other colours. For black dyes, see DYEING.

Black, ADAM, publisher, was born in Edinburgh, 20th February 1784, and, trained as a bookseller there and for two years in London, he with a nephew established the Edinburgh business of Adam and Charles Black. The two enterprises which, above all else, gave position, fortune, and success to the firm, were the purchase of the copyright of the *Encyclopædia Britannica* in 1827 after Constable's failure; and that of Scott's novels from Cadell's representatives in 1851 for £27,000. A seventh and eighth edition of the *Britannica* was issued during Black's business connection with the firm, while Scott's novels had a large and steady sale. Black was long a prominent and useful citizen of Edinburgh; was twice Lord Provost; and was Liberal M.P. for Edinburgh (1856–65). He died 24th January 1874. A statue was erected in Edinburgh in recognition of his services in 1877. See *Memoirs* by Nicolson (1885).

Black, JOHN, journalist, was born near Duns, Berwickshire, in 1783. Left an orphan ere he had reached his twelfth year, Black, after filling posts in the offices of a Duns writer and an Edinburgh accountant, in 1810 went up to London, and was engaged as a parliamentary reporter for the *Morning Chronicle*, of which from 1817 he assumed the editorship. Under him the paper was celebrated for its independence and fearless advocacy of progress—a fearlessness which led to his duel with Roebuck in 1835. Charles Dickens was one of his reporters and contributors, and James Mill helped him with almost daily advice. John Stuart Mill has described him as 'the first journalist who carried criticism and the spirit of reform into the details of English institutions.' He retired from the editorship in 1843; an annuity of £150 a year was bought for him by his friends; and, until his death on 15th June 1855, he lived in a pleasant cottage at Snodland, near Maidstone. Black was author of a *Life of Tusso* (1810), and the translator of works from the German, French, and Italian.

Black, JOSEPH, an eminent chemist, was born in 1728, at Bordeaux, where his father was engaged in the wine-trade. Both his parents were of Scotch descent, but natives of Belfast, to which city their son was sent for his education in 1740. In 1746 he entered the university of Glasgow, and studied chemistry under Dr Cullen. In 1751 he went to Edinburgh to complete his medical course, and in 1754 took his degree. In his famous graduation thesis (1756) he showed that the causticity of lime and the alkalies is due to the absence of the carbonic acid present in limestone and in what are now called the carbonates of the alkalies. To this he gave the name 'fixed air,' which gave way before that of 'carbonic acid,' first used by Lavoisier in 1784. The book was a distinct contribution to chemical science, and by Brougham and Robison is placed second only to Newton's *Optics* as a model for scientific investigation. Black pointed out the path afterwards followed by Cavendish, Priestley, and Lavoisier. On the removal of Cullen in 1756 to Edinburgh, Black succeeded him as professor of Anatomy and Chemistry in Glasgow, but soon after exchanged duties with the professor of the Institutes of Medicine, and lectured on the subject for ten years, practising the while as a busy physician, yet finding time for original investigation.

Between 1756 and 1761 he evolved that theory of 'latent heat' on which his scientific fame chiefly rests, and which formed the immediate preliminary to the next great stride in discovery by his pupil and assistant, James Watt. In 1766 he succeeded Cullen in the chair of Medicine and Chemistry in Edinburgh, and henceforward he devoted himself chiefly to the elaboration of his lectures, in which he aimed at the utmost degree of perspicuity, and with perfect success. His class became one of the most popular in the university; it occasioned, however, some disappointment that one so capable of enlarging its territory made no further contributions to chemistry. Though of an extremely delicate constitution, he prolonged his life, by care and temperance, to the age of seventy-one. He died on December 6, 1799. His lectures were published in 1803 (2 vols. Edin.), edited by Professor Robison.

Black, WILLIAM, novelist, was born in 1841 in Glasgow, where he received his education, and studied art at a government school with the view of becoming a landscape-painter. Instead, however, he adopted journalism, having written for the *Glasgow Weekly Citizen* prior to his removal to London in 1864. During the Prusso-Austrian war of 1866 he was employed as special war correspondent on the staff of the *Morning Star*; and in a novel, *Love or Marriage* (1868), he utilised some of his experiences. In *Silk Attire* (1869) and *Kilmeny* (1870) proved more successful than the previous work; but it was *A Daughter of Heth* (1871) that established his reputation with the novel-reading public. The *Strange Adventures of a Phaeton* (1872) is founded on an actual driving excursion between London and Edinburgh. *A Princess of Thule* (1873) is the best perhaps of all his romances, with its vivid transcripts of Hebridean scenery, its quaint Gaelic-English, above all, its exquisite heroine. Among its successors are: *Three Feathers* (1875); *Madeup Violet* (1876); *Green Pastures and Piccadilly* (1877); *Macleod of Dare* (1878); *White Wings* (1880); *Sunrise, a Story of these Times* (1880); *Shandon Bells* (1882); *Yolande* (1883); *Judith Shakespeare* (1884), with Shakespeare himself for one of the characters; *White Heather* (1886); *Sabina Zembra* (1887); *In Far Lochaber and The Strange Adventures of a House Boat* (1888); *The Penance of John Logan* (1889); *New Prince Fortunatus* (1890); *Stand Fast, Craig Royston* (1890); *Wolfenberg* (1892); *Handsome Humes* (1893); *Highland Cousins* (1894); *Briseis* (1896); *Wild Eclis* (1898). Assistant-editor for five years of the *Daily News*, Mr Black in 1874 abandoned journalism. He died 10th December 1898.

Black Acts are a collection of the acts of the Scottish parliament from 1424 to 1594, so called because printed in Black-letter (q.v.). The name was also given to an act of George I. (1723) affecting poachers who disguised their faces in black for the purpose of committing outrages (referred to in White's *Natural History of Selborne*).

Black Art. See MAGIC.

Black Assize, the popular name commemorative of an extraordinary and fatal pestilence which broke out at Oxford at the close of the assizes, July 6, 1577. It was popularly interpreted as a divine judgment on the cruelty of a sentence passed by the court. From the 6th of July to the 12th of August, 300 persons in Oxford and the neighbourhood are said to have died of this terrible malady, among whom were the chief officials who sat on the assize, most of the jury, and many members of the university. Women, poor people, physicians, visitors, and children are said to have escaped the infection. A similar event is recorded as having taken place at Cambridge at the Lent Assizes in 1521.

Black-band Ironstone is an ore of iron found very extensively in Scotland and elsewhere. It occurs in the Carboniferous system in regular bands or layers, and is generally associated with coal and limestone. It is mainly a carbonate of iron with much coaly matter. The black-band ironstone is easily reduced. It does not, however, yield a first-class iron when smelted by itself, and is therefore generally mixed with a small quantity of hematite (red iron ore), which communicates strength and hardness to the iron obtained.

Black Beer. See SPRUCE BEER.

Black Beetle, at once a popular and a scientific term—popular when applied widely to all sorts of forms, from Blaps (q.v.) to the Cockroach (q.v.), which is not a beetle at all; scientific when restricted to a great family of beetles known as Melanosomata in the Heteromera sub-order of Coleoptera. The possible extent of the term will be evident when it is noted that even when restricted to these Melanosomata, it may be applied to 600 genera and about 4500 species. These Melanosomata (Gr., 'black-bodied') have short strong upper jaws, the eyes to the sides, the feelers usually with 11 joints, the uppermost joints of the legs almost always separate (the anterior pair spherical and sunk in sockets, the posterior lying transversely), the wing-covers often fused, and in these cases without wings, the abdomen with five free joints. They love dark damp places, though a few less dismally coloured, for the prevalent black is sometimes relieved, get out into the open. They mostly have a bad smell. The larvae are very long and narrow. The familiar Blaps, the Bolitophagus of fungus, the very abundant Hypopheus, living under the bark of old trees, the Tenebrio, with its larva the Meal-worm, so much used in feeding birds, are some of the commonest genera of Melanosomata or black beetles.

Blackberry. See BRAMBLE.

Blackbird, or MERLE (*Turdus merula* or *Merula vulgaris*), a well-known species of Thrush (q.v.), common in all parts of Britain, and throughout Europe generally; found also in the north of Africa, and in the Azores. In Asia, it gives place to a closely allied species, *Turdus pacificus*. In size, the blackbird is intermediate between the

evergreens or shrubs; and when disturbed, takes wing with a vociferous chattering of alarm, seeking refuge in some neighbouring thicket. Its food consists of worms, snails, insects, berries, seeds, &c. Its fondness for fruit makes it often annoying to the gardener; but probably it would in general be better to protect cherries and pears by nets than to shoot the bird, which is of great use as a destroyer of insect larvae. Like some of the other thrushes, it also devours (especially in winter) great numbers of small snails, dexterously breaking the shell against a stone. When searching for food, it jumps about with characteristic alacrity; when disturbed, it flies off with a somewhat magpie-like chuckle; its familiar flight along the hedges is 'wavering and fitful,' and in the breeding-season the female especially moves by a succession of starts. It is not usually a gregarious bird, although great flocks sometimes appear upon the British coasts in winter, on their passage from more northerly to more southerly countries. Otherwise, the blackbird is not in Britain a bird of passage. It pairs very early in spring; the male and female are indeed very often seen together during winter; it builds its nest early, and generally has two broods in the year. The nest is usually placed in some thick bush; it is of ruder workmanship than that of the song-thrush, which, however, it resembles, and is usually formed of strong stems of grass, with a finer lining of dry grass inside, and a massive plastering of clay outside. The inside and outside of the nest are kept very clean, and a male has been seen to remove the dropping of a young bird from the vicinity of the nest. The male aids in the work of feeding the young. The eggs are four or five in number, of a pale blue colour, generally speckled with brown. A female blackbird and a male thrush have been known to pair. The voice of the blackbird is very powerful, and its song more mellow than that of the thrush, but with 'much less variety, compass, or execution.' The blackbird is often kept as a cage-bird, and would be much more frequently so, but for the too great loudness of its song; it is readily trained, exhibits considerable powers of imitation, and has even been taught to articulate.—The Ring Ouzel (q.v.), sometimes called the Ring Blackbird, is a nearly related species (*T. torquatus*).—The Crow, the Redwing, and other blackbirds of America are entirely different.—The Savanna Blackbird of the West Indies is also of a different family. See CROTOPHAGA.

Black Book, an interesting collection of English Admiralty Law in the 14th century, first edited by Sir Travers Twiss (4 vols. 1871-76). It indicates the pretensions of the civil law as regards trial without jury, torture, &c., which afterwards led to legislation in vindication of the position of the Common Law courts.—BLACK BOOK is also a usual term for the reports presented to parliament in 1536, on which the legislation for the dissolution of the monasteries and the secularising of their revenues proceeded. These reports probably never existed as a book (fabled to have been burnt in Queen Mary's reign); such of them as remain are to a large extent extravagant and malicious accusations without any evidence (see *Letters and Papers of the Reign of Henry VIII.*, edited by James Gairdner, vol. x. 1888; F. A. Gasquet, *Henry VIII. and the English Monasteries* (2 vols. 1888-89).—A list of habitual criminals, first published in 1877, has been also so called.

Black-bully, BALLY-TREE WOOD, or SAPODILLA PLUM (*Sapota Müllerii* or *Achras Sapota*), a South American tree, belonging to the Sapotaceae. Its wood, which is greenish and very durable, is used for shipbuilding. The bark is febrifugal,

Blackbird.

missel-thrush and the song-thrush or mavis. The plumage of the adult male is wholly of a deep black colour, the bill and orbits of the eyes yellow; the female and the young are dark brown above, paler on the throat, and rusty brown on the breast, with brown bill, yellow, however, in spring-time. Very old blackbirds have the feathers on the back of the neck tipped with fine hairs. White, cream-coloured, and other variations occasionally occur. The blackbird frequents hedges, thickets, and woods; is shy, restless, and vigilant, keeping much under cover of

whilst the seeds are diuretic and aperient. The inspissated milky juice is largely imported from Berberce as gutta-percha.

Blackburn. a town of Lancashire, 21 miles NNW. of Manchester, and 9 E. of Preston. It stands on a stream from which it appears to derive its name, a branch of the Ribble. The surrounding district, formerly known as *Blackburnshire*, or *Blagbomshire*, was long very wild and dreary, but now is densely populous. Coal was formerly plentiful, and lime still abounds in it. Blackburn had acquired some importance as a market-town in the 16th century. Its manufacturing prosperity can be traced back at least to the middle of the 17th century, when it was noted for the production of a kind of linsey-woolsey known by the name of *Blackburn Checks*, afterwards superseded by the *Blackburn Grays*, so called from their being printed unbleached. In the course of the 18th century the cotton manufacture became the chief industry of the town, which is now the largest and most important cotton manufacturing town in the world, the number of cotton-factories being very great, and many of them employing from 1000 to 2000 operatives. Great improvements in machinery for the cotton manufacture have been made in Blackburn, among which the first place in importance as well as in date must be assigned to the invention of the spinning-jenny by James Hargreaves (q.v.), a native of the town, in 1767. His invention, however, was regarded with so much dislike, that he was compelled to remove from the town, and it was not till the beginning of the 19th century that it came into general use. The growing importance of Blackburn is seen best in the increase of its population from 36,629 in 1831 to 63,126 in 1861, to 104,014 in 1881, and to 120,064 at the census of 1891. The chief public buildings are the town-hall (1856), an Italian edifice built at a cost of £30,000, the Gothic exchange (1865), the infirmary (1862), and St Mary's Church, of very ancient foundation, but almost entirely rebuilt (1826-57). There is a corporation park of 50 acres, part of which is 700 feet above sea-level, and commands a wide view; a new Queen's Park of 35 acres was opened on Jubilee day, 1887. The grammar-school was established by Queen Elizabeth in 1567; in 1888 the Prince of Wales laid the foundation-stone of the technical school. Blackburn has returned two members since 1832; and it received its municipal charter in 1851. See Abram's *History of Blackburn* (1878).

Blackburne, FRANCIS, Lord Chancellor of Ireland, was born at Great Footstown, County Meath, 11th November 1782, and in 1798 entered Trinity College, Dublin. Called to the English bar in 1805, to the Irish in 1822, he was appointed Attorney-general for Ireland in 1830 and again in 1841, Master of the Rolls in 1842, Chief-justice of the Queen's Bench in 1846, and Lord Chancellor of Ireland in 1852 and 1866. He thus served under both Whig and Tory governments, and was brought into close connection with the leading politicians on either side; whilst at different times he had the duties imposed on him of prosecuting O'Connell, and judging Smith O'Brien. In 1867 he declined an offer of a baronetcy, and for some years he was Vice-chancellor of Dublin University. He died 17th September 1867. See the Life by his son (1874).

Black Canons. See AUGUSTINIANS.

Black Cap, the cap worn by English judges as a part of full dress, and so put on by them when a prisoner is condemned to death.

Blackcap. BLACKCAP WARBLER, or BLACKCAP FAUVETTE (*Sylvia atricapilla*), a bird of the great family of the Sylviadæ, or Warblers. It is regarded as the sweetest song-bird in Britain, or

indeed in Europe, except the nightingale, to which it is said to be even superior in 'its shake or trilling note.' Very often, however, the strain is desultory, and of short continuance; but it is loud, rich in tone, and has a 'great variety of sweet and gentle modulations.' The song is especially joyous during and after rain. White says, in his *Natural History of Selborne*, that while the Blackcap warbles, its throat is wonderfully distended. It is a rather smaller bird than the nightingale; the female is larger than the male. The general colour is gray,

Blackcap (*Sylvia atricapilla*).

with an olive tinge above, and becoming white below. The upper part of the head in the male is jet-black; in the female, of a rusty-brown colour. The feathers of the head, both in the male and female, are somewhat erected, giving the bird a hooded appearance, on account of which it is called, in Germany, 'the monk.' In Britain, the Blackcap is only a bird of passage, arriving early in spring, and retiring in September. It is most frequent in the southern counties of England, but is found even in Scotland; on the Continent, it extends its migrations as far north as Lapland. In the south of Europe, it is found both in summer and winter, and especially frequents bushy places. Its beautiful song, sometimes spoilt by successful mimicking, and its lively affectionate habits, make it a favourite captive. See WARBLER.

Blackcap Titmouse, or CHICKADEE, a North American bird. The Marsh Titmouse, a British bird, is sometimes called Blackcap, or Blackcap Titmouse. See CHICKADEE and TITMOUSE.

Black Chalk. See CHALK, BLACK.

Blackcock, HEATH-FOWL, or BLACK GROUSE (*Tetrao tetrix*), a species of Grouse (q.v.), abundant in Britain wherever there are moors of considerable extent, and more particularly where there are bogs and morasses with rank herbage, or, adjacent to the moors, natural woods or young plantations of pine and fir. Comparatively rare in the south of England, the blackcock becomes more common towards the north, and is very plentiful in the mountainous parts of Scotland. It is found in some of the Hebrides, but not in the Orkney or Shetland Isles. The only other British species, the Capercaillie (q.v.) or Wood-grouse, became some time ago virtually extinct in Britain, but the noble bird has now been reinstated. On the continent of Europe it occurs both in mountainous and marshy countries, as on the Alps and in Holland; it is found as far south as the Apennines, and as far north as the forests of Lapland; it abounds in most parts of Scandinavia, where it is carefully protected, the males only being killed, but these in great numbers for the London market; it is diffused over almost all parts of Russia, and is found in Siberia. Its range is restricted to the

Eurasian continent. The male is much larger than the female, sometimes weighing as much as 4 lb., while the female weighs only about 2 lb. They also differ very much in plumage. The male is of a shining bluish-black colour, with a conspicuous white bar on the wings below the ends of the great wing-coverts, and a mixture of black and white on the legs; there is a piece of bare scarlet skin above the eye; the outer feathers on either side of the tail are elongated and curve outwards, giving it a very peculiar appearance. The female, called the *Gray Hen*, is of a rusty-brown colour, darkest on the

Blackcock (Male and Female).

upper parts, everywhere barred and mottled with a darker colour; the tail is straight and only slightly forked at the end. The young males resemble the females in plumage. The shank in this species is feathered, but not the toes. The flight, though heavy, is strong and rapid, and the birds can also run with much agility. It is a gregarious bird, but in winter the sexes generally keep in separate flocks. In spring the males resort to elevated and open spots, where they crow, and also make a sound which has been likened to the whetting of a scythe, thus inviting the females to repair to them; they strut and trail their wings like turkey-cocks, and fierce contests often take place among them. They are polygamous, and pay no attention to the females during incubation, nor do they take any part in rearing the young. The nest is of the simplest construction, a few straws or the like, placed together among tall heath, or under the shelter of a low thick bush. The eggs, six to eight in number, are yellowish-white, speckled with orange-brown, and about 2 inches long. The usual food consists of the seeds of rushes and other plants, berries, insects, worms, the tender shoots of heath, leaves, &c. But the blackcock sometimes visits cornfields and stubbles to feed on corn, is frequently to be found in turnip-fields near plantations in hilly districts, and, at least in winter, eats the young shoots of pines, firs, birches, and alders. It is highly esteemed for the table. The shooting season is from 20th August to 10th December.

Hybrids between different species of grouse, and even between grouse and pheasant, are said to exist, but not much reliable information is available. Thus it is probable that the bird called *Tetrao hybridus* or *medius*, sometimes found in the Scandinavian peninsula and other parts of Europe, is a hybrid between the Black Grouse and the Capercaillie, *Tetrao urogallus* (q.v.). The Ptarmigan (q.v.) or Brown Grouse are nearly allied.

Black Death is one of the names given to a fearful epidemic which desolated the world from China to Ireland in the 14th century. It raged in England and the rest of Europe in 1348-49, again in 1361-62, and in 1369; and at the time was usually called in England the 'Pestilence' or the 'Great Pestilence.' It is now believed to have been a specially severe visitation of the oriental plague (see **PLAGUE**), with some special symptoms, mainly boils or buboes on the thighs and arms, and putrid inflammation of the lungs, with vomiting of blood. Its black spots (whence the name) and tumours were the seals of a doom that medicine had no power to avert. In most cases the victims died in two or three days, and sometimes the very day they were stricken.

The pestilence seems to have originated in China, and is said to have been preceded, if not, as was believed, in some measure caused, by strange convulsions of nature—earthquakes, droughts, famines, floods, and swarms of locusts; while its westward course was accompanied by dense and awful fogs, and an apparent inversion of the order of the seasons. There had been a visitation of the ordinary plague in 1342; but it was in 1348 that Europe was terrified by the approach of a wholly unparalleled scourge. In China 13,000,000 were reported to have perished, and 24,000,000 elsewhere in the East. By the northern coast of the Black Sea and Constantinople, the contagion reached the seaports of Italy and Southern France, whence Germany and England were infected. The first English victims succumbed in Dorsetshire in August 1348; but it was not till winter that it reached London by way of Gloucester and Oxford. The havoc was almost incredible, but is well attested. Towns were stripped of their inhabitants; religious houses lost nine-tenths of the inmates. In London 100,000 died, 50,000 being buried in a plot of ground now covered by Smithfield; and Norwich mourned 60,000 deaths. Careful investigators have come to the conclusion that the victims of this one visitation must have comprised one-third if not one-half of the total population of England, which is estimated to have then been from 3,000,000 to 5,000,000 in all. For a time Scotland enjoyed immunity, and spoke of the 'foul death of the English;' but ere long, like Ireland, it was also severely visited.

The mortality caused by the plague was only one startling consequence. Religious excitement led to extravagances of fanaticism, especially in Germany, to that of the Flagellants (q.v.); all natural bonds of human society were loosened, so that friend deserted friend and mothers fled from their stricken children, and the demoralisation showed itself in many cases in reckless debauchery. Elsewhere perverted Christian zeal led to frightful persecutions of the Jews, as at Mayence, where 12,000 Hebrews were believed to have been massacred.

But it is only in modern times that the extent of the economic and social consequences of this plague has been fully understood; the black death forms a great economic turning-point in English history. The dearth of labourers caused wages in England to be nearly doubled; law after law was passed to prevent the inevitable rise in the payment of labour; and the ill-feeling thus engendered between landholder and tiller of the soil led to numerous social changes and the rebellion of Wat Tyler. Old methods of culture disappeared; farms on lease largely took the place of great estates managed by bailiffs.

The great pestilence is referred to by Chaucer and Langland; Boccaccio's *Decamerion* gives a singularly vivid view of its ravages in Florence;

but see the article **PLAGUE** in Vol. VIII.; Hecker's *Epidemics in the Middle Ages* (1843); Creighton's *History of Epidemics in Britain* (1892); Jessopp's *Coming of the Friars* (1888); works by Thorold Rogers, Cunningham, Denton (for the economic aspects), and (for subject as a whole) F. Aidan Gasquet, *The Great Pestilence* (1894).

Black Draught. See **MAGNESIUM**, **SENNA**.

Black Earth (*Tchernozem* of Russian geologists) is the name given to a deposit which covers vast areas in South Russia, extending over the steppes and low-lying plateaus that border on the Black Sea, and the depressed area to the north of the Caspian, with a breadth from north to south of from 200 or 300 to nearly 700 miles. It closely resembles the Löss (q.v.) of Central Europe in texture and structure, for it is fine grained, and is usually devoid of stratification. It varies in colour, however, from dark brown to black, and in thickness from a foot or two up to 6 or 7 yards, occasionally reaching, it is said, even to 60 feet. It is composed chiefly of siliceous sand (about 70 per cent.), alumina and other ingredients (23 per cent.), and organic matter (about 7 per cent.). But the composition is variable, the organic matter sometimes exceeding 10 per cent. It appears to be unfossiliferous. It bears the same relation to the glacial accumulations of Russia that the löss of the Rhine, the Danube, &c. does to those of Central Europe, and is probably the fine-grained silt derived from the torrents and flooded rivers that escaped from the melting snows and glaciers of the glacial period. According to some geologists, however, it may owe its origin to the action of the wind. It is supposed by them to be simply an accumulation of wind-blown dust—the finely sifted material being fixed by the abundant grasses of those steppe regions.

Black Eye. See **BRUISE**.

Blackfeet Indians, a tribe of friendly aborigines, generally Roman Catholic, now living in Montana and British America. Those in the United States number about 7200.

Black-fish (*Centrolophus pompilus*), a bony fish of the family Stromateidae, in the division with spinous rays (Acanthopterygii). It is nearly allied to the beautiful *Coryphæna* (q.v.), so frequently called dolphins. Though found in the Mediterranean, on the western coasts of Europe, and occasionally on the southern coasts of Britain, it is everywhere rare, perhaps because it is an inhabitant chiefly of deep waters. It is known to attain a length of more than 30 inches, and a weight of 14 lb. The general form is not unlike that of a perch; there is a single elongated dorsal fin with short rays; the dentition is very feeble; the body is covered with minute scales; the skin is tough and can be stripped off like that of an eel; there is no air-bladder. The colour is black, that of the fins intensely so. It is remarkable for great strength and velocity, and as an article of food is described as delicious. Another British species (*C. britannicus*) is also recorded, and the genus *Stromateus* is closely allied. The name is locally given to various species of fish, and even to small whales and dolphins.

Black Flux is prepared by heating in a covered crucible ordinary or crude cream of tartar, the bitartrate of potash, $\text{KHC}_4\text{H}_4\text{O}_6$, when the tartaric acid, $\text{H}_2\text{C}_4\text{H}_4\text{O}_6$, is decomposed, and charred, forming carbonic acid, CO_2 , which remains in combination with the potash as carbonate of potash, K_2CO_3 , accompanied by much free carbon. This very intimate mixture of carbonate of potash and carbon, otherwise called black flux, is a fine black powder of great service in the fluxing of metallic ores, as of Lead (q.v.), and the separa-

tion of the metal therefrom. In the preparation of black flux it is usual to add to the cream of tartar half its weight of nitre, while *white flux* is produced when twice its weight of nitre is used. The black flux is likewise employed as the raw material from which, on the application of heat in iron vessels, the metal potassium can be obtained.

Black Forest (Ger. *Schwarzwald*), a wooded mountain-chain in Baden and Württemberg, running parallel with the course of the Rhine after its great bend near Basel, and often only a few miles distant from it. The Rhine also bounds it on the south, and the level country between the Enz and the confluence of the Neckar with the Rhine borders it on the north. The chief rivers rising in the Black Forest are the Danube, Neckar, Murg, Kinzig, Elz, Enz, and Wiessen. Of these, the valley of the Kinzig divides the southern and loftier portion from the northern district. The chain attains its greatest elevation in the bare and round-topped Feldberg (4903 feet high), above celebrated Höllenthal, a narrow valley known in connection with Moreau's retreat in 1796. The great mass called the Kaiserstuhl (Emperor's Chair), situated near Breisach, is quite isolated. As to the geological character of the mountains, primitive granite and gneiss form their core, porphyry occurs on their sides, and sandstone in the north and east. Silver, copper, cobalt, lead, and iron are found in greater or less quantity in the principal chain, which is luxuriantly wooded, its name Schwarzwald being derived from the dark-tinted foliage and immense number of its fir-trees. The district is also rich in mineral waters—e.g. the baths of Baden-Baden (q.v.) and Wildbad (q.v.). On the Rhine side the descent is precipitous, but towards the Danube and the Neckar it is gradual. Among its numerous valleys, the Murgthal is the most famous for its natural beauties; but, indeed, the whole of the country is here rich in picturesque scenery, genmed with cascades and deep mountain-lakes, around which cluster the legends of many centuries. The climate is healthy, but severe, although the western slopes are studded with vineyards. Summer rye, oats, and potatoes are cultivated in some parts, but with difficulty, the rearing of cattle being attended with much greater success. This, and the manufacture of articles of wood, forms the chief industry of the inhabitants. The making of wooden clocks and other kinds of timepieces employs about 40,000 persons; and not less than 600,000 articles of this kind, including musical boxes, are exported annually to all parts of the world. A railway starting from Pforzheim makes the complete circuit of the mountains, which are now crossed by a line from Offenburg to Singen, and by numerous shorter lines. The Black Forest railways have been difficult engineering enterprises. The line between Freiburg and Neustadt rises 2000 feet in 22 miles, and at some parts has rails on the rack system. See Seguin's *Black Forest, its People and Legends* (2d ed. 1886).

Black Friars. See **DOMINICANS**. The old Dominican monastery in London, dating from 1276, stood near the north end of Blackfriars Bridge.

Black Friday is a name given to the 11th May 1866, from a commercial panic then at its height, caused by the stoppage of Overend, Gurney, & Co., London.

Black Guard is a term used in the 16th century for the lowest menials of a noble house, the scullions who cleaned pots and pans. It was also used of the hangers-on of an army, camp-followers, then a rabble, vagabonds.

Black Gum. See **TUPELO**.

Black Hawk, a famous chief of the Sac and Fox Indians, born in 1767. He joined the British in 1812, and opposing the removal west of his tribe, fought against the United States in 1831-32. He died in 1838. There are Lives by Patterson (1834) and Snelling.

Blackheath, a high-lying open common in the county of Kent, 7 miles S.E. of London, near Greenwich Park. It commands a fine view, and is a healthy tract, though now not more than 70 acres in extent, many villas having encroached upon its margin. It is a favourite holiday resort for Londoners. The Roman road to Dover crossed it. Blackheath was the first place in England where the ancient Scottish game of golf was introduced, most likely in 1608. On it stands Morden College, founded in 1695 by Sir John Morden for decayed Turkey merchants. Of schools innumerable, the chief is the Proprietary, established in 1830. Blackheath was formerly the scene of several insurrections, including those of Wat Tyler (1381), of Jack Cade (1450), and of the Cornishmen under Lord Audley (1497). Here, too, the Danes encamped in 1011; the Londoners welcomed Henry V. from Agincourt; and Charles II. on his way from Dover met the army of the Restoration. Blackheath was also a noted place for highwaymen. See Dr Drake's *History of Blackheath* (1886).

Black Hole, an appellation familiarly given to a dungeon or dark cell in a prison, and associated in the public mind with a horrible catastrophe in the history of British India—viz. the cruel confinement of a party of English in the military prison of Fort William, since called the 'Black Hole of Calcutta,' on the night of 19th June 1756. The garrison of the fort connected with the English factory at Calcutta having been captured by Suraja Dowlah (Sirāj-ud-Daula), the nawab of Bengal, he caused the whole of the prisoners taken, 146 in number, to be confined in an apartment 18 feet square. This cell had only two small windows, and these were obstructed by a veranda. The crush of the unhappy sufferers was dreadful; and after a night of excruciating agony from pressure, heat, thirst, and want of air, there were in the morning only 23 survivors, the ghastliest forms ever seen on earth. One of them, Mr Holwell, published a narrative in 1758; see also Macaulay's essay on Clive.

Blackie, JOHN STUART, a versatile writer, born in Glasgow in 1809, was educated at Aberdeen and Edinburgh, and in 1829 went to the Continent, where he continued his studies at Göttingen and Berlin, and afterwards at Rome. In 1834 he published a good metrical translation of Goethe's *Faust*, and in the same year passed as advocate at the Edinburgh bar. But the practice of his profession failed to wean him from literary pursuits, and he soon began to make himself known by his articles on German subjects contributed to the magazines of the time. In 1841 he was appointed to the chair of Humanity in Marischal College, Aberdeen, which he held until 1852, when he was elected to the Greek chair in the university of Edinburgh. After he became professor he took an active part in promoting educational reform, and in the movement that led in 1859 to the remodelling of the Scottish universities. His incessant activity in lecturing and writing letters to the newspapers showed his marvellous vitality and the breadth of his sympathies. He always figured as the patriotic champion of Scottish nationality and its characteristic features, and advocated with equal ardour the preservation of things as dissimilar as old south-country customs and the Gaelic language. During the years 1874-76 he advocated throughout the country with great enthusiasm the found-

ation of a Celtic chair in Edinburgh University, and was successful in raising upwards of £12,000 for its endowment. He resigned his chair in 1882 to become a kind of peripatetic philosopher, expounding throughout Scotland alternately wit and wisdom, and the inalienable rights of the Highland crofter. He published a fine verse translation of Æschylus in 1850, another of the *Iliad* in ballad metre in 1866, as well as several volumes of verse. His prose works embrace moral and religious philosophy, the method of history, the land laws, and a short life of Burns (1888). His principal philological papers were collected in *Howe Hellenica* (1874). He died 2d March 1895. See the Life by Miss Stoddart (1895), and the shorter sketch by his nephew (1896).

Blacking is the material employed for producing a black glazed shining surface on leather. The main ingredient in the various kinds of blacking is Bone-black (q.v.), which is mixed with an oil, some sugar, and a little sulphuric acid. The materials in Day & Martin's blacking are finely powdered bone-black ground with sperm-oil, raw sugar or molasses, a little vinegar, and some concentrated sulphuric acid (specific gravity 1.843). The substances are incorporated together one by one in the order in which they are stated, and the action of the sulphuric acid is to convert much of the lime in the bone-black into sulphate of lime, which causes a thickening of the mixture, and a tenacious paste results. This paste, diluted with weak vinegar, is put, whilst warm, in stoneware bottles, and is then ready for the market. For harness the blacking consists mainly of beeswax, softened with turpentine, and mixed with ivory-black, Prussian blue, and copal varnish.

Black Isle is the common name for the peninsula in Easter Ross, lying between the Beaully and Moray Firths and Cromarty Firth. See ROSS-SHIRE.

Black Lead (or BLACKLEAD), GRAPHITE, or PLUMBAGO, a mineral consisting chiefly of carbon, but containing also more or less of alumina, silica, lime, iron, &c., to the extent of 1 to 47 per cent., apparently mixed rather than chemically combined. Black lead is the popular name, and that by which it is generally known in the arts, though no lead enters into the composition of the mineral; graphite is that generally preferred by mineralogists. It sometimes occurs crystallised in flat hexagonal tables; but generally massive, and more or less radiated, foliated, scaly, or compact. It is of a grayish-black colour, with a somewhat metallic lustre, and a black and shining streak, and is perfectly opaque. It is greasy to the touch, and is a perfect conductor of electricity. It occurs in beds and masses, laminæ or scales in the schistose rocks (gneiss, mica-schist, clay-slate, &c.), and is sometimes in such abundance as to give its name to the schist (graphite-schist) in which it appears. It occurs also now and again in fissures in granite, or in scattered scales in various other igneous rocks, as in syenite in Norway, in porphyry in the Harz, &c. Thick vein-like masses of black lead are met with in Siberia, Spain, Canada, New Brunswick, United States (mines at Ticonderoga, N.Y., supplying almost the whole output), Ceylon, and elsewhere; the once extensive supplies of Borrowdale in Cumberland are now exhausted. It is far more incombustible than even anthracite (or *blind-coal*), burning with much difficulty even before the blowpipe, on which account it is much used for the manufacture of crucibles or 'melting-pots,' which withstand a great heat. These are not, however, made of mere black lead, but of black lead in powder, mixed with half its weight

of clay. Black lead is employed for making Pencils (q.v.). It is also extensively employed to give a black gloss to iron grates, railings, &c., and to diminish the friction of belts, machinery, and rifle cartridges.

Black Leg. See BLACK QUARTER.

Black Letter (**Black Letter**), the name which came into use about 1600, and is now commonly applied in this country to the types that on the Continent are most generally known as Gothic. The first printed books imitated every peculiarity of the contemporary manuscripts; and as printing was first practised in Germany and the Netherlands, the first types were copies of the letters in use in those countries in the middle of the 15th century. Two sorts of letters have been employed in the writings of Western Christendom. What have been called *Roman* letters prevailed from the 5th to about the close of the 12th century, when they gradually began to pass into what have been called *Gothic* letters, which continued till the 16th century, when, in most European countries, they were superseded by Roman letters. The first types, as has been said, were Gothic, and they spread with the art of printing into various European states. In France and Italy they were slightly modified by cutting off some of their rougher points; and when thus trimmed, they came to be known in the former country as *lettres de sonne*, being so called, it is said, from their use in an edition of the *Summa* of St Thomas Aquinas. The classic taste of Italy could not long tolerate the Gothic character even of the *lettres de sonne*; and they were still further modified, until they assumed the shape to which the name of Roman letters has since been given. The first works printed with these new types were two beautiful editions of Pliny's *Natural History*: the one by John of Spire at Venice in 1469; and the other by his disciple, Nicholas Jenson, also at Venice, in 1472. Another Venetian printer—the first Aldus Manutius—attempted in 1501 to supersede the Roman letters by what have been called *Aldine* (q.v.), or Venetian, but are best known as *Italic* characters. These can scarcely be said to have come into much more than temporary or exceptional use; but the Roman letters in no long time spread from Venice all over the west of Europe. Although thus supplanted in general use, the Gothic or black letter was long retained for special purposes, such as, in this country, the printing of Bibles, prayer-books, proclamations, and acts of parliament. Books in black letter being the earliest, are highly prized by antiquaries and bibliomaniacs, who are hence sometimes spoken of as ‘black-letter devotees.’ A form of the black letter still continues in general use in Germany; but about half of the books printed there are now in Roman letters. See PRINTING. The *Black-letter Saints' Days* of the Anglican calendar were so called from being printed in old calendars in black or ordinary letters, whereas the greater feasts were usually printed in red (hence Red-letter Days).

Black List. Such is the name familiarly applied to printed lists connected with insolvency, bankruptcy, and other matters affecting the credit of firms and individuals, which are circulated for the private guidance of the mercantile community. These lists are for the most part published in London weekly; but some are bi-weekly. In their contents are embraced the English bankruptcies and liquidations by arrangement under the Act of 1832; the bankruptcies of Scotland and Ireland; Scottish registers of protested bills; decrees in absence; judgments for debt in the Irish courts; offers of composition; dissolutions of partnership; warrants of attorney and cognovits; judges' orders;

bills of sale, &c. The legality of issuing information of this kind has been challenged, even when not freely sold, but limited to regular subscribers, on the ground that it amounts to a slander of the credit of the merchant whose name is given. In the case of the *Scottish Mercantile Society's Record* in 1848, it was found by the House of Lords that ‘such publication’ was not slanderous. In point of fact, the lists are only extracts from public registers, as are the ordinary lists of bankruptcies in the newspapers. The idea of furnishing to subscribers private lists of a more searching kind is due to Mr Thomas Perry of Cornhill, the proprietor of the ‘Original Bankrupt and Insolvent Registry Office, for Protection against Fraud, Swindlers,’ &c.; and similar lists are prepared by the Scottish Trade Protection Society, Edinburgh. Stubbs' is the best known publication of this kind. In the United States, the vast system of the mercantile agency and other similar institutions provides information of this kind; and printed lists of forgeries of bank-notes are issued. In one of these *Counterfeit Detectors* may be counted some thousands of varieties of forged bank-notes in circulation.

Blacklock, THOMAS, D.D., the blind poet, was born of humble parentage at Annan in 1721, and lost his sight through smallpox before he was six months old. After going through the necessary course of academic study in Edinburgh, he was licensed as a preacher of the Established Church in 1759, and in 1762 was ordained minister of Kirkcubright. The congregation objected strongly to the appointment, and in 1764 he resigned the charge in consideration of a small annuity. After this, he took pupils to board with him in Edinburgh till his death on 7th July 1791. It was a letter of his that arrested Burns on the eve of his departure for the West Indies, and thus, to all human appearance, saved from oblivion the greatest lyrist that the world has seen. The first volume of his own poor poems appeared in 1746; and a collected edition was published in 1793.

Blackmail, a rent or tribute formerly exacted by freebooting chiefs from the people in the Border counties of England and Scotland, and along the Highland border. It was a kind of compromise with robbers, and bought immunity from the attacks not only of others, but also of those to whom it was paid. It is mentioned in Archbishop Hamilton's *Catechisme* (1552) and in Maitland's *Thievis of Liddesdale* (about 1561), and it continued to be exacted along the Highland border until about the middle of the 18th century. The celebrated Rob Roy was about 1730 a notable levier of blackmail in the southern Highlands and adjacent Lowlands. Later, Coll M'Donnell of Barrisdale was noted farther north. For ‘blackmailing’ by threatening letters, see THREATS.

Black Monday, Easter Monday, 14th April 1360, so called from the extraordinary darkness and the fatally bitter cold.

Black Monks. See BENEDICTINES.

Blackmore, SIR RICHARD, court physician to William III. and Queen Anne, is remembered as the most heavy and voluminous of poetasters. Born at Corsham in Wiltshire, he was educated at Westminster and Oxford, taking his B.A. in 1674. He was first a schoolmaster, then a London physician (1687–1722), and died at Boxted, Essex, in 1729. He seems to have been a good and well-meaning man, and the merciless ridicule of contemporary wits was due, in some part at least, to the moral and religious tone of his works, and to his free censures of the libertinism of the time. But the worthlessness of the poems has been amply confirmed by the judgment of posterity. *The Creation*, considered his best, Addison pronounces

'one of the most useful and noble productions in our English verse;' but few modern readers are likely to examine the grounds of this judgment, still less to agree with it. Blackmore wrote six epics in sixty books (choosing always the loftiest themes), besides versions of various books of the Bible, and theological, medical, and miscellaneous treatises.

Blackmore. RICHARD DODDRIDGE, a well-known novelist, was born at Longworth, Berkshire, in 1825, and educated at Blundell's School (Tiverton), and Exeter College, Oxford. He graduated in 1847, afterwards studied law, was called to the bar at the Middle Temple in 1852, and practised for a time as a conveyancer. Ere long he united the pursuit of literature with the management of a market-garden and orchard at Teddington-on-Thames, and there he died 20th Jan. 1900. His first publications were *Poems by Melanter* (1854), *Epullia* (1855), *The Eagle of the Black Sea* (1855), followed by *The Fate of Franklin* (1860), and a translation of the first and second books of Virgil's *Georgics* (1862). Other volumes of verse have followed these, as well as a complete translation of the *Georgics* in 1871. His first novels were *Clara Vaughan* (1864) and *Cradock Nowell* (1866), but his first distinct success was *Lorna Doone, a Romance of Eemoor* (1869), which reached a 38th edition in 1893. *Lorna Doone* is almost a great novel. The plot is good and well developed; the style has the quaint and pleasing flavour of its age, the time of James II., with Sedgemoor for its point of highest interest; and the figures have much more life and movement than in any other of his novels. His plots are usually defective in construction, and the human interest in his books is a much weaker element than that rare insight into and sympathy with inanimate life in which he stands alone among English novelists. He has described for us with absolute truth the Devonshire farmer as he lives and speaks; and many of his women, if somewhat shadowy in outline, are yet figures of rare tenderness and grace. His other novels are: *The Maid of Sker* (1872), perhaps his second-best story; *Alice Lorraine* (1875); *Cripps the Carrier* (1876); *Erera* (1877); *Mary Anerley* (1880); *Christowell, a Dartmoor Tale* (1882); *Tommy Upmore* (1884); *Springhaven* (1887); *Portycross* (1894); *Tales from the Telling House* (1896); and *Daniel* (1897).

Blackpool. a flourishing watering-place, since 1876 a municipal borough of Lancashire, on the coast of the Irish Sea, 18 miles WNW. of Preston. The population has risen from 1664 in 1851 to 3506 in 1861, 14,229 in 1881, and 23,846 in 1891; but the numbers who resort here during the bathing-season far exceed the permanently resident inhabitants, for Blackpool is one of the most frequented watering-places in the west of England, the sands being excellent, the views delightful, and the climate bracing. There are two fine piers, one of them with a splendid pavilion; a promenade 3 miles long, with electric trams; winter-gardens, an aquarium, a free library, and theatres. A tower of the Eiffel style, 500 feet high, with shops and entertainment rooms at the base, was erected in 1893-95.

Black Prince. the popular title conferred upon Edward (1330-76), eldest son of Edward III. (q.v.). It is said, but not proved, that the name was given from the colour of the armour worn by him.

Black Quarter. also called Black Spald, Black Leg, Quarter Evil, Blood Striking, Symptomatic Charbon, Chabert's Disease, is a contagious and infectious disease of cattle due to the presence of a specific organism, which usually exerts its malignant influence upon the tissues immediately

beneath the skin. It is caused by rich pasture on stiff, retentive, and undrained soil; or by sudden changes from poor to rich keep, particularly with animals in good health, thriving well, and putting on beef. It is a disease which affects animals of all ages, from six months to six years old, though by far the largest number of victims is in those ranging from nine months to two years old. The malady occurs chiefly in spring and autumn, though seen at all periods of the year.

The præmonitory signs are often overlooked. The animal may be observed with a sleek coat, voracious appetite, quick staring look, suddenly to stop feeding; the eyes become bloodshot; there is slight salivation or foaming at the mouth; and in the very great majority of cases there is lameness in one of the limbs, the cause of this lameness being the rapid formation of a tumour at the top of the limb. This tumour is at first hot and painful to the touch, but soon becomes dead in its centre, and the skin covering it becomes crackling, and crepitates. Occasionally the tumour may form in the head, neck, dewlap, the joints, or in the body itself, but usually in the withers and loins. The animal's temperature rises to 103°, or as high as 107° F. The pulse becomes rapid and weak; the pain is excessive. Animals in this state are costive at first, but occasionally violent diarrhoea supervenes, and the excrement is tinged by black extravasated blood, tumour rapidly increases in size, the lameness becomes more intense, fits supervene, and death usually occurs in from four to forty-eight hours, though some cases prove lingering. The disease is almost invariably fatal, and no treatment is of any avail.

Post-mortem Appearances.—Owing to decomposition taking place even before death, the first thing noticed is the great swelling of the body, due to the evolution of gases, not only under the skin, but also in the stomach and bowels. The blood is found to be red, and to coagulate readily, so showing that the disease is not a form of anthrax, as had always been supposed until quite recently. The lungs are congested, all the viscera are spotted with red patches, and are more or less congested. The specific lesions are found in the region of the tumour, which is indistinctly divided into three zones. Microscopic examination of a portion of the outer or middle zones reveals the presence of large numbers of micro-organisms, known as the Bacteria of Chauveau, which often contain one or more spores, and which, if introduced under the skin of healthy cattle, will produce black quarter.

Prevention is of two kinds. First, to render the pastures unfit to propagate the poison, by deep draining, whereby many pasture-lands, after having repeatedly ruined tenant-farmers, have been rendered perfectly safe from losses by black quarter; and, secondly, to render the system of the animal innocuous to the poison by protective inoculation. The method of inoculation which has met with the greatest success, both in England in a small way, and in France in tens of thousands of cases, is as follows: Take from an animal just dead of the disease a portion of the middle zone of the tumour, cut into small pieces, mix in a mortar with three times its weight of distilled water, then triturate; remove from mortar, and roughly strain through a piece of muslin; then carefully strain through three folds of fine muslin. Of the clear fluid so obtained take from 5 to 10 minims in a small syringe specially made for the purpose (Pravaz's), and inject it into the jugular vein of the healthy animal. The animal must be carefully secured before the operation. The needle of the syringe is then pressed through the skin into the vein, and then the piston of the syringe slowly pressed upon. During this part of the operation an assistant

should pour on the part some solution of boracic acid, so as to destroy any of the virus which might escape. The great difficulty of this operation is, that if the very slightest particle of the virus, instead of entering the circulation, should come in contact with any part of the wound, black quarter will be the result, and not protection. The second method is to take small pieces of the tumour and desiccate at a high temperature, and to introduce some of the dust so obtained under the skin of the healthy animal—a method which has not proved very certain or successful.

Black Rod. GENTLEMAN-USHER OF THE, an officer of the House of Lords, appointed by letters-patent. He is chief gentleman-usher to the sovereign, and usher of the order of the Garter, at the chapter-meetings of which he keeps the door. He has charge of all arrangements for maintaining order in the House; takes into custody any peer guilty of breach of privilege; and (himself, or by his deputy the yeoman-usher) summons the House of Commons to the Peers when the royal assent is given to bills, or when royal speeches are read. If the sovereign is personally present in the Lords, he *commands*, but if royalty is represented by Lords Commissioners, he only *desires* the attendance of the Commons. The appointment of messengers, door-keepers, &c., rests with Black Rod. His title is derived from his wand, surmounted by a gold lion, which he carries instead of the mace.

Black Rod of Scotland. See HOLYROOD.

Black Sea, or EUXINE (the *Pontus Euxinus* of the ancients), is an inland sea lying between Europe and Asia, extending from 41° to 46° 38' N. lat., and from 27° 30' to 41° 50' E. long. Its greatest length from east to west, on the 42d parallel, is 720 miles; its greatest breadth, near the west end, 380 miles; and its area, exclusive of the Sea of Azov, is 163,711 sq. m., according to Strelbitsky. On the south-western extremity it communicates by the Bosphorus, the Sea of Marmora, and the Dardanelles, with the Mediterranean, and on the north-east by the Straits of Kertch, or Yenikale, with the Sea of Azov. The Black Sea drains nearly one-fourth of the surface of Europe, and also about 114,000 sq. m. of Asia. Throughout its whole extent it has but one island, and that a small one, lying opposite the mouth of the Danube, called *Adassi*, or Isle of Serpents, on which is a lighthouse. In the centre its depth ranges between 1000 and 1070 fathoms, and as there are no shoals along the shores, except at the entrance of the Bosphorus, the navigation of the sea ought to be particularly easy and safe. It is so in summer; but in winter, being inclosed on every side, it becomes the scene of conflicting winds, and of storms which, though of short duration, are terrible while they last.

All the coasts are high, with good harbours, except between the mouths of the Danube and the Crimea; there the land is low, and the danger of navigation greatly increased in winter by the presence of floating ice; for, from the many large rivers which flow into this sea and that of Azov (Danube, Dniester, Bug, Dnieper, Don, Kuban, and Rion, in Europe; and the Kizil-Irmak and Sakaria, in Asia), the waters are fresher, and consequently more easily frozen than those of the Mediterranean. The specific gravity of the water of the Black Sea is 1014 (fresh water being = 1000), while that of the Mediterranean is 1028. The shores from Odessa to the Crimea are ice-bound during January and February; and although the harbour of Odessa is never frozen up, yet the drift-ice frequently renders the entrance to it dangerous.

There is no tide in this sea, but the large rivers

flowing into it give rise to currents, which are particularly strong in spring when the snows melt. There is a strong flow out through the Bosphorus.

The most important ports on the Black Sea are those of Kustendji, Sulina, Odessa, Nikolaiev, Kherson, Eupatoria, Kertch, Sebastopol, Poti, Batoum, Trebizond, Samsun, Sinope, and Varna.

The depth of the water is unfavourable to the extensive establishment of fisheries, but sturgeon are caught in the Straits of Yenikale, and other fish are abundant.

The ancients believed that the Euxine was at one time much more extensive, and that it had no connection with the Mediterranean, until the Thracian Bosphorus had been burst through by an earthquake, or by the great deluge known as the Deucalion deluge, which inundated Greece.

The sea has been navigated from a very early period. Its original Greek name was *Axeinos*, or 'inhospitable' sea, afterwards changed euphemistically to *Euxenos*, 'the hospitable.' In the time of Xerxes, large quantities of corn were exported from its ports to Athens and the Peloponnesus. The Romans and Byzantines, and also the Genoese, had large traffic on the sea. From the fall of Constantinople (1453), all but Turkish vessels were excluded from its waters, until the treaty of Kainardji (1774), when the Russians obtained the right to trade in it. Ten years after, Austrian ships were privileged to trade here; and by the Peace of Amiens in 1802 British and French ships were admitted. It was entered by the allied fleets, at the requisition of the Porte, in January 1854, and a dreadful storm in November of the same year caused great loss of life, shipping, and stores. By the Treaty of Paris (1856) it was opened to the commerce of all nations, and closed to ships of war, while the erection of arsenals was forbidden; but this article was repudiated by Russia in 1870, and in the following March, at a conference in London, the neutralisation of the sea was abrogated. Since then both Russia and Turkey have kept fleets in its waters. The Bosphorus and Dardanelles are still closed to other ships of war, but the sultan can open them at need to allies.

Black Snake (*Basanium constrictor*, see COLUBER), a species of snake common in the United States of America from Louisiana to Connecticut. Barring the white throat, it is of an almost uniform leaden colour, is one of the largest serpents in North America, and is remarkable for its great agility. It moves along the ground with a swiftness equal to that of a horse, glides over bushes, and climbs trees. It feeds on small quadrupeds, birds, frogs, &c.; frequently plunders poultry-yards of eggs; and enters dairies to drink milk or cream. A persistent enemy of the rattlesnake, it is generally the conqueror in a struggle, enveloping its venomous foe in its coils and crushing it to death. It has no poison-fangs, but is not slow to bite. It is easily tamed.—The commonest Australian snake (*Pseudochis porphyrieus*), found in marshy places, and somewhat cobra-like in its actions, is also called the Black Snake. The back is glancing black, the sides carmine, the belly red; the neck is not dilat-able. It may measure over 6 feet in length. It is very venomous, belongs to the family Elapidae, and is nearly allied to the Cobra (q.v.).

Blackstone, SIR WILLIAM, commentator on English law, was the posthumous son of a silkmere in London, and was born there 10th July 1723. In 1738 he obtained a scholarship from the Charterhouse to Pembroke College, Oxford; in 1741 entered the Inner Temple; in 1744 was elected a fellow of All Souls; and in 1746 was called to the bar, but failed to attract either notice or practice. In 1749 he succeeded an uncle

as recorder of Wallingford, in Berkshire; and in 1753 he delivered a course of lectures at Oxford on the law of England. Three years later, a Mr Viner having left £12,000 to endow a chair of English Law at Oxford, Blackstone was in 1758 appointed first Vinerian professor. Next year he returned to Westminster; and as the doctrines which he had taught as a lecturer had commended him to the Tory government of that day, he was made a king's counsel in 1761, in the same year becoming member for Hindon, in Wiltshire, and shortly after principal of New Inn Hall, Oxford. Other honours followed fast, and in 1763 he was made solicitor-general to the queen. In 1765-69 he published the four volumes of his lectures, which form his celebrated *Commentaries on the Laws of England*, and which brought him in £14,000. His practice, too, continuing to increase, he resigned in 1766 his Oxford appointments. Four years later he declined the solicitor-generalship, and, having been knighted, was made a justice of the Court of Common Pleas. He died 14th February 1780, and was buried at Wallingford.

Blackstone's fame rests wholly on his *Commentaries*. His seventeen other literary works, which included some youthful poetry, were inconsiderable, and his merits as pleader or judge were not of themselves such as to have made his reputation outlive him. As a commentator, he had many excellences. His style is in general clear and gracefully ornate, his illustrations are pleasing and felicitous. While he confined himself to exposition—to the accurate statement in scholarlike English of what had heretofore lain buried in the cumbrous language of lawyers like Littleton—Blackstone was unsurpassed, and rendered an important service to the country. But he was ambitious of combining with this exposition the higher task of explaining the reasons of law, as well as its merits and defects. For this survey of law from the legislator's point of view, he had not the requisite qualifications; his knowledge of English history was superficial, his study of the philosophy of law had been imperfect. With the works, indeed, of Montesquien and Beccaria he was acquainted; but the mode in which he quotes them shows that he had imbibed nothing of their spirit. The method followed in the *Commentaries* was as unscientific as could be imagined, and had not even the merit of originality. It was taken with little alteration and no improvement from Sir Matthew Hale's *Analysis of the English Law*. Possibly the haste with which the *Commentaries* must have been composed, being originally in the form of lectures, may have led to some of their imperfections. Since Blackstone's death the *Commentaries* have been very frequently reprinted, having reached a 23d edition in 1854, not to speak of various American editions and abridgments, such as Wait's (1875) and Ewell's (1883).

Blackthorn. See SLOE.

Blackwall, a suburb of London, in Middlesex, at the junction of the Lee with the Thames, 3½ miles ESE. of St Paul's. It has foundries, shipbuilding yards, East and West India Docks, and a tunnel under the Thames (opened in 1897).

Black Watch (Gaelic *Freiceadairn Dubh*), the first of the Highland regiments, had its origin in a commission granted to John, second Earl of Athole, in 1668, 'to raise and keep such a number of men as he shall think fitt' to be a constant guard for securing peace in the Highlands. The term *black* arose from the dark colour of their tartan uniform, which distinguished them from the regular troops, called the *Saighdean Dearg*, or 'red soldiers.' From 1704 till the Union,

there were three companies in existence directly dealt with by the Treasury in regard to pay and clothing, and wholly armed with firearms. In 1729 the companies were six in number—three comprising 100 men each, commanded by captains, and three of 70 men each, commanded by captain-lieutenants. The body was raised chiefly from the Whig or loyal clans—Campbells, Grants, Munros, &c. The duties of the Black Watch were to enforce the disarming act, to prevent political meetings of a seditious kind, and to check depredation. After being of considerable use for these local purposes, the whole of the companies were formed into the 42d Regiment, under the command of the Earl of Crawford, in 1739; and in 1743 the regiment joined the troops in Flanders, and first went into action at Fontenoy, since when it has been one of the most distinguished corps in the British army. As it was embodied under a Lowlander, it was necessary to adopt an arbitrary pattern of tartan, which has ever since been known as the 42d or Black Watch tartan. In 1872 the officers of the corps erected a monument in Dunkeld Cathedral in memory of those who had fallen in battle from the creation of the regiment till the close of the Indian Mutiny in 1859; and a memorial cairn, raised by public subscription, was unveiled, 13th November 1887, in the field near Aberfeldy, where the regiment first assembled in 1739. When in 1881 the numerical designations of the British foot regiments were dropped, the former 42d and 73d Regiments were made respectively first and second battalions of the 'Black Watch (Royal Highlanders).' For the costume of the Highland regiments, see HIGHLANDS; also Ross's *Old Scottish Regimental Colours* (1885).

Black Water, RED WATER, MUIR-ILL, or HEMO-ALBUMINURIA, is a dietetic disease of cattle, which is diagnosed by the following symptoms: Loss of condition, loss of appetite, obstinate constipation, dicrotonous and weak pulse, yellow mucous membranes, staring dry coat, and frequent passage of urine of a red-brown or almost black colour, and having a strong odour of rotten turnips. It is a rapidly fatal disease, and most frequently seen in ill-fed animals, or animals grazing on badly drained, poorly cultivated land. The cause of the disease is a want of proportion in the quantity and quality of the food, and particularly in a lack of albuminoids, and an increase in the watery constituents. The result of this bad food is to cause indigestion and constipation, which are then followed by a breaking down of the blood constituents, and elimination of the broken-down blood by the kidneys, the consequence being that the animal really succumbs from loss of blood or blood constituents. Examination of the urine reveals the presence of albumen, and also blood and bile pigments. Its specific gravity is increased to about 1040. On post-mortem examination, one finds great pallor and wasting of the tissues and organs, emptiness of the blood-vessels, dark-coloured urine in the bladder, engorgement of the liver, and distension of the gall-bladder with thick bile, and generally the appearance of bloodlessness.

The disease should be guarded against by draining the land, growing good grasses and turnips, and feeding the animals with food containing sufficient albuminoids. When animals become affected, administer a quart of oil, to remove any bad food from the stomach and bowels, and follow with twelve eggs and a quart of good ale night and morning, and warm clothing, linseed and cotton cake, port wine, drachm doses of sulphate of iron, or ounce doses of turpentine. A special form of this disease occurs in parturient cattle, which exhibits the same symptoms, but is induced in

weak animals by parturition, and manifests itself a week or so after parturition.

Blackwater, the name of numerous rivers and rivulets in Great Britain and Ireland, of which the longest are: (1) The Blackwater of Munster, 100 miles in length, which enters the sea at Youghal harbour; (2) the Blackwater of Ulster, 50 miles long, which falls into the south-west corner of Lough Neagh; and (3) the Blackwater of Essex, 40 miles long, which falls into the North Sea.

Blackwell, ALEXANDER, adventurer, seems to have been born in Aberdeen about the beginning of the 18th century, and to have been a younger son of the Rev. Thomas Blackwell (1660-1728), principal of Marischal College. He may, or may not, have studied medicine under Boerhaave at Leyden; anyhow, about 1730, he was a printer in London, and becoming bankrupt in 1734, was supported in prison by his wife, who published a *Herbal* (2 vols. folio, 1737-39) with 500 cuts of plants, drawn, engraved, and coloured by herself, her husband adding their Latin names, with a brief description of each. Next, in 1742, Blackwell turns up in Sweden, where, having cured the king of an illness, he was appointed one of the royal physicians, and undertook the management of a model farm. While still in the full enjoyment of court favour, he was charged with being concerned in a plot against the constitution, and after being put to the torture, was beheaded, August 9, 1747, protesting his innocence to the last.

Blackwell, ELIZABETH, the first woman that obtained a medical diploma in the United States, was born at Bristol in 1821. Her family emigrated to the States in 1832, and six years later the father died, leaving a widow and nine children. Elizabeth helped to support the family for some years by teaching, steadily devoting her leisure the while to the study of medical and anatomical books. After making many fruitless applications for admission to various medical schools, she was permitted to enter that of Geneva, in New York State, and to graduate in 1849. She next visited Europe to prosecute her medical studies, and after much difficulty was admitted into the extensive *Maternité* hospital at Paris, and St Bartholomew's Hospital in London. In 1851 she returned to New York, and there established herself in a successful practice. In 1869 she returned to England, where she took an active part in connection with questions of social reform and the position of women. She has lectured frequently, and is author of several popular books on the laws of health, especially for girls. See her autobiography (1895).

Blackwell, THOMAS, scholar, a brother most likely of Alexander Blackwell (q.v.), was born at Aberdeen in 1701, and took his M.A. in 1718. In 1723 he was appointed professor of Greek in Marischal College, and in 1748 its principal. He died at Edinburgh, 8th March 1756. He was author of *Inquiry into the Life and Writings of Homer* (1735), *Memoirs of the Court of Augustus* (3 vols. 1752-64), and two or three other works.

Blackwood, WILLIAM, a distinguished Edinburgh publisher, the originator of *Blackwood's Magazine*, was born in Edinburgh, November 20, 1776. After serving his apprenticeship to the book-selling business in his native city, and prosecuting his calling in Glasgow and London, he settled in Edinburgh as a bookseller—principally of old books—in 1804. In 1817, having six years before become a publisher on his own account, he issued the first number of *Blackwood's Magazine*. The literary ability displayed in this periodical was so much in advance of the monthly magazines then existing, that from the first it was a great success. Its

remarkable popularity was sustained by the papers of Wilson ('Christopher North'), Lockhart, Hogg, and other spirits, whom Blackwood had the liberality and tact to attract to his standard. Overwhelming its political and literary opponents, now with the most farcical humour, and now with the bitterest sarcasm—sometimes with reckless injustice—the magazine secured for itself a prodigious reputation, more particularly among the Tories, of whose political creed it has always been a resolute adherent. William Blackwood himself, who added literary tastes and acquirements to his profession of a bookseller, was the chief manager of his magazine, and conducted the whole of the correspondence connected with it until his death, which took place September 16, 1834. His place was filled, between 1834 and 1852, by his sons, Alexander and Robert, the early death of the former cutting short a career of great promise. Under John (1818-79), the third son, who was editor from 1852, *Magu* not only sustained but increased its reputation. The publishing business has been greatly extended since the days of the founder of the house, 'George Eliot's' novels having all but one issued hence.

See Mrs Oliphant's *Annals of a Publishing House* (1897) and Sir George Douglas, *The Blackwood Group* (1897).

Bladder (urinary) is a hollow bag for the reception of the urine. When moderately distended it has a capacity of about a pint, but under various conditions it is capable of holding far more. Thus, the bladder of a drunkard has been seen so dilated that it held twenty pints, and when completely paralysed there is no limit to its distension. Instances of very large bladders are not infrequent in females, but this is probably the result of over-distension, and not due to the female bladder being naturally larger than that of the male. Indeed, competent authorities state that the reverse is the case.

In all young animals possessing a bladder, it is elongated in form, indicating that originally it was a tube. In an infant it is pear-shaped—the condition which is permanent in quadrupeds; but as man gradually assumes the erect attitude, the lower part expands under the weight of the urine. In the adult, its size, shape, position, and relations to surrounding organs vary according to its state of collapse or distension. When empty it sinks deeply into the pelvis, and appears flattened above and below; when moderately full its form is rounded, but still it remains within the pelvis; when completely distended it projects above the brim of the pelvis, becoming an abdominal organ, and having an ovoid or egg-shaped outline. It now presents a *base* or larger end directed backwards, an *apex* or *summit*—the smaller end—directed upwards and resting against the lower part of the anterior abdominal wall. At the front of the base, the *urethra*, which leads off the urine, commences abruptly in a thickened portion named the *neck*. At this point the bladder is fixed to the walls of the pelvis by fibrous bands named *true ligaments*. In all other directions it is freely movable, although receiving support from surrounding parts such as rectum or vagina, according to the sex, also to a slight extent from blood-vessels and the two ducts from the kidneys (ureters), and lastly from the peritoneum, which, on account of its various reflections from the organ, forms folds known as the *false ligaments*. The wall of the bladder consists of several layers or coats, in which blood-vessels and nerves ramify. The *outer coat* is formed of peritoneum, which only partially invests the bladder, being found on its upper and posterior half. The *next coat* consists of bundles of muscular fibres arranged in various directions. Between this and the lining membrane there is a well-marked layer consisting of areolar tissue, in which the

blood-vessels ramify, and named the vascular or *submucous coat*. The lining membrane (*mucous coat*) is soft and smooth. It is continuous with the lining membrane of the ureters and that of the urethra. Being loosely attached, it is nearly everywhere thrown into wrinkles, which disappear as the bladder is distended. If an imaginary line be drawn between the openings of the ureters, and from each end of this line others be drawn to the orifice of the urethra at the neck of the bladder, a triangular portion of the base will be mapped out, having its apex pointing forwards, and each side measuring about an inch and a half. Within this area, to which the name *trigone* is applied, there are never any wrinkles, even when the bladder is empty, because the mucous coat adheres more closely to subjacent parts. This area has a greater number of blood-vessels and nerves than other parts of the bladder, and therefore possesses more acute sensibility. As the urine accumulates in the bladder, its pressure on the trigone gives rise to the feeling of a full bladder and the necessity for micturition. The intense pain produced by stone in the bladder is due to the same cause (see CALCULUS). As the bladder becomes distended, its muscular walls begin to contract periodically upon the fluid contents; so do the muscular fibres which surround the outlet of the bladder—viz. the urethra. As long as the pressure within the bladder is not very high, the latter is able to resist the former, as is seen during sleep; but after a certain stage of distension is reached, the contractions of the bladder wall overcome those of the fibres closing the urethra, and the bladder is emptied. This process occurs naturally in young children, but as age advances the fibres surrounding the outlet of the bladder come under the control of the will, and thus the urine can be voluntarily retained or expelled. The bladder is liable to catarrhal inflammation of the coats, to paralysis, and other affections. Rupture of the bladder by accident is usually fatal. For incontinence of urine and retention of urine, see URINE. There is no urinary bladder in birds (see BIRD).

In general *zoological* usage, the term bladder is applied (1) to that outgrowth from the dorsal surface of the gut which forms the Air- or Swim-bladder (q.v.) of many fishes, and serves in a few cases as an incipient lung; and (2) to the urinary bladder. It is necessary to note, however, that the latter may have a very different origin in different animals. (a) In the gristly fishes the terminal extremities of the so-called 'Wolffian ducts' coalesce to form a urinary cloaca, which opens into the general cloacal chamber. (b) In the bony fishes the urinary bladder is a dilatation at the exit of the ureter. (c) In amphibia the bladder arises as an outgrowth from the hind-gut, and represents the allantois of higher animals. (d) In reptiles the stalk of the allantois dilates to form a permanent urinary bladder, which is absent in birds. (e) In mammals the stalk of the allantois again dilates to form the bladder.

Bladder Campion. See SILENE.

Bladder-cherry (*Physalis alkekengi*). See WINTER-CHERRY.

Bladder Green is derived from the Buck-thorn (q.v.).

Bladder-nut (*Staphylea*), a very widely distributed genus of deciduous shrubs or small trees of rather elegant appearance, usually referred to the order Celastraceae (see SPINDLE-TREE). The Common Bladder-nut (*S. pinnata*) is frequently planted in shrubberies, as is also the North American *S. trifoliata*. The wood of both is firm and white, well suited for the purposes of the turner. The seeds yield a good oil, and may be eaten, but act as a mild aperient. The flower-buds are

pickled as capers. The name bladder-nut has reference to the curious inflated membranous

Common Bladder-nut (*Staphylea pinnata*):
a, a flower; b, fruit.

capsule, and the hard bony *testa* of the seed. The name *Staphylea* is from the Gr. *staphylē*, 'a bunch of grapes,' and has reference to the racemed flowers.

Bladder-seed (*Physospermum cornubiense*), an umbelliferous weed, noted for its inflated fruit.

Bladder-senna (*Colutea arborescens*), a leguminous tree of Southern Europe, occasionally planted in sheltered shrubberies. It owes its name partly to the dry inflated pod, partly to the tradition of the use of its leaflets for adulterating senna.

Bladder-worm, the asexual stage of a tape-worm or cestode. It is found encysted in a host which is likely to be eaten by the final host of the tapeworm. The stage owes its name to the bladder-like form resulting from the encysted embryo. Within the bladder a 'head' is developed (a in fig.), which is eventually turned outwards, and retains the bladder as a sort of appendage (b in fig.). In exceptional cases (see HYDATIDS) the bladder buds off internally, not one head but many. On passing to the final host the bladder-worm loses its bladder, and the head or scolex, becoming attached to the gut, buds off the familiar chain of 'joints,' which gradually become sexually mature. Before the life-history of cestoid parasites was understood, the bladder-worms were described as separate organisms, but they are now known to be simply the asexual stages of an 'alternation of generations.' Thus the *Cysticercus cellulose* or bladder-worm of the pig becomes the *Tenia solium* or tapeworm of man; the *C. mediocanellata* of ox, the *T. saginata* of man; the *C. fasciolaris* of the mouse, the *T. crassicolis* of the cat; the *Cenurus cerebralis* of the sheep, the *T. caninus* of dog; the *Echinococcus* of man, the *T. echinococcus* of dog, and so on. The bladder-worm is more passive, vegetative, and entirely asexual; the tapeworm

Bladder-worm.

joint is more active, its nutrition probably more stimulating and variable, its reproduction sexual. See CESTOD WORMS, TAPEWORM.

Bladderwort (*Utricularia*), a genus of Lentibulariaceae, which like its congener the Butterwort (q.v.) is remarkable for its carnivorous habit. The one hundred and twenty species are often aquatic or floating, the leaves frequently floating, and divided, the flowers generally yellow. The stems and leaves bear the characteristic insect-catching pitchers. See INSECTIVOROUS PLANTS.

Bladensburg, a village of Maryland, on the east branch of the Potomac, 6 miles NE. of Washington by rail. It was here that the battle which decided the fate of the capital was won by the British on the 24th August 1814.

Blackberry. See WHORTLEBERRY.

Blaes, a Scottish miners' name for the shale of the coal-measures, originating apparently from the 'blae' or bluish colour sometimes noticed in the shale. The term is occasionally used by geologists.

Blaeu (spelt also *Blaeuw* and *Blauw*, Lat. *Cesius*), WILLEM JANSZON, a map-drawer and printer, was born at Alkmaar, Holland, in 1571. His Terrestrial and Celestial Globes excelled in beauty and accuracy everything that had preceded them; as also did some of his maps. He died in 1638. —His son, JAN (died 1673), commenced business on his own account at Amsterdam in 1637, but afterwards entered into company with his brother, Cornelis (died 1650). His *Atlas Major*, in 11 volumes, is a remarkable work, with many curious plates; and the maps are extremely valuable from the light they throw on local history. Besides six maps of Ireland, the volume on Scotland contains forty-nine maps of that country, prepared by Timothy Pont (q.v.), and a great amount of local details by Sir John Scott. He further published a series of topographical plates and views of towns. Two of Jan's sons carried on the business until 1700.

Blagovestschensk, or BLAGOVYESCHENSK, capital of the Amur Province of Russian Asia, at the confluence of the Amur and Seja rivers, with some manufactures, an increasing trade, and 20,212 inhabitants. Khabarovka, lower down the Amur, at the confluence of the Ussuri, is the capital of the Maritime Province; and both Blagovestschensk and Khabarovka are on the line of the great Trans-Siberian Railway.

Blaine, JAMES GILLESPIE, journalist and statesman, born at West Brownsville, Pennsylvania, 31st January 1830, graduated at Washington College in 1847, and taught in a Kentucky military institute, and in the Pennsylvania institution for the blind. In 1854 he settled as a journalist at Augusta, Maine, and served in the state legislature from 1858 to 1862; from 1862 to 1876 he sat in congress, being Speaker in 1869-74. He was defeated in the Republican nominations for the presidency in 1876, 1880, 1884, and 1892. Senator for Maine in 1876, he acted as Secretary of State under Garfield, and again under Harrison (till 1892). He died January 27, 1893. He was the author of *Twenty years of Congress* (2 vols. 1884-86).

Blainville, HENRI MARIE DUCROTAY DE, zoologist and anatomist, was born in 1778, near Dieppe, studied medicine and the physical sciences at Paris, and in 1812 was appointed assistant-professor of Comparative Zoology, Anatomy, and Physiology, in the university, as well as professor of Natural History at the Athenaeum; in 1825 a member of the Institute; and in 1832 successor of Cuvier in the chair of Comparative Anatomy in the Museum of Natural History. He died May 1,

1850. Blainville achieved great success, not only as a teacher, but as the author of *Faune Française* (1821-30), *De l'Organisation des Animaux* (1822), *Cours de Physiologie Générale et Comparée* (1833), *Ostéographie* (1839-64), &c.

Blair, HUGH, was born at Edinburgh in 1718, and in 1730 entered the university, where his *Essay on the Beautiful* gave his preceptors a high idea of his ability and taste. In 1741 he was licensed as a preacher, and after occupying the churches of Collesic in Fife, Canongate, and Lady Yester's, he was promoted in 1758 to one of the charges of the High Church, Edinburgh. His discourses, which display little power or originality of thought, and which derived nothing from the delivery of their author, were greatly admired by 'persons of the most distinguished character and eminent rank' in Scotland on account of their polished style. In 1759 he commenced a series of lectures on *Composition* to classes in the university; and in 1762 he was appointed to a new regius chair of Rhetoric and Belles-lettres, with a salary of £70 a year. He resigned this post in 1783, and in the same year published his *Lectures*, which obtained a reputation far beyond their merits, and one that time has by no means confirmed. His *Sermons* (1777) enjoyed the approval not only of Dr Johnson, but of George III., who showed his appreciation by bestowing on Blair in 1780 a pension of £200 a year. Blair also published three other volumes of *Sermons*, and a fourth appeared after his death, which took place December 27, 1800. They were all as successful as the first. Opinion about their merits has much changed since the date of their publication; they are now considered as moral essays rather than sermons. Blair's critical acumen was not great; he strenuously defended the authenticity of Ossian's poems.

Blair, ROBERT, author of *The Grave*, was born in 1699 at Edinburgh, where his father was a clergyman. There and in Holland he was educated for the church, and in 1731 he was ordained minister of Athelstaneford, Haddingtonshire, where he lived in easy circumstances till his death 4th February 1746. He was an accomplished and thoughtful man, devoted considerable attention to natural science, particularly botany, and corresponded on friendly terms with several eminent contemporaries, among others, Watts and Doddridge. To them in 1742 he submitted the MS. of his poem, which Watts offered to two publishers. They thought it too heavy for the times, and it did not appear till 1743. It speedily attained an honourable place in the esteem of those capable of appreciating a masculine, though somewhat gloomy force of thought and imagery, applied to a profoundly suggestive and serious theme. In William Blake it found a congenial illustrator. Blair was succeeded in his ministerial charge by Home, the author of *Douglas*. His third son, Robert Blair, of Avontoun (1741-1811), became Lord President of the Court of Session.

Blair-Athole, a Perthshire village, situated at the confluence of the Garry and Tilt, 20 miles NNW. of Dunkeld. Blair Castle, the seat of the Duke of Athole, dates in its oldest part from the 13th century, and as restored in 1872 is a fine baronial structure. It has many memories of sieges and royal visits, from Queen Mary's days to Queen Victoria's. Claverhouse was buried in the old church of Blair.

Blairgowrie, a town of Perthshire, very picturesquely situated on the right bank of the Erich, 20 miles NNE. of Perth by a branch line (1855). It has flax spinning and weaving factories driven by the Erich. Pop. 3714.

Blair's College. See SCOTLAND, p. 247.

Blaize. See BLASIUS.

Blake, ROBERT, next to Nelson the greatest of English admirals, was born at Bridgewater, the eldest of the twelve sons of a merchant there, in August 1599. From the grammar-school of his native town he passed in 1615 to St Alban's Hall, and shortly afterwards to Wadham College, Oxford, where he remained till 1625. He seems next to have continued his father's business, and to have prospered, but may from time to time have himself made voyages to distant seas, as prosperous merchants at that time very often did. He led the life of a quiet country gentleman until he had reached his fortieth year, and was returned for Bridgewater to the Short Parliament of 1640, that prelude of the Civil War. He cast in his lot with the parliament without hesitation, but did not become a member of the Long Parliament till 1645. An ardent Republican, and a man of blunt, straightforward manners, singularly devoid of fear, and of inflexible character, he was much respected by Cromwell, but he never became personally very intimate with him. He served under Popham in Somersetshire, and attracted notice by his conduct at the siege of Bristol, and his obstinate defence of Lyme, in Dorsetshire, in 1644 against Prince Maurice. His defence of Taunton for nearly a year against overwhelming odds, when the town was little more than a heap of ruins, covered him with fresh glory, and proved a turning-point in the war.

In 1649 he was appointed with two others to command the fleet, at that time in a state of disaffection and weakness. Before two years he had blockaded Lisbon, destroyed the squadron of Prince Rupert, and forced the royalists to surrender the Scilly Isles and Jersey, their last stronghold. Early in 1652 began the struggle with the Dutch for the supremacy of the seas, and Blake found himself pitted against such redoubtable seamen as Van Tromp, De Ruyter, and De Witt. In the first engagement on the 19th May, though his fleet numbered over forty ships to Blake's fifteen, Van Tromp retreated under cover of darkness with the loss of two ships. It is right to add that the English ships were larger than the Dutch, and their artillery superior. On the 28th September Blake gave battle to De Ruyter and De Witt off the mouth of the Thames, both fleets about sixty-five ships in number. The fight ended with the flight of the Dutch next day. On the 29th November a fleet of eighty vessels under Van Tromp encountered Blake with scarcely forty off the Goodwin Sands. After a two days' hotly contested fight, victory remained with the Dutch. Blake lost six of his ships, but brought the remainder in a sadly shattered state into safety. In his report to the council of state he complains of the 'baseness of spirit, not among the merchantmen only, but many of the state's ships.' Van Tromp now scoured the Channel in triumph, and to this period belongs the apocryphal story of his having tied a broom to his mast-head. Blake asked to be released from his command, but by the middle of February 1653, he was again at sea with nearly eighty ships. On the morning of the 18th Van Tromp was sighted near Portland with about an equal force. A long running fight at once began, and lasted from Portland to Calais. Blake was severely wounded, but gained a complete victory, sinking five ships and capturing four, as well as over thirty merchantmen in Van Tromp's convoy. His ill-health prevented him from taking part in the engagement of the 31st July, which finally shattered the naval supremacy of Holland. In September 1654 he sailed with a fleet to the Mediterranean, where he soon made the English flag respected at Cadiz, Naples, and Leghorn alike. In April 1655 he sailed under the guns of Tunis, a nest of pirates, and burned a fleet of nine ships. He next sailed to Algiers, where the dey in terror

submitted to his terms. At the approach of winter he returned to England, but early in the spring of 1656 was cruising again off Cadiz. In September, Stayner, one of his lieutenants, fell in with the Plate fleet and captured it—a loss to Spain of nearly two millions in treasure alone.

But the crowning exploit of Blake's career was his last. Hearing early in April 1657 that a fleet from America had arrived at Santa Cruz de Tenerife, he at once sailed thither, and on the morning of the 20th arrived in the bay where there were sixteen ships lying at anchor, 'moored close along the shore, which lies in a semicircle, commanded as far as the ships lay by the castle, and surrounded besides with six or seven forts.' Before night he completely destroyed the fleet and the town, and contrived to draw off, owing to a favourable change of wind, with a loss of 50 slain and 120 wounded. The wonderful daring and success of this exploit excited the utmost enthusiasm throughout England, and admiration throughout Europe. But it was the last of the great admiral's glories. With health fast failing, he returned homewards to die just as his ship entered the harbour of Plymouth, 7th August 1657. Cromwell honoured his memory by a stately funeral, and caused him to be interred in Westminster Abbey, whence the body was ousted at the Restoration. A window to his memory was placed in St Margaret's, Westminster, in 1888. Blake's skill and courage were equalled only by his disinterested patriotism, sterling honesty, and love of justice; he not only gained a decided superiority over England's mightiest naval opponent, but, by the boldness and novelty of the tactics he introduced, taught English seamen to attempt every enterprise, however difficult and doubtful, with the same reckless and easy daring. See Hamay's *Admiral Blake* (1886) in 'English Worthies.'

Blake, WILLIAM, engraver, painter, and poet, was born in London on the 28th of November 1757, the son of a hosier. He was a dreamy boy, addicted to drawing and verse-making, and fond of solitary rambles in the country, during which he believed that he saw visions of angels in the sky and among the trees. At the age of ten he began to study art in Par's Academy in the Strand, and four years later he was apprenticed to James Basire, the engraver, in whose antiquarian prints he assisted, and for whom he executed drawings from the ancient monuments in the churches of London and its neighbourhood. His apprenticeship ended in 1778; and, after studying in the Antique School of the Royal Academy, he began to produce water-colour figure-subjects, and to engrave illustrations for the *Ladies' Magazine*, and, after Stothard, for the *Novelists' Magazine*. His first picture exhibited in the Royal Academy was 'The Death of Earl Godwin,' shown in 1780. His leisure had from early years been devoted to the composition of poems, of which the first volume, the *Poetical Sketches* by W. B., published in 1783, is full of true pastoral feeling and of an exquisitely spontaneous lyrical power. This work, with the *Songs of Innocence* (1789), and the *Songs of Experience* (1794), include the finest examples of Blake's poetry, for the so-called 'Prophetic Books'—the *Book of Thel* (1789), the *Marriage of Heaven and Hell* (1791), *The French Revolution* (1791), *The Song of Los* (1795), and many others—are strangely mystical and unintelligible, and owe most of the interest to the imaginative designs which are usually interwoven with their text.

All his poetical works, with the exception of the *Poetical Sketches* and *The French Revolution*, were produced in a method peculiar to the

artist himself, a method which, he related, was communicated to him in a vision by the spirit of a deceased brother. Their text, with its illustrative designs and decorative marginal enrichments, was inscribed upon copper-plates with a kind of stopping-out varnish, and the surrounding metal was then bitten away with acid, the result in each case being a plate in relief, which was printed on paper with ink of various tints, the impressions being finally coloured with extreme beauty and elaboration by the artist's own hand. His innumerable designs of poetic and imaginative figure-subjects were usually executed in washed monochrome or in water-colours. They include a superb series of 537 coloured illustrations to Young's *Night Thoughts*, of which 43 subjects were engraved by Blake and published in 1797, and 12 designs to Blair's *Grave*, which were etched by Schiavonetti and published in 1808. In his paintings Blake used a method which, he was accustomed to style 'fresco'—in reality a process of tempera upon a ground prepared with glue and whiting. Among the most important of such works is 'The Canterbury Pilgrims,' purchased by Sir William Stirling-Maxwell of Keir, Perthshire, which the artist himself engraved, a picture quaint in conception, and showing the errors and exaggerations of form common in the artist's productions, but full of character and individuality; 'The Spiritual Form of Pitt guiding Behemoth,' now in the National Gallery, London; 'Jacob's Dream,' shown in the Royal Academy of 1808; and 'The Last Judgment,' one of his latest paintings, executed for the Countess of Egremont. It is, however, in his engravings from his own designs that Blake's finest artistic work is to be found; and among these the 21 'Illustrations to the Book of Job,' hold the first place. They were the production of the artist's old age, published in 1826, when he was verging upon seventy. In imaginative force and visionary power they are unequalled in modern religious art and unsurpassed in the art of the past, while the directness and spirit of their method recalls the works of Durer and the other great painter-engravers of the 15th and 16th centuries. They were followed by the illustrations to Dante, upon which Blake was employed at the time of his death. He is also known as a wood-engraver by his series of 17 cuts contributed to a now very scarce edition of Thornton's *Virgil*. Though rude in execution, these prints are full of the very spirit of idyllic poetry, and their *technique* shows a remarkable perception of the true direction and special capabilities of the special artistic method.

During his life Blake met with little encouragement from the public. The exhibition of his works, which he held in 1809 in Broad Street, was a complete failure; his name was unknown to ordinary picture-buyers, and even at the end of his life, when he was producing his immortal 'Illustrations to the Book of Job,' he occupied, with his ever-faithful wife, a single small room in Fountain's Court, Strand. Yet he had his own little circle of true-hearted friends. The poet Hayley rendered him not ineffectual aid; Flaxman was his friend from youth; among his disciples in age were Samuel Palmer and John Linnell, and the generous assistance of the latter rendered his last days free from pecuniary anxiety. And all through his life he was upheld by the most real and vivid faith in the unseen, guided and encouraged—as he believed—by perpetual visitations from the spiritual world. He died in London on the 12th of August 1827, 'singing of the things he saw in heaven.' See Swinburne's essay (1868), and the editions of the life and works by Gielchrist (2d ed. 1880), and by Ellis and Yeats (3 vols. 1893).

Blanc, LE, a town in the French department of Indre, on the Creuse, 68 miles SSE. of Tours by rail. Pop. 4065.

Blanc, MONT. See MONT BLANC.

Blanc, JEAN JOSEPH LOUIS, a celebrated French Socialist and historian, was born 29th October 1811, at Madrid, where his father was inspector-general of finance under King Joseph. After finishing his school education he went to study in Paris. For two years he was a private tutor at Arras, and in 1834 returned to Paris, where he contributed to various political papers, and where in 1839 he founded the *Revue du Progrès*, in which he first brought out his chief work on Socialism, the *Organisation du Travail*, which in 1840 appeared in a separate form. The book obtained for its author a wide, enthusiastic popularity among the French workmen, who were captivated by the brilliancy of the writing, the simplicity of the scheme, and the freshness of the views advocated. The book denounces the principle of competitive industry, and proposes the establishment of social workshops (*ateliers sociaux*), composed of workmen of good character, and subsidised by the state. These workshops, conducted on the co-operative principle, and on the basis of an equitable remuneration for all engaged in them, would, he thought, in the process of time absorb all the industry of France. Next, in 1841–44, Blanc published an historical work, entitled *Histoire de Dix Ans* (1830–40), which produced a deadly effect on the Orleans dynasty. Louis-Philippe afterwards declared that 'it acted like a battering-ram against the bulwarks of loyalty in France.' It owed its success partly to the exposure it made of the scandalous jobbery and immorality of the crown and its advisers, partly to that passionate ardour which changed the tranquillity of history into the vehemence of a pamphlet. This was followed by the first volume of a *Histoire de la Révolution Française*, in which the author's aim was to describe from his own point of view not only the incidents of the first revolution, but the social history of the 18th century. On the breaking out of the revolution of February 1848, Blanc had an opportunity of playing a most important part. His great popularity with the working-classes led to his being appointed a member of the Provisional Government, and he was placed at the head of the great commission for discussing the problem of labour, which had its sittings in the palace of the Luxembourg. At the same time, Marie, Minister of Public Works, began to establish the so-called national workshops (see ATELIERS NATIONAUX), which, however, were in no sense an attempt to carry out the views of Blanc. Blanc was accused without reason of a share in the disturbances of the summer of 1848, and escaped to London, where he spent many years. During his exile, he devoted himself to political and historical literature. He finished his *Histoire de la Révolution Française*, and carried on a large correspondence for the French journals, a selection from which was published in the bright and charming *Lettres sur l'Angleterre*. On the fall of the Empire, Blanc returned to France, and was elected to the National Assembly in 1871. After 1876 he was member of the Chamber of Deputies. In both these bodies he voted and acted with the extreme Left, but without exercising any great influence on the course of events. He died at Cannes, 6th December 1882. Louis Blanc was a man of genial and amiable personality, and a sincere believer in the most advanced political and social opinions, which he advocated with polished and fervid eloquence, but he was not robust enough to be a revolutionary leader.

Blanch, or **BLENCH** HOLDING, is one of the ancient feudal tenures in the law of Scotland without service or prestation, except as a mere badge of superiority, the duty payable to the superior being in general a trifling sum, as a penny Scots, or merely illusory, as a peppercorn, 'if asked only,' or a bunch of roses, or, as in the famous case of Jock Howieson, a service of ewer and basin that the king may wash. Anciently, many estates in Scotland were held, both of the crown and other superiors, by this tenure, and by the legislation which followed on the Rebellion of 1745 all the ward-holdings or military tenures in Scotland were converted into blench; but it is now seldom adopted in the constitution of an original right of property. The tenure is subject to the same casualties of non-entry and relief as that of Feu (q.v.). See **CHARTER**, **TENURE**.

Blanchard, **EDWARD** **LAMAN**, journalist and theatrical writer, a son of William Blanchard, the comedian, was born in London, 11th December 1820, and early in life showed great aptitude for journalistic work and compilation for the publishers. Long a member of the *Daily Telegraph* staff, he wrote over a hundred pieces for the theatres, including many Christmas extravaganzas; he also published two novels. He died 4th September 1889. See *Life* by Clement Scott and Howard (1891).

Blanchard, **LAMAN**, born at Yarmouth, 15th May 1804, became a journalist in London in 1831, and died 15th February 1845. He was a popular writer of light literature. His prose essays were collected in 1846 as *Sketches of Life*, and his poetry in 1876.

Blanching, or **ETIOLATION**, is a process of culture resorted to by gardeners, to prevent certain secretions which, in ordinary circumstances, take place in the leaves of plants, and to render them more pleasant and wholesome for food. The action of light is indispensable to the decomposition of carbonic acid by the leaves of plants, and, consequently, to the elaboration of many of the substances from which they derive their peculiar qualities; the exclusion of light, therefore, renders them white or nearly so, and deprives them of much of their natural coarseness and bitterness. In cabbage and some other cultivated plants, the leaves of which form themselves into compact heads, there is a process of natural blanching. Artificial blanching is managed (1) by earthing up the leaves and succulent stems of plants, such as celery, asparagus, &c. For this purpose celery is planted in trenches, and earth is gradually drawn in round the stems as they advance in growth. (2) By tying together the leaves with strings of matting, as is sometimes done with lettuce, endive, &c. (3) By overlaying, which can be done with tiles, slates, pieces of board, or utensils made for the purpose. The most common is the blanching-pot, used to exclude the light from seakale, rhubarb, and some other culinary vegetables, in which the green colour is to be avoided. The common blanching-pot is of earthenware, in a sugar-loaf form, which is used in France for blanching lettuce, and in the Pyrenees for blanching celery, &c. Though so simple and easy, blanching is of great importance in gardening. Without it such a plant as seakale is uneatable if not poisonous; with it the common dandelion has become a wholesome and even medicinal article of salad.

Blanc-mange (Old Fr. *blanc-manger*, 'white food'), a dish formerly made of fowl, meat, eggs, &c.; now of gelatine or isinglass and milk, or of corn-flour and milk.

Blanco, **CAPE**, a remarkable headland on the west coast of Africa, in 20° 47' N. lat., and 16°

58' W. long., the extremity of a rocky ridge which projects from the Sahara in a westerly direction, and then bending southward, forms a commodious harbour called the Great Bay. Cape Blanco was first discovered by the Portuguese in 1441.—Cape Blanco (i.e. 'white cape') is also the name of several less important headlands in Spain, Greece, America, and the Philippines.

Bland Act. See **BIMETALLISM**.

Blandford, a town in Dorsetshire, on the right bank of the Stour, 10 miles NW. of Wimborne. It lies in a fine tract of pasture-land, famed for its multitude of cows. It suffered much in 1579, 1677, 1713, and 1731, from fire, only twenty-six houses escaping on the last occasion. It is built of brick, and is neat and regular; its chief charm is Bryanston Park, Lord Portman's seat. It was formerly famed for its manufactures of bandstrings and lace, the point-lace bringing £30 a yard. Shirt-buttons are made here. Pop. (1851) 3912; (1891) 3924.

Blandrata, **GIORGIO**, properly **BIANDRATA**, the founder of Unitarianism in Poland and Transylvania, was born of a noble family at Saluzzo, in Piedmont, about 1515. The freedom of his religious opinions compelled him to flee to Geneva in 1556, where he remained till Calvin's displeasure at his anti-trinitarianism drove him to Poland for liberty of thought and speech. Finally, in 1563, he betook himself to the court of John Sigismund, Prince of Transylvania, whose favourite physician he became. Here he exerted himself with as much prudence as assiduity to spread his doctrines, and succeeded in forming a considerable party. He died about 1590, strangled, so it was said, by his nephew, as he slept.

Blane, **SIR GILBERT**, physician, was born at Blanefield, Ayrshire, in 1749. He studied at Edinburgh University, and in 1779 sailed with Lord Rodney to the West Indies, where his gallantry under fire gained him the appointment of physician to the fleet. In 1783 he was elected physician to St Thomas's Hospital, London. As head of the Navy Medical Board, he was instrumental in introducing the use of lemon-juice and other measures for the prevention or remedy of diseases on board ship. In 1812 he had a baronetcy conferred upon him. He died June 26, 1834. He published several works.

Blank Bonds. See **BONDS**.

Blankenberghe, a village on the coast of West Flanders, 9 miles N. of Bruges by rail and canal, with a harbour and lighthouse. There are fisheries and shipbuilding, and the place is a popular summer-resort. Pop. 3328.

Blankenburg, a town and summer-resort of Brunswick, 37 miles SSE. of the capital, on the borders of the Harz Mountains. Pop. 7703, many of them miners.—There is a second Blankenburg, with 2330 inhabitants, in the Rodolstadt division of Schwarzburg-Rodolstadt, 25 miles S. by W. of Weimar. It is a favourite bathing-place.

Blanketeers, the name applied to a body of Manchester operatives who on 10th March 1817 met in St Peter's Field, provided each with a blanket for bivouacking. They meant to join a contingent from Derby, and march on London; but they were dispersed.

Blankets. The best qualities of those made in England are wholly of wool, but what may be called a typical English blanket of medium or inferior quality is generally formed of cotton warp and woollen weft threads, since, owing to the peculiar way much of the wool is spread in an open pile over the surface of the fabric, the cotton gives it strength. One of the chief aims of the

manufacturer is to raise the fibres of the woollen yarn into a loose, soft mat on the face of this kind of blanket, which hides the threads below. This is effected by Teazles (q.v.), or steel brushes, in what are called gigs or brushing machines. Scotch blankets, even of ordinary quality, on the other hand, are entirely made of wool, and are finished in a different way, the pile on the surface not being sufficient to hide the twilled pattern into which they are woven. An imitation of the Scotch blanket is made in some mills at Sowerby-Bridge in Yorkshire. Cloth or Bury blankets, again, have a surface more like ordinary woollen cloth. Witney, Kersey, Yorkshire, and Bath are the best-known varieties of English blankets. Dewsbury in Yorkshire is the principal centre of the trade. The Scotch blanket mills are chiefly situated in Ayrshire, Berwickshire, and at Markinch in Fife. Some blankets made in Ayrshire are not of the ordinary Scotch type. The 'Witney' and 'Bath' are perhaps the most comfortable blankets made in Great Britain, but none of the English kinds can compare with the Scotch blanket for economy. The latter is by far the most durable.

Foreign visitors to the Philadelphia Exhibition of 1876 were surprised at the luxurious nature of the more expensive kinds of American blankets exhibited, which find a market in that country at from thirty to fifty dollars a pair. An official report states that nothing comparable with these in weight, thickness, softness, and perfection of face had ever before been attempted. It also mentions that the lowest grades of blankets, composed of shoddy, hair, and the coarsest wool, which are saleable abroad, cannot be disposed of in America—even the savage Indians will not have them. Extraordinarily fine woollen blankets are made in Mysore in India; some, it is said, so delicate that, though as much as 18 feet long, they can be rolled inside a hollow bamboo. Such fancy blankets cost £30. English blankets range in price from four to forty shillings per pair. Some more costly kinds are made, but the market for them is very limited.

Blank Verse, or verse without rhyme, a name applied especially to the iambic pentameter or unrhymed five-foot iambic, the so-called heroic verse, the regular measure of English dramatic and epic poetry. The first specimen of blank verse in English is a translation of the second and fourth books of Virgil's *Æneid*, by the Earl of Surrey (beheaded in 1547); but it had been used freely by Italian and Spanish writers as early as about the beginning of that century. The first example of an English poem of any length (not dramatic) in blank verse is *The Steele Glas* (1576) of Gascoigne. Two short poems of Nicholas Grimald, published in *Tottel's Miscellany* in 1557, are the earliest specimens in English of original blank verse. In England the adaptation of this verse to the drama, from its elasticity and the freedom gained by the variations of the pause, was at once felt, and in that department of poetry it soon became and has continued dominant, if we except the effort made by Dryden and others, after the Restoration, to return to rhymed plays. For dramatic purposes the four-accent line is too short, and breaks the sense too often, while the six-accent line is so long as to be tedious without the relief of rhyme. The five-accent verse was a satisfactory mean between the two. The dramatic line, representing the language of actual life, approaches more nearly to prose, and consequently enjoys more license than any other metre. Not merely is the trochee freely substituted for the iambus after any pause however slight, but an extra syllable is also allowed at the end of a line or sentence (even in Milton), and in some cases even two extra

syllables, if these do not interfere with the regular recurrence of the accent.

Of course in verses of five accents it is impossible to divide the line into two *equal* parts, so that there must needs be variation in the position of the pause to avoid what would otherwise be unendurable monotony. In verse without rhyme much of the beauty of the rhythm depends on the poet's skillfulness in the variation of the pause, and no one has varied it with more boldness and finer effect than Milton. Professor Mayor points out that 'Tennyson and Browning, as compared with Milton, have more lines with final, but without internal pause; somewhat fewer with internal, but without final pause; about the same without any pause at all. As to the forbidden internal pauses, they use the pause after the first, third, and ninth syllables more frequently than Milton, and do not differ much from him in their use of the pause after one and a half, two, and eight. With regard to the middle pauses, those which divide the feet, coming after the fifth or seventh syllable, are more favoured by the moderns than by Milton, whose commonest pause is after the sixth syllable, and then *longo intervallo* after the fourth. The pause after the fourth seems to be Tennyson's favourite, while Browning seems to prefer the fifth and seventh. This last also abounds in Swinburne. Feminine ending is very rare in Browning, but in Tennyson is hardly less frequent than in Milton. Nor is there any marked difference as regards substitution of feet, except that the non-initial trochee is more common in Milton than in the others.' The initial trochee is as common in Surrey as in Milton. The rhythm of the former is frequently harsh and abrupt. Trisyllabic feet are not infrequent, and as often as not there is no middle pause. Marlowe's rhythm is much more regular in accentuation than Surrey's, but occasionally we find monosyllabic feet and lines of nine syllables formed by initial truncation. Feminine rhythm is also more frequent than in Surrey's usage, and even the two superfluous syllables at the end of the line occur here also. Many of Shakespeare's defective lines are capable of explanation by a pause or a lengthened syllable. Examples of elision and slurring are frequent, and trisyllabic feet are not uncommon, but genuine Alexandrines are not numerous. The superfluous syllable at the end is rare in his earlier plays, but there is a steady increase in its use in the later plays. It is but rarely a monosyllable, still more rarely an emphatic monosyllable. Such amphibrachic or 'double endings' are especially common in Fletcher's verse.

Dryden followed Corneille in demanding rhyme for the dignity of tragedy. He sums up its advantages in aid to the memory, in additional grace added by the sweetness of rhyme to the smartness of a repartee, and in the limits that it lays upon the fancy, which without such restraint tends to outrun judgment. Milton's *Paradise Lost* (1667) was the first great poem in our literature written in blank verse. Appended at the publisher's request was a short preface in three sentences, entitled 'The Verse.' Here the poet, with customary vigour of phrase, claims exemption from 'the troublesome and modern bondage of rhiming . . . to all judicious ears, trivial and of no true musical delight . . . no necessary adjunct or true ornament of poem or good verse, in longer works especially, but the invention of a barbarous age, to set off wretched matter and lame metre.' From Milton's time blank verse has been as common a form for narrative, didactic, or descriptive poetry, as rhymed couplets with their 'jingling sound of like endings.' Some would restrict the name blank verse to the ordinary heroic metre or lines of ten syllables; by others the

term is applied more widely to unrhymed lines, irrespective of their length, from such examples as the *Huacacha* of Longfellow, which contains eight syllables in its lines, to his *Ecangeline*, which has as many as sixteen or even more.

The five-foot iambic appears early in both Italian and French, but in neither did it shake off the bondage of rhyme, as it did in England by the middle of the 16th century, so as to offer a sufficiently strong and flexible form for dramatic and epic poetry. French influences long exercised a restraining effect on its use in German, but English freedom made its way through the efforts of the elder Schlegel, Wieland, Klopstock, Herder, and others, until Lessing employed the unrhymed five-foot iambic in his *Nathan* in 1778, and thus set a precedent for its use in dramatic poetry. In earlier German verse in this measure as in French, each five-foot line was complete in itself, but Lessing introduced the usage of the Italians, and still more the English, of connecting lines by *enjambement* and building them up into long periods. Schiller's first plays were written in prose, but in 1786 he began to employ the five-foot iambic as modified by Lessing.

See chapters ix.-xii. of J. B. Mayor's *Chapters on English Metre* (1886), with its 'Postscript' containing a summary of an essay by Zarncke (Leip. 1865).

Blanqui. JÉRÔME ADOLPHE, a French economist, was born in 1798 at Nice, and commenced the study of philology at Paris, where he became acquainted with J. B. Say, who induced him to turn his attention to political economy. In 1833, on the death of Say, he was appointed professor of Industrial Economy in the Conservatoire des Arts et Métiers, and became one of the editors of the *Dictionnaire de l'Industrie*. In 1838 he became a member of the Academy of Moral and Political Science. Subsequently he travelled in several countries to study their economic condition. He died at Paris 28th January 1854. As a political economist, Blanqui was a follower of Say, and in favour of free-trade, and he recognised the social difficulties of his time. In method, he is ingenious; in style, transparent and lively. His most important work is the *Histoire de l'Economie Politique en Europe* (1838).—His brother, LOUIS AUGUSTE BLANQUI, was born at Nice in 1805, and made himself conspicuous chiefly by his passionate advocacy of the most extreme political opinions, for which he suffered with the pride of a martyr. He was one of the foremost fighters in all the French revolutions of this century. In 1830 he was decorated for his valour at the barricades. In 1848 he figured as the chief organiser of the popular movement under the Provisional Government. He took the lead also in the revolutionary *attentat* of the 15th May, the aim of which was to overthrow the Constituent Assembly. At the head of an excited mob, he demanded of the French representatives the resuscitation of the Polish nationality, while one of his friends pronounced the dissolution of the assembly. For his share in these disturbances he was rewarded with ten years' imprisonment in Belleisle. In 1861 Blanqui was sentenced to other four years' imprisonment. After the downfall of the second empire in 1870, Blanqui resumed his revolutionary activity, and in 1871 took a prominent part in forming the Commune. Being too unwell to endure transportation in New Caledonia, he was condemned to imprisonment for life, from which he was released in 1879. He died January 1, 1881, having spent nearly half his life in prison.

Blantyre. or HIGH BLANTYRE, a village of Lanarkshire, situated near the right bank of the Rotten Calder, 8½ miles SE. of Glasgow by rail, in a coal and iron mining district. Population, 2255.

Low Blantyre, 1½ miles NE., has dyeworks, and a weaving factory where young David Livingstone, the future African traveller, and a native of the place, worked as a 'piecer': here also are his memorial church and statue. Population, 1505.—Also the name of a Scottish mission-station founded in 1876, to the south of Lake Nyassa, Central Africa. It is situated on the heights between the Upper Shire and Lake Shirwa, in a well-wooded district.

Blaps. a genus of Black Beetles (q.v.), with more than 100 species. They are dark and darkness-loving forms, wingless, leisurely in their movements, feeding on dead vegetable matter,

Blaps.

and with the power of ejecting for several inches an acrid fluid of pungent odour. *Blaps mortisaga* is a common British species, of about an inch long, and of a shining black colour. It is sometimes called Darkling Beetle, and Churchyard Beetle, and sometimes seems to share with the Cockroach (q.v.) the appellation of Black Beetle. It is a frequent companion of the cockroach in pantries and cellars, and used to be thought a messenger of death, but is rather frequent for such an ominous function.—*Blaps sulcata* is cooked with butter and eaten by Turkish women in Egypt, under the notion that it will make them fat, this being, in their estimation, one of the chief points of beauty.

Blarney (from the name of a castle near Cork, in the wall of which is a stone, difficult of access, that is said to endue any one who kisses it with heroic powers of cajolery), an Irish colloquial term, now general, applied to any smooth and excessively complimentary or cajoling talk.

Blasius. ST. Bishop of Sebaste, Cappadocia, suffered martyrdom in 316. At one period his cult must have been widely diffused, judging from the extent of territory over which his relics were scattered. The wool-combers claim him as their patron, the reason being that iron combs were used to tear his flesh. He is said, moreover, to have saved the only son of a rich widow from choking by a fish-bone; hence he is invoked in extracting a thorn or anything sticking in the throat. His day falls on 3d February.

Blasphemy. according to the canon law, was either heretical or simple. The former consisted in denying God or an article of faith, and this was regarded as injuring the reputation of the Deity, and shocking the mysteries of religion. Simple blasphemy, on the other hand, consisted in making untrue and unbecoming statements about God, the Virgin, or the saints. These offences were severely punished both at Rome and in the Cismontane churches, though not with the capital penalty which was usual against blasphemers under the Jewish law. In England the law is partly statutory. A statute of 1698, which was repealed in 1813 so far as it protected the doctrine of the Trinity, declares it to be an offence 'to assert that there are more gods than one, to deny the Christian religion to be true, or the Holy Scriptures of the Old and New Testaments to be of divine authority.' The punishment is incapacity to hold office, and on a second conviction imprisonment for three years. Under this statute such writers as Matthew Arnold, F. W. Newman, and J. S. Mill could undoubtedly

be convicted, however serious and high-minded are their books. But the prosecutions for blasphemy in England have been under the common law, and there is a difference of opinion among the highest authorities whether the simple reverent statement of certain opinions amounts to blasphemy, or whether a scoffing and contumelious spirit is not necessary to complete the offence. The older cases, such as that of Woolston who in 1728 attacked the Christian miracles, Williams who published Paine's *Age of Reason* in 1797, Carlisle in 1819, and Moxon who sold Shelley's *Queen Mab*, tend to show that, as Lord Kenyon said, 'the Christian religion is part of the law of the land,' and therefore that to question its truth, however seriously, is an offence. The theory of such convictions is much weakened by the legislation permitting jurors and witnesses to avoid the oath, for it was thought that the theological sanction of Christianity was necessary for the due administration of justice. But the more recent case of Cowan, who in 1867 proposed to lecture on 'the character and teachings of Christ; the former defective, the latter misleading,' confirms the view that blasphemy depends on the character of the matter published, not the manner in which it is stated. The opposite doctrine was laid down by Lord Coleridge in the case of Foote and Ramsay in 1833. These men were guilty of scurrilous, offensive, and even indecent caricatures of Christian doctrine, and this is the character of much of the free-thought literature of the day. The complete toleration of religious opinion which now exists renders it so improbable that any one will be prosecuted for a decent expression of disbelief in Christianity, that it is unnecessary to discuss this point further. All the definitions of blasphemy protect not merely the leading Christian dogmas and the evidences of Christianity, but also the formularies of the Church of England as by law established. It may be pointed out that, as in the case of Page Hopps, at Glasgow in 1874, Unitarian books are held not to be blasphemous at common law, and to be therefore entitled to copyright. This would seem to imply that the principle laid down in Foote's case is right. In Scotland there is also a statute law and a common law of blasphemy. The Acts of 1661 and 1695 are un repealed, and it is still an offence punishable by fine and imprisonment to deny the authority of the Scriptures or the providence of God in the government of the world. It was under the latter statute that the atrocious judicial murder of Aikenhead, with the approval of the ministers of Edinburgh, was perpetrated in 1696. As in the case of the Edinburgh booksellers Paterson of West Register Street, and Robinson of Greenside Street, in 1843, it is a crime at common law to publish an impious book devised to ridicule or bring into contempt the Scriptures or the Christian religion. The accused in these cases were sentenced to fifteen and twelve months' imprisonment. The courts of the United States also hold that one who maliciously uses language calculated to sap the foundations of society and public order may be punished; but evil motive is essential to the offence, and discussion of religious doctrine is not to be interfered with.

Blast-furnace. See the articles BLOWING-MACHINES and IRON.

Blasting is the method of loosening or shattering masses of solid fracturable matter by means of explosive compounds. It is an operation of fundamental importance in Engineering and Mining, for, without the agency of powerful explosives, many of the greatest undertakings of modern times would have been practically impossible. Previous to the invention of gunpowder the only means of

quarrying stone and of extracting minerals from the earth was by the hammer, chisel, and wedge, or by the expansive power of heat. For obtaining large regular blocks of stone the wedge is still used, and blasting has to do not so much with quarrying as with disintegrating rock in the sinking of shafts, the cutting of tunnels, the formation of roads and railways, the removal of obstructions to navigation, and generally the shattering of solid masses, irrespective of the shape of the debris produced.

The explosives commonly used in blasting consist of gunpowder and preparations of nitro-glycerine, nitro-cotton or gun-cotton, and of several nitrates and chlorates. Blasting-powder contains less nitre than ordinary gunpowder, and is made in pellets of varying size, according to the extent of the blast. Nitro-glycerine is now used in the free condition only under exceptional circumstances, owing to the great risk of accidental explosion. As Dynamite (q.v.) it is absorbed and retained by porous ingredients with comparative safety and little diminished blasting efficiency. Gun-cotton (q.v.) is employed in the form of Lithofracteur, and in combination with nitrate of barium, under the name of Tonite. Blasting-jelly or gelatine, which is now largely used in the form of dynamite, consists of a solution of gun-cotton in nitro-glycerine, making a thick jelly-like mass of great explosive power. Numerous other explosives have been proposed and introduced, but many of them, from their instability, or from the great risks of their manufacture and handling, are prohibited under the provisions of the Explosives Act (see EXPLOSIVES). Among the drawbacks connected with the use of these substances must be reckoned the poisonous gases evolved by their explosion, and the danger of gas and dust explosions in fiery mines from sparks spread by blast-shots. For use in coal-pits, blasting-cartridges of highly compressed air, and of quicklime, have been proposed without success; but much more hopeful results are obtained from the use of the new water-cartridge, in which gelatine dynamite is surrounded with water.

The use of modern explosives renders three kinds of blasting practicable—(1) the small-shot system, (2) the mine system, and (3) surface blasts. The small-shot system consists of boring holes, 1 inch to 1½ inch diameter, sometimes more, and from 18 inches to 6 or 7 feet into the solid rock. The boring is done either by hand or machine power (see

Section of Mont Cenis Tunnel.

BORING. The hole is cleaned out, and the charge, generally in the form of a cartridge of sufficient diameter for the bore, is placed in its extreme end, and the remainder of the hole is tamped or closed with sand or clay. With the cartridge is connected a length of Bickford's time-fuse, which burns at a rate sufficient to enable the workmen to reach a shelter-place before the explosion takes place. In tunnelling and shaft-sinking a series of shot-holes,

which embrace the superficial area to be excavated are driven and exploded in a connected manner, a core or central set being first fired off, after which a ring of shots around the core are simultaneously fired, and so on till the whole area is embraced. The accompanying sectional diagram of Mont Cenis Tunnel shows the position of the shot-holes in the face of the workings. For this simultaneous firing, lengths of fuse corresponding to the number of shots are connected in a metal case, called an igniter, whence they pass each to a separate shot-hole. But single or combined shots are fired with great advantage by electricity, for which purpose special cartridges, provided with two insulated wires instead of time-fuse, are used. These wires are connected up to any number of shot-holes, and the explosion is produced by a current of electricity passing from a special apparatus.

Large blasts or mines are resorted to when great masses of rock have to be removed at once, or when a great supply of irregularly broken stone is required. These blasts are of two kinds—shafts sunk from the top of the rock, and headings or galleries driven in from the face. In a shaft mine the charge of powder is placed in a chamber cut at one side of the shaft, so that the tamping may not be in the direct up line of fire. It is exploded by electricity, the wires from the battery being protected from injury from the rough tamping by being embedded in battens placed up one side of the shaft. Headings are driven, if possible, along a natural joint in the rock. The explosive may be divided and placed in two or more separate chambers, and it is better to distribute large charges than to fire them at one centre. The charges in these mines vary from 600 lb. to 13,000 lb. of powder, and even more, and they should dislodge from 3 to 6 tons of stone per lb. of powder exploded. The Round-down Cliff, on the South-Eastern Railway at Dover, was in 1843 overthrown by a blast of 18,500 lb. of powder in three separate charges. At Craze Quarry, Argyllshire, in September 1886, a blast of 14,000 lb. of powder dislodged 60,000 tons of granite. Immediately after the explosion a crowd of onlookers rushed into the quarry, and by the liberation of poisonous gases in the confined state, nearly sixty persons were overcome, of whom seven died without recovering consciousness.

The removal of Hell Gate or Flood Island, in

Section Diagram of Hell Gate Tunnels.

Long Island Sound, New York, was the occasion of the greatest blast the world has yet seen. The island was about 9 acres in extent, and for blowing up this huge mass, it was honeycombed under low-water mark with tunnels—24 galleries running in one direction, intersected by 46 at right angles. These galleries were pierced in every direction with drill-holes, of which there were bored 12,561, with a depth of 9 feet, and a diameter of 3 inches—in all, more than 20 miles of drill-holes. Into each of these was inserted first, a cartridge of rackarock—one of Sprengel's patent explosives, consisting of

79 parts chlorate of potash and 21 parts dinitrobenzole; and, second, a cartridge of dynamite, the two together filling the entire bore. In all, there were used 240,399 lb. of rackarock and 42,331 lb. of dynamite. Water was admitted to the mine, and it was exploded on the 10th October 1885. In the operations 80,166 cubic yards of rock were tunnelled out, and 270,717 cubic yards were blasted. The resistance offered to the explosives equalled 500,000 tons of rock and 200,000 tons of water.

Surface blasts are explosions produced by firing the explosive simply in contact with, or placed near the substance to be shattered. Such blasts have become possible only since the introduction of detonating explosives. Gunpowder fired in an unconfined space would spend its force through the air, and produce little local effect; but the explosion of nitroglycerine, gun-cotton, and other nitro compounds is so sudden that it acts with enormous violence in every direction, though within a limited area. Thus blasts of detonating compounds laid on the surface of any rock, &c., and fired by a detonator, operate downward and produce great shattering effects. Surface blasts have been largely used in removing reefs and other obstructions to navigation in the Long Island Channel, New York, which altogether has been the arena of the greatest of all blasting operations. Surface blasting is illustrated by the effects of the few successful explosions which have been perpetrated by dynamitards in London and elsewhere.

Blastoderm, an embryological term applied to the layer or layers of cells arising from the germinal disc, or the portion of a partially segmenting egg which undergoes division. In ova where there is a large quantity of nutritive material or yolk, as in fish or bird, the whole ovum cannot divide, and only a small (germinal) disc of 'formative protoplasm' does so. The cells resulting from the division of this area become afterwards disposed in the ordinary germinal layers, and are in their earlier stages, as they grow round the yolk, and become in their area of origin the seat of embryonic development, called the blastoderm. See EMBRYOLOGY.

Blastoids. See ECHINODERMS.

Blatta. See COCKROACH.

Blaye (ancient *Blavia*), a river-port of France, in the department of Gironde, 20 miles NNW. of Bordeaux. It is built on the right bank of the islet of Gironde, here $2\frac{1}{2}$ miles broad, at the base of a rocky eminence crowned with Vauban's strong citadel (1652). Roland the Brave is said to have been buried at Blaye by Charlemagne. Pop. 4157.

Blazon, or BLASON (Ger. *blasen*, 'to blow,' as with a horn), a heraldic term which originated in the custom of blowing a trumpet to announce the arrival of a knight, or his

entrance into the lists at a joust or tournament. The blast was answered by the heralds, who described aloud and explained the arms borne by the knight. Blazon and blazonry thus came to signify the art of describing a coat of arms in such manner that any one acquainted with the technical language of heraldry may be able to draw it accurately from the description. The rules of blazon are explained under HERALDRY.

Bleaching (A.S. *blæcan*, from *blac*, 'pale,' 'bleak') is the whitening of textile materials or fabrics by the removal of coloured substances natu-

rally present or adhering to them in the course of their manufacture. It is also used to signify the decolourising of beeswax, castor-oil, and similar fatty materials by exposure to sunlight, sometimes in presence of water. From time immemorial open-air bleaching, with sun exposure, has been applied to linen and cotton fabrics, and is still for the most part the method adopted for domestic purposes. The strong bleaching power of direct sunlight is strikingly seen in the case of a wax or paraffin candle coloured with some of the aniline or vegetable dyes, an hour or two sometimes sufficing to discharge the colour. In diffuse daylight they also bleach, but much more slowly. Many dyes on textile fabrics, as is well known, soon fade if much exposed to the sun's rays.

It was formerly the custom to send linen goods manufactured in Scotland to be bleached in Holland, and the name *Holland* is still retained for a kind of unbleached linen. Another variety, which, from its fineness, was generally spread on the better grass-fields or lawns, received the name of *lawn*, still in use for a fine white linen. In those days large areas of grass land, and several months' exposure to air, light, and moisture, were required to bleach linen white. The first bleachfield in Scotland was established by the Fletchers at Salton in East Lothian about 1730; others were started soon after at Ormiston and Perth. Near Perth, and in Fife, there is still a good deal of open-air bleaching combined with chemical treatment. Bleach-works were also early set agoing about Glasgow and Aberdeen.

Andrew Yarranton, writing in 1677, mentions that a bleachfield then existed in Southwark by the side of the Thames, but there does not appear to be much known about early bleachfields in England.

In the old Dutch process the linen was immersed for some days in an alkaline lye of crude potashes, which removed a large quantity of the natural colouring matter and stains. It was afterwards treated with sour milk before it was spread on the grass. The process, including the field bleaching, took from six to eight months. Dr Home of Edinburgh discovered about 1756 that dilute sulphuric acid did better for the 'souring' operation than sour-milk, an improvement which shortened the time occupied in bleaching by one-half.

The modern process of bleaching calico, linen, and other fabrics of vegetable fibre, may be said to date from 1785, when Berthollet read to the French Academy an account of his investigations on the power of Chlorine (q.v.) to destroy colouring matters. A knowledge of the use of chlorine as a bleaching agent appears to have been first brought to this country by the Duke of Gordon and Professor Copland of Aberdeen, who communicated it to a firm of bleachers in that town. James Watt, who knew Berthollet, made the process successful at a bleachfield near Glasgow, and along with Dr Henry of Manchester, explained it to the Lancashire manufacturers of cotton cloth, a branch of industry then rapidly rising in importance. Mr Charles Tennant of Glasgow took out, in 1798, a patent for making a solution of the chloride of lime, and afterwards in 1799 made this substance in the solid state by exposing dry slaked lime to chlorine gas, which it readily absorbs in large quantity. This was a discovery of great importance. Under the name of *Bleaching Powder* this solid chloride of lime continues to be the chief material used as a bleaching agent. This substance is commonly called chloride of lime, but as explained under BLEACHING POWDER its exact nature is still uncertain. The use of the lime in the compound is simply as a convenient means of transporting the chlorine, but no one has since been able to find a safer

or better way of applying the chlorine to the bleaching of vegetable fibre. The bleaching action of this gas is supposed to result from its strong affinity for hydrogen, which it removes from the colouring matter and hence destroys it. In some cases the chlorine is believed to combine with the hydrogen of the water, forming a part of the colouring matter, thus liberating nascent oxygen, which has an energetic destructive action on organic bodies.

Bleaching of Cotton.—Cotton fibre as gathered from the seed contains some natural impurities, consisting of a kind of vegetable wax, margaric acid, pectic acid, and some other substances. These do not amount to more than 5 per cent. of its weight, and could be easily removed. But calico from the loom contains troublesome artificial impurities, often amounting to one-fourth of its weight. These chiefly consist of weavers' size, which is made up of starch, tallow, soap, and other ingredients. Oil from the machinery is also present. Before bleaching it is customary to singe calico so as to remove all projecting filaments. This is done by passing the cloth over a red-hot half cylinder of copper, or over a row of gas-jets. Sometimes a flame of carbonic oxide from a coke furnace is used along with heated copper, and another plan has been quite recently proposed—viz. to singe the calico by means of a metal bar or rod kept at a red heat by electricity.

The actual stages in the bleaching of cotton cloth which is to be printed are these: (1) Washing after the singe; (2) Boiling with lime in bowking kier: washing again; (3) Souring with sulphuric or muriatic acid, called the lime sour or gray sour: washing again; (4) Boiling with soda ash and resin: washing again; (5) Chemicking—i.e. treating the calico with solution of chloride of lime; (6) Souring with sulphuric or muriatic acid, 'white sour;' final washing.

Washing-machines.—For the repeated washings, the old dash-wheel is still to some extent used, and is a very efficient machine, but the operation can be got through in much less time by some more recent machines. One of these consists of a pair of squeezing rollers with suitable framework placed over a cistern, through which there is a continuous flow of clean water. The pieces of calico, joined at the ends, pass in a rope-like form between these rollers, descend into the water, pass round a submerged roller, and return to the pressure rollers, from which they again descend to the cistern. In this way, guided by a rail with pegs, the calico travels round in a spiral direction, descending and ascending till the operation is finished.

Bowking Kiers.—Barlow's high-pressure bowking kiers, which are much used, are worked in pairs. Each is a cylinder of boiler-plate large enough to contain 3500 lb. of calico, or about 40,000 yards of medium thickness. They are shown in annexed figure, one in section and the other in elevation. The pieces of cloth, sewed together in one length, after being passed through milk of lime, are introduced into the kiers through the manholes at M, M. A perforated plate, P, at the bottom of each kier supports the calico, which is piled up in regular layers. Two pipes, A and B, connect the kiers K 1 and K 2, the pipe A joining the top of K 1 to the bottom of K 2, and the pipe B joining the top of K 2 to the bottom of K 1. Communication between the kiers can be opened or closed by valves at V V, and in the centre of each there is a vertical perforated pipe T, called a 'distributor.' When they are filled the calico is held in its place by a grid on the top, and then high-pressure steam is admitted through the valves. The steam issues through the perforations of the distributor, and impinging against the calico, forces downwards the

lime-water, which is let off by the stopcocks SS, on the bottom pipes.

When the lime-water is all run off, the exit pipes are closed, and thin milk of lime is admitted by the pipe L to one of the kiers. High-pressure steam is

Pair of Barlow's High-pressure Bowking Kiers.

again admitted, which forces the liquor through the cloth to the bottom of the first, and onwards through the connecting pipe to the distributor of the second kier, from which it gets into the folds of the calico. When all the lime liquor has been forced from one kier to the other, the steam is shut off the first kier, and admitted to the second, by which the process is reversed. For about eight hours this alternate forcing of the liquor from one kier to the other is continued, after which the pieces are washed.

A low-pressure bowking kier with differently arranged details is preferred by some bleachers to Barlow's method.

Remarks on the Process.—Boiling the cloth with caustic lime after the singeing, came into use as a distinct operation in bleaching about 1820. The length of time occupied and the proportion of lime employed have varied at different times. At an early period one part by weight of slaked lime to a hundred of the cloth, with boiling for an hour or two, was thought sufficient; but now five or six times that quantity of lime is used, and the boiling is made more effective by being done under pressure.

The action of the lime is to decompose the fatty bodies, naturally present or imparted to the cloth. With these it forms an insoluble lime-soap which adheres to the fabric. If potash or soda were used, the soap formed would be soluble in water; but in practice an unequal distribution of the resulting fatty soap occurs, which could not be removed from the cloth without prolonged treatment. Accordingly, although no good theoretical reason for first forming a lime-soap appears very plain, the practice is universal. The calico after being washed with water is 'sour'd'—i.e. treated with weak sulphuric or muriatic acid, which combines with the lime to form soluble compounds readily washed away with water. This leaves the solid fatty acid adhering to the cloth, but now in the free state, when it readily combines with soda to form a soap soluble in water.

For this purpose, in the fourth operation, the soda is generally used in the form of a rosin-soap made by boiling rosin in solution of soda ash. This soap readily takes up the fatty acids which have been liberated by the souring treatment. The quantity of rosin used is not nearly enough to saturate all the soda, so that there is ample left to combine with the fatty acid, giving, when boiled with the cloth, a solution of mixed fatty and rosin soaps. The boiling lasts from six to twelve hours. A thorough washing gets rid of the soapy solution, and the cloth is then ready for treatment with solution of chloride of lime.

This is the fifth operation, and is called 'chemicking.' The cloth is drawn through a weak solution of bleaching powder, made by stirring the powder through a large quantity of water and allowing it to settle till clear. The clear solution is then diluted with water till the specific gravity is about half a degree Twaddell, or 1.0025. The cloth is left in this solution till thoroughly impregnated, and in some cases for a longer period, when the excess of bleaching liquor is pressed out by rollers. The calico is then passed through a weak acid bath, similar to that used after the liming operation, to liberate the chlorine from its combination with the lime, so as to allow of its full bleaching action. It is now only necessary to wash the lime compound thoroughly out of the fibre, and then the bleaching process is finished.

The Mather-Thompson bleaching process is Thompson's process, in which, instead of stronger acids, carbonic acid is used to liberate the chlorine from bleaching powder solution of about one-half the usual strength, adapted to W. Mather's continuous bleaching apparatus, based on a series of patents taken out in 1884 and 1885. The object of the chemical part of this mode of bleaching is to minimise the tendering of the cotton fibre. For a detailed description of the process see the *Engineer* journal for March 19, 1886.

Bleaching of Linen.—Flax fibre from which linen cloth is made, contains a much larger amount of natural impurities than cotton. At least it contains a greater proportion of other bodies than the useful part of the fibre. Again, water-steeping or retting, which is the first stage in the preparation of flax, darkens its natural colour. The impurities may amount to nearly one-third of its weight, and are chiefly mucilaginous bodies and dark-coloured resins. It follows that the bleaching of linen is a much more tedious process than what is required for cotton, and the machinery used differs considerably. Still the principle of both processes is the same. Exposure on grass, called 'crofting,' being to some extent necessary for linen, the bleaching of it can only be satisfactorily conducted at some distance from large towns. The bleaching lime and acid solutions require to be more dilute for linen than for cotton, because flax fibre is more easily destroyed by chemical agents.

Bleaching of Jute.—This fibre differs in its nature from cotton and linen since it does not consist of ordinary cellulose, but a more complex form of this body, in its composition, and called bastose. Jute can be easily bleached by permanganate of potash, but this is too expensive to be used on the large scale. In the laboratory it can be bleached by suspending it over phosphorus in a damp atmosphere, the oxygen of which is thus converted into Ozone (q.v.). Chloride of lime cannot be employed as such for the bleaching of this fibre, which is more easily injured by chemical agents, and especially acids, than linen. Chloride of lime, mixed with an equivalent quantity of sulphate of magnesia, and both dissolved in water, is used as a 'chemick' bath for jute. Another bleaching

liquor for this textile material contains sodium hypochlorite, obtained by the decomposition of chloride of lime with soda.

Bleaching of Paper.—Rags, esparto grass, straw, wool, jute, and other materials, are used for making paper, and these are usually bleached in the state of half stuff—i.e. after they have been so far reduced in the beating engine. White papers are largely made of esparto mixed less or more with rags. The half stuff is bleached with chloride of lime, which is subsequently washed out. Afterwards the paper material is generally treated with an 'antichlore,' consisting either of hyposulphite of soda or of hyposulphite of lime, to remove the last of the chlorine, which, if left, would rot the paper. Straw is easily bleached, but this is not the case with wood. When straw is used for making bonnets, it is bleached with sulphurous acid.

Bleaching of Wool.—Animal fibres, such as wool, hair, and silk, cannot be bleached by treatment with a solution of bleaching powder, because this substance would destroy them. Wool has naturally a coating of a peculiar substance, secreted by the sebaceous glands on the skin of the sheep, which dissolves to a considerable extent in water. 'Suint,' or 'yolk,' as this substance is called, is a complex fatty material partially saponified. It has a strong disagreeable odour, and contains a not inconsiderable quantity, varying with the kind of wool, of potassium salts. When wool is soaked in warm water, the natural soap in the suint is nearly sufficient for the removal of the whole of the fatty matter.

The process by which the suint is removed from wool is called 'scouring.' In this operation much heat or friction must be avoided, else, owing to its peculiar structure, the wool would felt, and, in consequence, many of the fibres would be broken in the carding or combing processes. The scouring of wool is effected in a bath of alkaline carbonates and stale urine, which, however, is also alkaline in its action, from the presence of carbonate of ammonia. Nevertheless, if the use of urine be dispensed with, and artificial carbonate of ammonia entirely substituted for it, the wool is left in a less favourable condition for spinning. Soap is sometimes added to the scouring mixture. Alkaline liquors require to be applied to wool in a dilute state. The soapy matters with which the wool becomes charged in the alkaline bath must be thoroughly washed out with clean water. There are a number of different machines in use for washing. The best kinds are those which agitate the wool least, and which, in their action, most nearly resemble washing in a natural stream.

The actual bleaching or whitening of wool is effected by the fumes of sulphurous acid (sulphurous anhydride), produced by burning sulphur in a close chamber or stove. Another process is to use the sulphurous acid in aqueous solution. This is got by dissolving a bisulphite such as the lime or soda compound, and adding acid. When wool or undyed woollen cloth is soaked in a strong solution of this substance, and then passed through a bath of weak muriatic or sulphuric acid, the sulphurous acid is liberated, and exerts its full bleaching action on the fibre of the wool. If wool is to be dyed a dark colour, it is not bleached in this way, but only scoured.

Bleaching of Silk.—Raw silk yields scarcely more than one-half of its weight of fibrine or true silk fibre. The other half consists of a kind of waxy material which stiffens the fibre, and is composed of albuminous, gelatinous, fatty, and resinous bodies along with a little colouring matter. Silk is first put through what is called an ungumming process, which consists of steeping it in very dilute muriatic

acid, and afterwards washing away every trace of the acid. The silk is then boiled with a strong solution of olive-oil soap if it is to be made white, or oleic acid soap if it is to be dyed. This removes a large quantity of the extraneous matter. The boiling requires to be done with great care, so as not to injure the lustre and elasticity of the fibre. Sometimes it is boiled a second time in hemp bags in a weaker soapy solution than the first.

As in the case of wool the silk after the 'boiling' is exposed to the action of sulphurous acid.

A recent improvement in the bleaching of silk consists in treating it with peroxide of hydrogen. The following instructions regarding the process are given in a small work on dyeing by Mr W. Crookes, F.R.S. 'The articles to be bleached must be freed from all mechanically adhering dirt, grease, &c. This is effected according to the nature of the article, and of the impurities to be removed, by means of soap, ammonia, sulphide of carbon, ether, or alcohol. These cleansing agents must then be entirely removed, either by washing or by evaporation. A bleach-bath is then made up with the peroxide of hydrogen, either alone, or along with small traces of ammonia or of soda-lye. The silks are simply laid in this liquid, and left to steep as may be required. The process is accelerated by heat not exceeding 77° F. and by the light of the sun. The bleaching process may last from two to fourteen days. When it is completed, the silks are rinsed in condensed steam-water, and carefully dried.' This peroxide of hydrogen process is also applicable to the bleaching of hair, feathers, furs, and leathers intended for dyeing.

For reasons somewhat similar to the use of lime as a carrier of chlorine in bleaching powder, Messrs Jacobsen of Berlin in 1887 proposed the dry powder of peroxide of barium to supply a bleaching bath of peroxide of hydrogen. When the peroxide of barium is stirred in water, and acid added, peroxide of hydrogen is at once obtained; but when certain salts are added the decomposition proceeds slowly, and the rate of production can be so regulated as to produce in a limited time the effect desired. Silicate of soda is the salt generally preferred, since it is slightly alkaline, which favours the bleaching action. The proportions used are 1 part barium peroxide, and 1 part dry powdered silicate of soda stirred in 100 parts of water. For vegetable fibres a stronger solution may be used, but for animal tissues some caution is required to avoid production of too much free soda. Flax and jute can by this process be bleached in one or two days.

Bleaching of Wood.—Trials made in 1887 in the bleaching of wood for ornamental purposes by means of peroxide of hydrogen have proved very successful. The wood is cut up to the required thickness, which may be from one twenty-fifth to one-fifth of an inch, and immersed in a bath of this liquid kept alkaline by the occasional addition of ammonia. In a few days this thin boarding appears almost white and transparent. It dries without shrinking or losing strength. The grain and veining, it is said, lose nothing of their distinctness from being subjected to the process; the colouring only disappears.

For the bleaching action of charcoal, and especially animal charcoal, on organic colouring matters in solution—such as the watery extracts of barks for medical purposes, brown sugar, paraffin, and a few other bodies—see CHARCOAL.

Bleaching Powder, a compound formed by the action of chlorine on dry slaked lime (see BLEACHING), was first manufactured on a large scale in Glasgow by Messrs Tennant & Co. The

use of chlorine for bleaching was introduced into Glasgow in 1789 by Watt, the engineer. At first it was used in the form of solution; but soon the addition of an alkali to the liquid was found to be beneficial, and the 'Eau de Javelle,' as this compound was called, was generally used. The next improvement was the substitution of lime for the alkalies, when Mr Charles Tennant in 1798 patented his *bleaching liquor*. In 1799 his partner proposed the use of dry slaked lime, and from that time to this the bleaching powder has remained unaltered in its nature. The manufacture of bleaching powder is one of the leading chemical industries of Great Britain, and at the present time it is looked on as the prop which supports many other industries, more especially the Leblanc soda manufacture. At one time the large quantities of hydrochloric acid gas produced in the manufacture of washing soda were allowed to escape into the air, destroying all vegetation for miles around. Restrictive acts of parliament, limiting the amount of gas which might be allowed to escape, resulted in the production of liquid hydrochloric acid, which was allowed, in many cases, to run into the streams. The manufacture of chlorine afforded an outlet for this (see CHLORINE), and the introduction of bleaching powder following soon thereafter, the useless by-product became the nucleus of a new departure, equal in importance to the soda industry itself. On the introduction of the Brunner-Mond process for making soda, bleaching powder became the mainstay of old soda-works, only able to keep working by making the bleaching powder pay for the loss on the soda they manufacture. For the decomposition of salt into sodium and chlorine, see SODA; see also HYDROCHLORIC ACID. An electrolytic or electro-chemical method of producing caustic soda and chlorine—i.e. from the decomposition of salt in water by means of strong electric currents—was begun on a commercial scale in 1894. The average market price of 'bleach' has varied much: in 1805 it was £120 per ton; in 1815, £80; in 1825, £27; in 1850, £13; in 1868, £10; in 1883, £5; in 1892, £10; in 1894, £9. In the manufacture of bleaching powder, the chlorine is passed into large stone or leaden chambers, measuring about 60 feet by 30 feet, and 5 feet high. On the floor of the chambers a layer of dry slaked lime, about 6 inches deep, is placed, and this is allowed to remain in contact with the chlorine for some hours, during which time the temperature rises considerably. The greater part of the unabsorbed chlorine having been drawn into another chamber, the door is opened, and the lime stirred up with rakes to insure uniformity, the strongest bleaching powder being found on the surface. Care is taken to transfer it to casks without exposure to wet or sunshine, as either of these are sufficient to induce decomposition and render it worthless.

The chemical changes which take place in the manufacture of bleaching powder are still under discussion; but the resulting product consists of hypochlorite of calcium, CaCl_2O_2 , along with a variable proportion of chloride of calcium, CaCl_2 , and uncombined lime. Its value is judged (see CHLORIMETRY) by the amount of chlorine which it can give up for bleaching purposes, the present market strength varying from 33 to 39 per cent. of chlorine, or 'available chlorine,' as it is called. Bleaching powder is a grayish-white powder, with a powerful odour resembling chlorine. It rapidly absorbs moisture in a damp atmosphere, at the same time losing its bleaching properties. Rubbed with water in small quantity, it forms a thin cream; but on the addition of more water, thickens to a paste, which again becomes thin when more water is added. It is principally used in the

bleaching of paper and linen; but as a disinfectant it is extensively applied in the purification of sewage or other obnoxious matter, its virtues from this as from every other point of view depending on the freedom with which it liberates chlorine. In the manufacture of chloroform large quantities of bleaching powder are required, and no practical process for producing this substance has as yet been devised which can dispense with bleaching powder.

Bleak (*Alburnus lucidus*), a little fresh-water fish belonging to the great Carp family (Cyprinidae), in the Physostomi division of bony fishes, in which the air-bladder (if present) opens into the gullet. Roach, dace, and minnow are familiar allies. The body is elongated and compressed, and measures 6 or 7 inches; the mouth is directed upwards; the chin projects; the nature of fins and tail is shown in the figure. The upper surface is bluish green, the sides and under surface silvery, the fins white or transparent. The bleak is common in European

Bleak (*Alburnus lucidus*).

rivers north of the Alps, and especially frequents quiet flowing water. Its active motions on the top of the water are familiar to anglers on English rivers. These fish form a large part of the food of pike, trout, and such fishes. Cooked like sprats, they are a satisfactory dish. As in related forms, the scales are coated internally with a silvery substance, which has for many ages been used for producing artificial Pearls (q.v.) and the like.

Blebs (allied to *blow*, *bubble*), same as *Bulla* (q.v.).

Bleeding, or **HEMORRHAGE**, is one of the most serious accidents which can happen to an animal, and constitutes the most anxious complication in surgical operations. As there is but a limited quantity of blood in the body (corresponding to about one-tenth of its weight), and as the sudden escape of a large portion of it is sufficient to cause death, every one should be instructed as to the measures which experience has shown to be the most efficient for preventing a dangerous loss of blood.

Bleeding may be either from a wounded artery or vein, or from a raw surface; and it may be in the form of a general oozing from the surface of a sore or a mucous membrane. We shall consider these varieties separately.

Arterial bleeding is recognised by the florid redness of the blood, and by its issuing from the cut vessel *per saltum* or by jerks. There are exceptions to this, however. When an artery has been tied, and bleeding occurs from below the ligature, the flow of blood is continuous, and of a dark colour.

If a large artery be severed, the first gush of blood may prove fatal, but more usually the patient faints, which implies a great diminution in the force of the circulation; and nature takes advantage of this respite to place the cut artery in circumstances as favourable as possible to the preservation of life—viz. the artery draws up within its sheath (see ARTERY); the blood, no longer impelled so vigorously by the heart, clots between the cut end of the vessel and the cellular tissue surrounding it; the inner and middle coats not only retract but contract, and another clot forms

within the arterial tube. These clots—which, with the faintness and the contraction and retraction of the artery, are termed natural *hemostatics* ('blood-stoppers')—are sufficient in many cases to prevent a recurrence of the bleeding; but such a happy concurrence of circumstances is not to be depended on, and we must be prepared to adopt some of the many surgical or artificial means for restraining the flow of blood till Adhesion (q.v.) can occur between the cut surfaces of the coats of the artery. The principal surgical means are:

Immediate pressure, which may be applied by pressing the finger-tip on the place whence the blood is seen to flow. This may be kept up by pads of lint, or a coin of convenient size wrapped in cloth, and secured with a bandage to the part.

Pressure on the artery above, or as it comes to the cut part. This requires some knowledge of anatomy, but not more than any intelligent person may easily acquire. Thus, pressure on the inside of the upper arm, about midway between its front and back, will press the Brachial Artery (q.v.) against the bone, and arrest any bleeding from wounds of the forearm and hand. Pressure on the middle of the groin with a thumb placed crosswise will control the stream of blood in the femoral artery, so that none can escape from any wound of the lower limb below where the pressure is made. This pressure with the finger or thumb is very difficult to maintain with an adequate amount of firmness and continuity: hence it is well to substitute the handle of a door-key wrapped in cloth, for the direct pressure of the finger-tip, which rapidly becomes relaxed by fatigue.

Pressure on the course of the vessel may be very efficiently effected by tying a handkerchief (see *BANDAGE*) round the limb above where it is injured, and then inserting a stick, and twisting it sufficiently tightly. This is the principle of the original tourniquet, which was invented by Morel, a French surgeon, at the siege of Besançon in 1674. He got the idea from seeing how carriers tightened the ropes which secured bales of goods on their carts. It has been modified from time to time. At present it consists of a strap and buckle, a pad which may be adjusted over the course of the artery wounded, or likely to be cut in an operation, and a screw by which the strap may be tightened as the surgeon may deem necessary. See *TOURNIQUET*.

Pressure on the main vessel leading to a limb is only a temporary method of stopping bleeding, since it is not only very painful to the patient, but fraught with danger to the limb, which may mortify if it be too long continued. In a healthy man such pressure may be continued for five or six hours with impunity in case of urgent necessity, but a longer suppression of the circulation would almost certainly be followed by partial or complete death of the limb.

'*Actual*' *cautery*, or hot iron, is occasionally useful in bleeding from a bone, or at some points where pressure cannot be efficiently applied. It is the oldest method of stopping bleeding, and until the 18th century was much in use; but its abuse, and the natural horror felt for it by both patient and surgeon, have almost banished it from the list of surgical hemostatics. If used, the iron should be at a dull red heat, pressed for an instant in firm contact with the bleeding vessel. It causes shrivelling of the artery: and if the latter be small, it effectually stops the bleeding.

Ligature, or tying the artery, is a very old method of arresting hemorrhage, and certainly the best. It was not used generally, however, in operations until improved anatomical knowledge and more efficient tourniquets allowed surgeons the time necessary for its application.

Another method was introduced by the late Sir James Y. Simpson of Edinburgh, and was termed by him *Acupressure* (q.v.), or pressure from a long needle or pin inserted from without, so as to press the artery between it and the tissues. The pins are removed after twenty-four or forty-eight hours. This plan promised to supersede the older kinds of ligature, especially in amputations, where the vessels can be easily secured, and where occasionally they are found so brittle from disease (see *ATHEROMA*) as to break under the pressure of a thread, but, since the introduction of the absorbable ligature, it has been entirely discarded in surgical practice. This ligature, consisting of catgut, prepared tendon, or silkworm gut, has the peculiarity that when placed around an artery and imbedded in the surrounding textures, it gradually becomes absorbed by the tissues around it, and does not require removal from the wound as was the case with the older silk or thread ligature.

Venous bleeding is recognised by the dark colour of the blood, and its continuous flow. Pressure is generally found sufficient to arrest it, and it should be applied *directly* over the wounded part. In this case, pressure higher up the limb only does harm, by retarding the return flow of the Circulation (q.v.), and thereby increasing the bleeding from the injured vein. It is hence very important to distinguish venous bleeding from that which occurs from arteries. In both, direct pressure on the bleeding point is the first imperative indication for treatment; in venous bleeding this suffices for the permanent arrest of the bleeding in most cases; in arterial bleeding it must be supplemented by one of the methods already described.

When a very large vein is divided, its two ends must be ligatured; if it be only partially severed, the surgeon can sew up the wound in its walls in many cases, and its function as an organ of the circulation is thus preserved.

Oozing from cut surfaces partakes more of the characters of venous than of arterial bleeding, as there is no vessel sufficiently large to demand the application of a ligature. The actual cautery or cold may be used, or one of the many styptics—e.g. perchloride of iron—may be specially recommended; it may be applied on lint or a sponge; or local astringents, such as alum and tannin, may be employed; there are also the puff-ball, mushroom, agaric, and matico-leaves, cobwebs, felt, &c., which act mechanically, and owe their reputation chiefly to the pressure used in their application. The best remedy for this type of bleeding is the application of a steady stream of *very hot* water to the injured surface. If continuously applied at as high a temperature as the patient can possibly endure, rapid cessation of the oozing takes place. Some persons have a congenital tendency to bleed (the hemorrhagic diathesis); if such a one have a trifling cut, or have a tooth pulled, he bleeds perhaps to death. A prudent surgeon will not perform cutting operations on one of a hemorrhagic family.

Bleeding from the free surfaces of mucous membranes occurs when they are much congested. One may have fatal hemorrhage from the stomach, and yet no open vessel may be found after death, even on the most careful examination. In such a case, we must trust to cold and internal remedies, such as acetate of lead combined with opium, gallic and tannic acids, and the extract of Witch Hazel (*Hamamelis Virginica*).

In bleeding, of whatever kind, the posture of the patient is a matter of great importance. The recumbent position is associated with a diminished force of the circulation, and should therefore be adopted in all serious cases. If the bleeding occur in one of the limbs, the raising of the injured part

is in itself often sufficient to cut short the loss of blood, and this postural treatment should in all cases be employed in addition to the special local remedies above described.

Bleeding from internal organs, as the stomach or the lungs, is a very serious symptom, and must be immediately and carefully treated whenever it occurs. In any such case, the patient should be placed in the recumbent position in a cool airy room, the dress loosened to allow of cooling of the surfaces of the body, and the application of cold further effected by placing wet cloths over the chest and renewing them as soon as they become warm from contact with the body. All these remedies have the effect of slowing and reducing the strength of the circulation, and the patient therefore loses blood less rapidly. A table-spoonful of turpentine mixed with a little milk should be administered by the mouth at once, and another table-spoonful should be added to a jugful of boiling water, and the patient caused to inhale the vapour from it. This acts directly on the blood-vessels, tending to close them at the bleeding point. Keep the patient very quiet, and summon medical aid as speedily as possible.

BLOODLETTING (also called Bleeding or Depletion, and including Phlebotomy or Venesection, Arteriotomy, Wet-cupping, Leeching, and Scarification) is a method of relieving the human system in states of general or local plethora by the abstraction of blood. General plethora is best treated, according to this method, by withdrawing a considerable quantity of blood from the arteries (arteriotomy) or veins (venesection). Local engorgement, or *hyperæmia*, of a part is usually treated by abstracting blood from the smallest-sized vessels, or capillaries, present in the skin, by the methods of scarification or leeching. In these cases, the removal of blood from the superficial textures diverts the blood-stream in part from underlying tissues, and thus reduces the tendency to inflammatory action in the deeper structures. In general bloodletting the object is to reduce the strength of the blood-stream throughout the whole system, and thus to diminish the acuteness of feverish conditions. The most usually employed method of accomplishing this is by the opening of one of the superficial veins of the arm, and allowing a sufficient quantity of blood to escape from the blood-vessel thus operated upon. The vein chosen for the operation is generally one of those near the front of the elbow-joint, which can be conveniently reached in this region without disturbing the patient, and which can be closed after the operation by applying a dressing with the elbow bent when the operation is completed. In performing the operation, it is first essential to make the vein stand out clearly under the skin, and to do so it is necessary to remember that the veins return the blood from the extremities to the trunk, and therefore that pressure must be applied constricting the arm above the elbow, thus causing the veins to swell from retardation of the blood-flow within their walls. A bandage is thus tied tightly around the middle of the upper-arm, and, as a result of its action, the veins in front of the elbow-joint commence to swell and stand out as blue cords, distinctly to be seen through the delicate skin of this region. Selecting the largest of these swollen veins, the operator places his left thumb upon it immediately below the point where he desires to open it. This prevents any backward flow of the blood in the vein, and renders it yet more distinct at the point where it is to be opened. Now taking a sharp lancet in his right hand, the surgeon pushes its point steadily downwards through the skin into the blue column that marks the position of the vein, taking care, however, only to divide its outer wall and not to

transtix it completely. Having by this means made a slit about half an inch long in its outer wall, he withdraws the instrument and removes his left thumb from the vein. A steady flow of dark blood now takes place from the wound; this is received into a graduated glass vessel, by which the operator may gauge accurately the amount of blood removed. Should the flow of blood tend to diminish, the patient is requested to grasp some hard object tightly with the hand of the side operated upon, and an immediate increase will occur in the blood flowing from the wound. When a sufficiency of blood has been abstracted by this means, the operator places a large and firm pad of lint over the wounded vein, and bending the arm at the elbow to a right angle, bandages it firmly in that position, observing specially that the pad of lint is tightly pressed against the wound in the skin. When the bandaging is complete, and only then, the constricting band around the upper-arm may be removed. There is danger in removing it earlier, since air may enter at the wound in the vein; and, being sucked upwards into the chest, may cause sudden cessation of the heart's action, and a considerable risk of immediate death. On account of this danger, it is not advisable for unskilled persons to attempt the operation. When the bandage and pad are firmly applied, and when the constricting band is removed, the patient's arm is placed in a sling and kept at rest for a week, when the wound in the skin and the vein is generally healed, and the patient may be permitted to use his arm again without incurring any risk. In children the veins in the arm are too small to be operated on satisfactorily, hence the external jugular vein of the neck must be selected in such cases; but the danger of the entrance of air is still greater in this region than in the arm; the operation should therefore be reserved for very urgent cases, and only performed with the utmost caution. The amount of blood actually abstracted in bloodletting must depend on the age of the patient and the nature of the case. The operation would be scarcely necessary if less than a quarter of a pint is to be removed, and it is now rare to remove more than one pint at one operation, however severe the case in which it is employed. For the methods and effects of local bloodletting, see CUPPING and LEECH. For the bleeding of animals, see PHLEBOTOMY.

Bleek, FRIEDRICH, a German biblical critic, born 4th July 1793 at Ahrensböck in Holstein, studied theology first at Kiel, and afterwards under De Wette, Neander, and Schleiermacher, at Berlin, where he was appointed in 1818 a university tutor, and in 1823 an extraordinary professor of Theology. In 1829 he was called to Bonn, and he remained there till his death, 27th February 1859. Bleek's chief work was his commentary on *Hebrews*, which theologians so different as De Wette and Delitzsch have ranked among the first exegetical works of this century. Schleiermacher declared that the '*Charisma* of Biblical Introduction' had been specially given to Bleek; and it is by his *Einführung in das Alte Testament* (1860; 4th ed. 1878) and his *Einführung in das Neue Testament* (1862; 3d ed. 1875), which have been translated into English by Venables and Urwick, that he is best known in this country. Solid unpretentious learning and clear sober judgment equally distinguish these and his other posthumous works, which include his *Synoptische Erklärung der drei ersten Evangelien* (2 vols. 1862), and lectures on *The Apocalypse* (1862), on *Colossians, Philemon, and Ephesians* (1865), and on *Hebrews* (1868).

Bleek, WILHELM, philologist, son of the preceding, born in Berlin, 8th March 1827, studied

there and at Bonn, and accompanied Baikie's Niger expedition in 1854, but was compelled by ill health to turn back at Fernando Po. He joined Bishop Colenso at Natal in 1855, and after eighteen months' study of the Kafirs, settled at Cape Town, where in 1861 he was appointed keeper of the Grey Library. Here he was engaged chiefly in philological investigations until his death, 17th August 1875. His writings on Bushman and Hottentot philology and folklore are important, and the *Handbook of African, Australian, and Polynesian Philology* (3 vols. 1858-63) shows remarkable erudition; but his most valuable work is the unfinished *Comparative Grammar of South African Languages* (parts i. and ii. 1862-69), in which the position of the great Bantu family is assigned.

Bleiberg, a village in the Austrian duchy of Carinthia, 8 miles W. of Villach, in the valley of the Drave, near the celebrated Bleiberg (Lead Mountain). Pop. 830.

Blekinge is a province in Sweden, also called after Carlskrona (q.v.).

Blende (Ger. *blenden*, 'to dazzle'), a name given to a number of minerals composed chiefly of sulphur and of certain metals, all or almost all of splendid lustre, at least in fractures and the faces of crystals. It is also very often popularly applied more exclusively to one of these minerals, to which alone, perhaps, it originally belonged, Zinc Blende, Garnet Blende, or Sphalerite; also called, according to its chemical composition, Sulphide of Zinc. Among English miners it is known as *Black Jack*. It is abundant both in crystalline and in sedimentary rocks in many parts of the world, and is often associated with Galena (q.v.), or Lead-glance. It contains about 66 parts of zinc and 33 of sulphur, and is used as an ore of Zinc (q.v.); but the reduction of it is attended with difficulty, which much diminishes its value. It is usually brown or black, sometimes red, yellow, or green. It occurs both massive and crystallised in rhomboidal dodecahedrons, octahedrons, and tetrahedrons. Macles, or twin crystals, are remarkably common. It is very brittle; before the blowpipe it decrepitates violently, but only fuses on thin edges.—Manganese Blende is a rare mineral composed of sulphur and manganese.—Antimony Blende, or Red Antimony, is also a rare mineral composed of sulphur and antimony.—Ruby Blende is a name sometimes limited to Pyrargyrite or Red Silver (see SILVER, ORES OF), sometimes extended as a sort of generic term to include a number of other minerals composed of sulphur and metals, among which are Cinnabar, Realgar, and Orpiment (q.v.).

Bléneau, a village in the French department of Yonne, 29 miles WSW. of Auxerre. Here Turenne gained a victory over the Prince de Condé in 1652.

Blenheim (Ger. *Blindheim*), a village of Bavaria, 23 miles NNW. of Augsburg, memorable in connection with Marlborough's great victory over the French and Bavarians, August 13, 1704. The battle, however, really took place at the neighbouring village of Höchstädt, and is known to the Germans by that name. France and Bavaria on the one hand stood opposed to England and Austria on the other. The French and Bavarian army consisted of 56,000 men, commanded by Tallard, Marsin, and the Elector of Bavaria. Opposed to it was an army of 52,000 men, under the command of Marlborough and Prince Eugene. The French and Bavarian generals had no idea that the allies would act on the offensive, and accordingly, when, about two o'clock in the morning, the line of the allies put itself in motion, they believed that it was about to retreat.

Even at seven o'clock, when the heads of the eight advancing columns became visible, Tallard regarded the whole proceeding as a stratagem to cover the retreat. When the mistake was discovered the army was hastily drawn up in battle-array, and fought with dauntless courage; but at five in the afternoon Marlborough broke through the line of battle, and won a victory most complete and decisive. The French and Bavarians lost between 30,000 and 40,000 in killed and wounded and prisoners, besides 120 pieces of cannon and 300 standards. The loss of the victors amounted to about 5000 killed and 8000 wounded.—Near to Blenheim, also, the French defeated the Austrians in 1800.

Blenheim, capital of Marlborough district, New Zealand, on the Wairau River, near the coast, 20 miles S. of Picton by rail. Pop. (1881) 2107; (1891) 3294.

Blenheim Dog, or MARLBOROUGH DOG, a small and very beautiful variety of spaniel, much resembling the King Charles breed in form and general appearance, but differing in the colour, which is white, with orange or flame-coloured markings. In weight it should not exceed 5 lb. The Blenheim spaniel is the *Pyrame* of Buffon. It derives its English name from Blenheim Park, in Oxfordshire, where the breed was a favourite one from the beginning of the 18th century.

Blenheim Park, near Woodstock, Oxfordshire, the seat of the Duke of Marlborough, erected at the public expense in the reign of Queen Anne as a testimony of gratitude to the victor of Blenheim. The sum, £500,000, that was voted for the purpose did not suffice for the completion of the work. The royal estate of Woodstock, in which it stands, was granted at the same time. The building was designed by Sir John Vanbrugh, and is a grand though heavy monument of his powers as an architect. The length of the principal front from wing to wing is 348 feet. The interior is proportionally magnificent, but its priceless collections of gems and paintings, and its library, were wholly or largely dispersed by auction between 1875 and 1886. Eleven of the pictures were offered to the nation for £350,000; amongst those acquired for the National Gallery was the *Ansidei Madonna* by Raphael, at a cost of £70,000. Among the objects of interest in the grounds are a triumphal arch, and a column 130 feet high, surmounted by a statue of Marlborough. An inscription on the pedestal, written by Bolingbroke, recites the public services of the hero. The park, 2700 acres in area and 12 miles in circuit, was laid out by 'Capability' Brown. Its trees are said to have been planted as the troops were ranged at Marlborough's victory; and a mighty bridge spans the rivulet Glyme, which then widens out into an artificial lake. See Marshall's *History of Woodstock* (Oxford, 1873).

Blennorrhœa (*blenna*, 'mucus,' *rheō*, 'I flow') is a medical term for an unusually copious discharge from any mucous membrane; but as it has been rather vaguely and inconsistently employed, most modern writers do not often make use of it. It has been used chiefly of discharges from the genito-urinary mucous membrane (see GONORRHOEA), from the conjunctiva, and the lachrymal sac (see EYE, DISEASES OF).

Blenny (*Blennius*), a genus of bony fishes, belonging to a large family (Blenniidae), in the division with spinous rays (Acanthopterygii). The family is characterised by Günther as follows: Body long, low, more or less cylindrical; naked, or with small scales; usually slimy. Dorsal fins extend along most of the back, often with prominent spinous rays. The hind fins are on the

throat, with few rays, and may be rudimentary or absent. The family includes 32 genera, with more than 200 species, widely distributed on the coasts of temperate and tropical seas, though some are found in brackish or even fresh water. The Sea-wolf or Cat-fish (*Anarrhichas*), with its formidable teeth; the slimy Butter-fish (*Centronotus*); the Viviparous Blenny (*Zoarces viviparus*), which brings forth its numerous young alive, and is popularly credited with being the parent of eels (Ger. *aal-mutter*); the brightly coloured Salaris; and many other interesting forms, belong to this family. They are carnivorous, and somewhat indiscriminate in their diet. There are but few British representatives.

The blennies themselves have moderately elongated, short-tailed, naked bodies. There is usually a tentacle over each eye. There are about 40 species, which are usually marine, though several live temporarily or constantly in more or less fresh water. They swim in small shoals, and can live on the wet shore for a much longer time than the absence of a tide. They are said to use their ventral fins in clambering among the seaweed. They are all greedy flesh-eaters. *B. gultorugine* is rare on British coasts, but abundant farther south. The Butterfly Blenny (*B. ocellaris*) is a quaintly

The Butterfly Blenny (*Blennius ocellaris*).

pretty little fish about 3 inches long, with flowing spines, and with an eye-like spot on its dorsal fin. It is most frequent towards the Mediterranean. The Smooth Blenny or Shanny (*B. pholis*), with similar distribution, has the spinous portion of the dorsal fin separate from the soft portion, and is of an olive-green colour irregularly marked with black spots. Like some of the others, it has in both jaws a long curved tooth, which it is said to use in detaching molluscs. There is no eye-tentacle. This organ is best developed in *B. tentaculatus*, a Mediterranean form. *B. vulgaris* is found in fresh water in Italy, and also in the Rhone. The blennies are but rarely used as food, but their activity and hardness make them favourite inmates of aquaria. See Günther's *Introduction to the Study of Fishes*.

Blessing. See BENEDICTION.

Blessington. MARGUERITE, COUNTESS OF, was born September 1, 1789, at Knockbrit, near Clonmel, Tipperary, where her father, Edmund Power, owned a small property. At the early age of fourteen she was forced into marrying a worthless Captain Farmer. She quitted him in three months' time, and in 1818, shortly after his death, married Charles Gardiner, Earl of Blessington. With him in 1822 she set out on a long tour on the Continent, where, as well as in London, she gathered around her all the most distinguished men of the time. In Genoa she formed an intellectual friendship with Lord Byron; afterwards she resided in

Paris, until the death of her husband in 1829. He left her a large fortune; and she held a little court of her own at her Kensington mansion, Gore House, Kensington, her celebrated soirees being frequented by many of her distinguished contemporaries. Her connection with Count d'Orsay (q.v.), which dated from 1822, placed her in an equivocal position as regards society, and her lavish expenditure overwhelmed her in debt, though for nearly twenty years she was making an extra income of more than £2000 per annum as author of a dozen most trashy novels. She was the authoress of *The Idler in France*, *The Idler in Italy*, and *Conversations with Lord Byron* (1834; new ed. 1894), which placed the poet in a more favourable light before his countrymen. At length in April 1849 she and D'Orsay had to flee from their creditors to Paris, and there on 4th June she died of apoplexy. See her *Life* by Madden (3 vols. 1855).

Bletchingley, an ancient town of Surrey, 5 miles N.E. of Reigate, which till 1832 returned two members to parliament, though now its population is under 2000. In the neighbourhood fuller's-earth is raised.

Bletchley, a railway junction in Buckinghamshire, 47 miles N.W. of London, 31 N.E. of Oxford, and 45 S.W. of Cambridge.

Blets, rotten spots in apples, pears, medlars, and other fruits.—*Bletting* is the first stage in the rotting of such fruits when the consistency of the fruit has altered, and the colour changed to brown, but before actual putrefaction has set in. The medlar is eaten in this state. See FRUIT.

Blewfields, BLUEFIELDS, ESCONDIDA, or RIO DEL DESASTRE, a river of the Mosquito Territory, in Central America, which, after a course of several hundred miles to the east, enters the Caribbean Sea in 12° N. lat. and 83° W. long. At its mouth is a good harbour, with a town of the same name.

Blicher, STEEN STEENSEN, Danish poet and novelist, born 11th October 1782, at Viim, a village of Viborg; studied at Copenhagen, became in 1819 pastor at Thorming, and in 1826 at Spendrup, in Jutland. Here he died, 26th March 1848. He was long known only as the successful translator of Ossian (1807-9), but his *Sneeklokken* (1826), and his *Jydsk Romancer*, which appeared in the monthly periodical *Nordlyset*, soon became widely popular. These, however, were eclipsed by *Nationalnoevler*, also published monthly, and noted by their remarkably sympathetic insight into the life of the people on the heaths of Jutland. Blicher's poems are thoughtful, tender, and eminently national. A humorous autobiography is prefixed to the collection of his *Gamle og nye Noevler* (7 vols. 1846-47).

Blida, a thriving town of Algeria, 32 miles S.W. of Algiers by rail, which was ceded to France in 1837. The orange orchards produce 50 million fruits a year, which are mostly exported to France, and there is some trade in cotton, raisins, grain, tobacco, copper, and cork-wood. It suffered from earthquake in 1825 and 1867. Pop. 10,628.

Bligh, WILLIAM, an English admiral, born of an old Cornish family in 1753 or 1754, and celebrated in connection with the mutiny of the *Bounty*. He sailed under Captain Cook in his second voyage round the world, and earned early a high reputation as a skilful seaman. In December 1787 he was sent by the British government, as commander of the ship *Bounty*, to Tahiti, which he reached about ten months later, to collect plants of the bread-fruit tree with a view to their acclimatisation in the West India colonies. During their six months' stay on the island, his men had become

completely demoralised, and in a few weeks mutilated under the overbearing temper and harsh treatment of their commander. On 28th April 1789, Bligh, with eighteen men, was cast adrift in an open boat but 23 feet long, with a small stock of provisions, and without a chart; while the mutineers turned their own course back to Tahiti, and ultimately settled on Pitcairn's Island. After almost incredible hardship, Bligh arrived at the island of Timor, near Java, on 14th June, having with infinite skill and courage sailed his frail craft for 3618 miles. 'Bread-fruit Bligh' was again sent out to collect bread-fruit plants, but though on this occasion he was more successful, the bread-fruit tree did not supersede the plantain in the West Indies. In 1805 he was appointed governor of New South Wales, but his conduct here was so harsh and overbearing as to cause universal dissatisfaction; and in January 1808, unable to tolerate his rule, the civil and military officers of the colony summarily terminated his government by arresting him. He was kept in prison by the colonists for two years. The officer who arrested him was tried in England and cashiered. After Bligh's return to England he was raised to the rank of admiral in 1811. He died in London, 7th December 1817.—The Bligh Islands are a portion of the Fiji Archipelago, in nearly 180° of long.

Blighia. See AKEE.

Blight, a diseased state of cultivated plants, especially cereals and grasses. The term has been very vaguely and variously used, having, in fact, been applied by agriculturists to almost every disease of plants in turn, however caused, especially when the plant dies before reaching maturity. See PLANTS (DISEASES OF).

Blimbing, or BILIMBI (*Acerrhoa Bilimbi*), an East Indian tree belonging to the Oxalidaceæ, cultivated in the Antilles for the sake of its wholesome and palatable fruit.

Blind. Blindness may arise from any cause intercepting the rays of light on their way to the optic nerve, or from disease of the optic nerve, or of that part of the brain connected with it. Blindness may vary in degree; it may exist from birth, or be the result of disease at any period of life. It may only be present during the day or the night, or a few weeks of the year, or it may be permanent. Only a few are born blind, although many lose their sight in infancy from preventable causes. One of the most frequent causes of blindness is the inflammation of the eyes of new-born babies, a disease which generally can be prevented, and always cured. In almost all blind schools in England and the Continent, a third, and even more, of the pupils' blindness is caused by the *neglect and unsuitable treatment of this disease*. Eminent oculists state that half the blindness in Europe is due to this inflammation of the eyes of new-born babies. (See publications of the Society for the Prevention of Blindness, 48 Wimple Street, London, W.). Many become blind by accidents, smallpox, scarlet fever, measles, whooping-cough, or the various diseases of the Eye (q.v.).

The man who loses his sight after having had full use of it for years is profoundly to be pitied. He has lost not merely that great gateway of knowledge, but it frequently happens that the loss of sight, for a time at least, shatters and enfeebles mental energy, and weakens the remaining senses and powers. Milton, blind himself, makes Samson say:

Now blind, disheartened, shamed, dishonoured, quelled,
To what can I be useful? wherein serve
My nation, and the work from heaven imposed?
But to sit idle on the household hearth,
A burdensome drone, to visitants a gaze,
Or pitted object.

The man born blind is in many ways still worse off: he cannot in the least imagine to himself what it is to be able to see; colour and visual form are unknown to him (see VISION). Locke's blind man who imagined that 'scarlet was like the sound of a trumpet,' made but a very random shot. Nor is it true that the blind man's other senses are preternaturally acute, and that blind people are always good musicians. A blind boy, under proper training, can indeed have his senses of touch and hearing developed to a state of exceeding acuteness, though they can never make up for the lost faculty. A blind boy who can read with the first finger of each hand, will be as unable as the seeing to use the other fingers for reading, unless he has practised with them. Without careful training and persevering industry, the blind cannot attain even creditable proficiency in music. Amongst blind men, some of them blind from infancy, who have more or less completely triumphed over their disadvantages or been otherwise famous, may be named Homer; Belisarius; John Milton; the Cambridge professor, Nicholas Saunderson (q.v.); Dr Blacklock; John Metcalf of Knaresborough, road surveyor (blind from six years of age); Holman, the blind traveller; Hüber, the naturalist; Prescott, the historian; Louis Braille; Sir George Macfarren; and Professor Fawcett. The blind have at various times suffered under special legal disabilities, for example as to acting as witnesses and as to succession to fiefs and thrones; by the canon law a blind man was disqualified for holy orders.

At four successive censuses the total number of blind was:

	1851.	1861.	1871.	1881.
England and Wales.....	18,306	19,352	21,590	22,832
Scotland.....	3,010	2,820	3,019	3,158
Ireland.....	7,587	6,879	6,347	6,111

At the same dates the number of the general population to each blind person was:

	1851.	1861.	1871.	1881.
England and Wales.....	979	1037	1052	1138
Scotland.....	1065	1090	1112	1182
Ireland.....	864	843	852	847

'In England, Wales, and Scotland, the proportion of blind to the whole population has decreased with each successive enumeration since 1851, in which year a special account of the blind was first taken; but the decrease in the decade ending 1881 was much greater than in either the preceding decennial intervals. The decrease may be fairly attributed to the progressive improvement in surgical treatment of affections of the eyes, and to the diminished prevalence of such diseases as smallpox, to which a considerable amount of blindness was formerly due. Another cause of decrease is probably the improvement of the health of the community due to better sanitation. Had blindness been as common in 1881 as in 1851, there would have been 26,523 blind persons in England and Wales, instead of 22,832, or 16·2 per cent. more than there actually were. Among the 22,832 blind persons enumerated were 1958 who, according to the returns, had been blind from birth. This, however, must be interpreted as including not only those who literally answered such description, but those also who had lost their sight at a very early age, for it appears to be an extremely rare thing for an infant to be actually blind at the time of birth.' In England and Wales the number of blind per million of the population was, in 1880, as follows: under 5 years of age, 166; from 5 to 15, 288; 15 to 20, 388; 20 to 25, 422; 25 to 45, 641; 45 to 65, 1625; 65 years of age and upwards, 6915. At the census of 1891 the number of the blind had again decidedly declined: in England and Wales the number was 23,467; in Scotland, 2797; in Ireland, 5341.

In the United States, in 1890, the number of the blind was 50,411; in 1880 there were in the United

States in all 48,928 blind persons, of whom 26,748 were males and 22,180 females. There were 40,599 of them native, 8239 foreign; and 41,278 were white, while 7650 were coloured, 244 Indians, and 22 Chinese. There was thus one blind person to every 1023 of the general population.

The following table shows the number of blind persons per million according to sex in different countries:

Country.	Male Blind per Million Males.	Female Blind per Million Females.
England and Wales.....	953	809
Scotland.....	865	827
Ireland.....	1141	1219
Denmark.....	776	793
Norway.....	1313	1411
Sweden.....	767	843
Finland.....	1514	2038
German Empire.....	884	881
Austria and Hungary.....	1280	1123
Holland.....	499	394
Belgium.....	982	641
France.....	948	726
Spain.....	1242	1911
Italy.....	1106	925

Institutions.—The first institution for the blind of which we have any record was a hospital merely, namely, that founded by St Louis at Paris in 1260, specially for crusaders who had lost their eyesight in Egypt. There have been many such hospitals, where no attempt at education was made. J. Bernouilli (q.v.) seems to have been the first to teach a blind girl to write (in 1657). But it was Valentin Haüy of Paris who in 1784 made the first successful attempt to educate the blind. To him is due the honour of instituting a movement which has resulted in the establishment of institutions for education, and workshops for the training and employment of the blind in all civilised countries. Before the end of the century the following institutions were opened in this country: School for the Indigent Blind, Liverpool, 1791; Royal Blind Asylum and School, Edinburgh, 1793; School for the Blind, Bristol, 1793; School for the Indigent Blind, London, 1799. Since the beginning of the 19th century many institutions for the blind have been opened in the United Kingdom. They may be divided into six classes, as follows:

1. Schools for Resident Pupils.....	14
2. A combination of School and Workshop.....	13
3. Workshops.....	21
4. Asylums.....	9
5. School and Asylum.....	3
6. Workshop and Asylum.....	1
Number attending Schools.....	1664
Number in Workshops.....	1168

School Boards.—In other countries the state provides for the education of the blind, but as yet the English government has not recognised its responsibility in regard to the education of the blind. A beginning has been made by the School Boards of London and some other large towns. The School Board of Glasgow was the first to take up this work, but the School Board for London subsequently took the lead, and adopted a comprehensive and systematic plan. A superintendent, specially qualified for the work, has charge of the training of all blind children under the London School Board. This superintendent has under her five blind teachers, trained at the Royal Normal College for the Blind. The blind children attend board schools, but receive special instruction at thirty centres, the classes varying from 1 to 15 in number, and the amount of teaching given weekly being proportioned to the size of the class.

Home-teaching Societies.—There are about 80 home-teaching societies in the United Kingdom; they are established in all the large towns, and the blind, even in country districts, are visited. 'The objects of the society are to visit the blind in their

own homes, to teach them to read by Moon's system (a few are also taught Braille), and when they have learned, to carry them books, which are changed at stated intervals. Some of the Scottish home-teaching societies attempt to start those whom they visit in trades, or otherwise enable them to maintain themselves.'

Indigent Blind Visiting Society (London).—This society, founded in 1834, has for its object to visit, educate, and relieve the blind at their own homes, independently of asylums. It is the great missionary society to the blind of London, of whom it assists about 900. It relieves pressing cases of temporary distress, assists those whose incomes are nearly, but not quite sufficient to live upon, and starts the blind in trade or business whenever it is likely they will succeed if assisted at the commencement. It has also day-classes in different parts of London, where the blind are taught to read and write. The women are taught knitting, &c., and employment is given them when they have learned.'

British and Foreign Blind Association.—In 1868 a number of blind gentlemen, being aware of the great improvements which had been made in the education and employment of the blind on the Continent and in America, founded the British and Foreign Blind Association for the purpose of promoting the education and employment of the blind, by ascertaining what had been done in these respects in this and other countries, and endeavouring to supply deficiencies where they were found to exist, and by attempting to bring about harmony of action between the different existing schools and institutions. The association soon gained information through its corresponding members of what was being done abroad, and published a report. The executive council of the association has not only endeavoured to induce the various institutions to adopt the best methods and systems of education, but has been indefatigable in its efforts to improve and cheapen the apparatus, books, maps, &c. used by the blind.

United States.—In the United States, the 36 institutions, with about 2500 inmates, are as a whole palatial in comparison with those of Britain. Every blind child has a right to be educated at the expense of the state. Some of the best institutions are, however, founded and maintained by private benevolence. Different schools use different systems of reading and writing; the Boston Roman letter, New York point type, Moon, pure Braille, and modified Braille being all in use.

The following table furnishes statistics for other countries:

	Number of Blind.	Blind Institutions.	Blind in Institutions.
German Empire.....	37,672	35	1811

In 1784 M. Valentin Haüy commenced the first printing in raised characters for the blind, and founded the Institution Nationale des Jeunes Aveugles, which was the first, and still holds its place among the best managed schools for the blind in the Old and New Worlds. The character he chose was the Italian, or written form of the Roman letter. Founts of types were cast and books printed; and having been approved by the

Academy of Sciences, and exhibited before the royal family at Versailles, the art created at the time a great sensation.

Gall's type.—Mr James Gall of Edinburgh saw specimens of Parisian books in 1826, and was deeply impressed with the importance of putting the Bible into the hands of the blind to employ their vacant hours. Being himself a printer and publisher, he resolved to improve the alphabet so as to make it more tangible. In 1827, after much study and many experiments, Mr Gall printed his 'first book' for teaching the blind to read, in a triangular modification of the common alphabet, of which the following is a specimen :

Β Ε Ι Ο Ι Δ † Η Ε Ι Δ Μ Β Ο † Γ Ο Δ

This was followed by other little volumes, including a series of Scripture statements and a condensed epitome of Old Testament history. These were received with so much favour, that in 1829 he issued a prospectus for the publication of the Gospel by St John, at one guinea, which was to pay not only for the copies, but preliminary expenses. This work was printed in 1832, but was not published until 1834. In 1832 the Scottish Society of Arts offered a gold medal, value £20, for the best alphabet for the blind. The award was not made till 1837. Sixteen arbitrary alphabets had been sent in, all of which were rejected, and the prize was awarded to a Dr Fry of London, who had suggested the use of Roman capitals, which were introduced in America in 1834. Great interest began to be excited throughout Britain, and extended even to foreign countries. Abbé Carton was sent by the Belgian government to visit Mr Gall's establishment, and returned to set up a printing-press in Brussels. Mr Gall was anxious to improve the printing and lessen the cost; the most important improvement consisted in the use of serrated types, by which the letters were formed of dots (.....) instead of lines. In 1836, therefore, he offered to societies and publishers to print books for the blind in the improved type at so much per sheet, as an ordinary business transaction, without either subscriptions or donations. Of this offer the London Sunday School Union, the Religions Tract Society, and the British and Foreign Bible Society availed themselves in 1837; and in 1838 he printed for the British and Foreign Bible Society the Gospel by St Luke and the Acts of the Apostles.

As the institutions for the blind in those days 'had not hitherto (as they expressed it) patronised any device of this kind,' Mr Gall had to contend with all the apathy and incredulity which every new thing has to encounter. But now the tide had turned; readers were multiplying over the country, schools for the blind were beginning to be formed, the institutions abroad had all 'patronised the device,' and printing-presses were busy both in America and on the Continent; so that when the Sunday School Union, the London Tract Society, and the British and Foreign Bible Society began to publish class-books, tracts, and Bibles for the blind, they all became convinced of its importance.

Howe's or Boston.—Dr Howe also, from Boston, visited Scotland, and having received from Mr Gall all the information which he could supply, established on his return to America a printing-press in the Perkins Institution. In 1834 he published the Acts of the Apostles, and completed the New Testament in 1836. About the same time Mr Friedlander of Philadelphia published the Gospel by St Mark. He unfortunately adopted the capital alphabet. Dr Howe, on the contrary,

had adopted an angular modification of the common alphabet, similar to, but much smaller than Mr Gall's, and with that printed the whole Bible, besides an ever-increasing number of other volumes in all departments. For many years Dr Howe supplied books for all the institutions in the United States.

Alston's.—Mr John Alston of Glasgow, who established a printing-press in the Blind Asylum, of which he was treasurer, printed in 1837 the Gospel by St Mark in the same type in which (unknown to him) it had been printed in 1834 by Mr Friedlander in Philadelphia. Through his influence it was at once adopted in the other institutions throughout the kingdom; and, having thrown himself with much enthusiasm into the work, he very soon raised funds by which he completed the New Testament in 1838, and the whole Bible in 1840. To him, therefore, belongs the honour of having printed the first complete Bible for the blind in any language, because Dr Howe of America, although he commenced the work earlier, did not finish it till 1842. The effect was immediate and decisive, rivalry was extinguished, hundreds of the blind were brought under instruction, and reading was thenceforth acknowledged to be a necessary department of the education of the blind. Mr Alston being encouraged by the decision of the Scottish Society of Arts, which he himself helped to influence, made a fatal error in adopting Roman capitals. Reaction very soon took place, the blind themselves being the first to rebel. The want of sufficient legibility was, in their judgment, a fatal objection, and outweighed all other considerations. Even the large amount of money that had been expended, and the extensive libraries that had been formed through Mr Alston's energetic labours, they were prepared to sacrifice, in order to obtain books which they could read with ease. Gall's Serrated Type is illustrated by

Bekold the Lamb of God

and Howe's American Type by :

behold the lamb of God

Lucas's.—In 1838 Mr Lucas of Bristol introduced an ingenious system of stenographic shorthand. It is still used by the London Society for Teaching the Blind to Read. The characters are altogether arbitrary, consisting mainly of lines with or without a dot at one end.

Frere's.—Mr Frere also introduced his phonetic shorthand system about 1838. The embossed characters were only an application of his phonetic system for the seeing, which he hoped would become general. His characters consist of straight lines, half circles, hooked lines, and angles of 45 degrees, together with a hollow and solid circle. Mr Frere also invented the 'return' lines—that is to say, the lines in his book are read from left to right, and from right to left alternately, the letters themselves being reversed in the return lines. He devised a cheap and very ingenious method of setting up and stereotyping his books. The letters, formed of copper wire, are laid on a tin plate, previously washed over with a solution of zinc; when heat is applied to the under-surface, the letter becomes soldered on to the plate, and such plates produce extremely good printing. Both Moon and Lucas adopted this system of stereotyping.

Moon's.—Dr Moon of Brighton, whose system is used more than any other by the adult blind throughout the country, adopted an arbitrary alphabet, some of the characters resembling or

suggesting the letters which they represent. He also adopted Mr Frere's return lines, but does not reverse the letters.

It has already been stated that the blind objected to the Roman capitals on account of illegibility. Towards the middle of the 19th century the intelligent blind in all parts of the world began a very earnest protest against the various line-types, which had been arranged with as much regard to the seeing as the blind. In a short time the question became one of dots *versus* lines. It was then that the great invention of Louis Braille was recognised. He had published a system in 1829, and fully developed it in 1834. His blind friends and co-workers immediately recognised its superiority over the Roman letter, but the school authorities of the Institution Nationale des Jeunes Aveugles would not change the old system. It was not officially adopted in Paris until 1854, two years after the death of its inventor.

Louis Braille was born in January 1809 at Combray, about 23 miles from Paris. He became blind through an accident at the age of three. In 1819 he became a pupil of the Institution Nationale des Jeunes Aveugles at Paris. In 1826 he was elected professor at the institution, where he had distinguished himself as a pupil. As a pupil and professor he laboured to invent a system which the blind could not only read, but write in relief. He had been trained as a boy to read the line type; after examining all systems, including arbitrary characters, he became convinced that the one best adapted to reading and writing was M. Barbier's. Barbier's letter contained six points, but was too long vertically to be covered with the finger. Braille worked upon it until he devised the simple and beautiful system which bears his name.

In regard to the necessity for readable and cheap books for the blind, in a character that can be written as well as read, Mr Wait, New York, says: 'Books are as necessary to the blind as to the seeing, and every reason which can be urged why there should be books cheap and plenty for all the seeing, applies with equal force with regard to books for the blind. The necessities of the blind in this respect have been and are urgent, and great efforts have been made to supply the want. But the institutions for the blind in or about which these efforts have generally originated have been so widely separated in regard to time of origin and place of location, that there has been little or no community of interest or of action. The result is that there are no less than eight distinct kinds of alphabet and printing for the blind, each being advocated as having advantages over every other. But if we may judge from the present condition of the art of reading amongst the blind, these alphabets, though produced by the most strenuous exertions and most praiseworthy zeal, have failed in their general utility, and do not answer the purpose for which they were intended. The reasons for this probably are that the principles upon which an alphabet for the blind should be constructed have not been sufficiently understood, and that the soundness of theories has not been properly ascertained by experiment.'

Statistics collected from seven institutions in the United States showed that of 664 blind persons under instruction, only 225, or 34 per cent., could read with facility; and 185, or 31 per cent., could read moderately well. As a whole, this table shows a marked uniformity in the general results obtained in the several institutions named. If under the most favourable conditions 35 per cent. fail to learn the alphabet of the Boston and Glasgow systems, it is plain that a large majority of all the blind, probably 70 per cent., can never enjoy the privilege of reading. It is a fact which

every candid observer must concede, that the systems of printing for the blind at present used in this country do not meet the wants of the blind.

'A trial of the point system proved conclusively, that those who cannot learn either the Boston or Glasgow print can learn the point alphabet. And it should be remarked, that while the ability to read those systems is lost by a short period of disuse, or by working at any business which hardens the cuticle of the fingers, such is not the case with the point alphabet. It can be read by any blind person of ordinary intellect, no matter what his business, nor how long the period of disuse. It is urged against the point signs, that they are arbitrary and unlike the signs used by the seeing. But there is in reality no force in this objection. The necessities of the blind grow out of their condition, and the true value of anything made for their use is found in the fact that it is adapted to their condition and meets their necessities, regardless of other considerations. Which is the more important, that all the young blind should be able to read—thus being made, in fact, like the seeing—or that they should be taught an alphabet which in some sort resembles that used by the seeing, but by doing which only 34 per cent. of them will ever be able to read with any pleasure or profit? The answer of every blind person and of every practical educator is obvious.

'The important point is that the blind shall be like the seeing in what they know and can do, no matter whether the means of knowing or doing be the same as are used by the seeing or not. But the point signs have other important advantages besides that of being easily learned at any time of life by any blind person. They can be used in writing music, keeping accounts, and transcribing books; so that in one and the same system the blind can read and write, thus relieving the memory of heavy burdens and enabling them to grasp a far greater range of subjects, or to engage more deeply and successfully in any given study or pursuit.

'Point signs have another great advantage, which is, that while they are used as letters, they can also be combined so as to represent whole words, abbreviations, and terminations; thus combining the features of the stenographic and alphabetic systems. The shorthand signs could be used in the books and writing of those taught in schools for the blind, while books for adults could be printed in the common signs of the alphabet.

'The values of the point and line systems, in regard to their susceptibility to the touch, may be stated as follows: Point-sign system, 95 per cent.; line-sign system, 48 per cent. This subject is discussed at great length in the report of the New York Institution for the Blind of 1868. Full information is also given in regard to the New York point.' (It should be observed that Mr Wait's experiments with line systems did not include Dr Moon's.)

Braille.—The Braille signs are arbitrary, and consist of varying combinations of six points placed in an oblong, of which the vertical side contains three, and the horizontal two points (: :). There are sixty-two possible combinations of these six points, so that after providing characters for the twenty-six letters of the English alphabet there remain a sufficient number of signs for punctuation, contractions, &c.

'The group of six dots, which is the largest number of points that any letter can consist of, is divided into upper, middle, and lower pairs. The first ten letters, from *a* to *j*, exhaust all possible combinations of the upper and middle points. The next ten, from *k* to *t*, are formed from the first by adding a lower back point to each. Thus, *a* becomes *k*, *b* becomes *l*, &c. The third row is

similarly formed by adding two lower points. Thus, *a* becomes *u*, *b* becomes *v*, &c.

THE BRAILLE ALPHABET, WITH CONTRACTIONS.

The large dots represent the raised points of the Braille letter; the small simply serve to indicate their position in the group of six.

The signs of the 2d, 3d, and 4th lines are formed from those of the 1st by the addition of lower dots.

‘The fourth row of letters is formed from the first by adding a lower front point to each of the first row. The only letter of the ordinary alphabet in this row is *w*, which is derived from *j* by adding a lower front point. It will be observed that *w* comes out of its usual place in the alphabet. This is because the original French alphabet has been adhered to; *w* not being a letter used in genuine French words, it was originally placed the last on the fourth row, and has been there retained, as placing it out of its usual position was considered a far less evil than altering the meaning of the last four letters of the alphabet.

‘Reading is also facilitated by the use of a few simple, well-chosen contractions, as words being rendered shorter, the finger has less space to traverse.’

It is interesting to know that in Egypt, where the blind are very numerous, the Koran has been printed in the Braille type, and a blind person can earn a good livelihood by reading the Koran at funerals and other occasions. In China there are many blind persons; and here Mr Murray, one of the Scottish Bible Society’s missionaries, has ingeniously adapted the Braille system for printing Chinese.

Braille Writing-frame.—‘For writing, a frame is used consisting of a grooved metal bed, containing ten grooves to the inch; over this is fitted a brass guide, punched with oblong holes, whose vertical diameter is $\frac{3}{16}$ ths of an inch, while the horizontal diameter is $\frac{1}{16}$ ths. This perforated guide is fixed into a light wooden frame, like the frame of a slate, which is attached to the grooved metal bed by hinges. The paper is introduced between the frame and the grooved bed. The instrument for writing is a blunt awl, which carries a little cap of paper before it into the grooves of the bed, thereby producing a series of little pits on the side next the writer. When the paper is taken out and turned over, little prominences are felt corresponding to the pits on the other side. The reading is performed from left to right, consequently the writing is from right to left; but this reversal presents no practical difficulty as soon as the pupil has caught the idea that in reading and writing alike he has to go forwards. The brass guide has a double row of openings, which enables the writer to write two lines; when these are written he shifts his guide downwards until two little pins, which project from the under surface at its ends, drop into corresponding holes of the frame, when the writer writes two more lines; and this operation is repeated until he arrives at the bottom of the page. This description applies to the writing-frame used in France and most parts of the continent of Europe.

‘The English frame is somewhat different. In it

ALPHABETS USED BY THE BLIND.

the bed is not grooved, but is marked by groups of little pits, each group consisting of six. These are arranged in two parallel lines, and the guide is hinged on this bed in such a way, that when the two are locked, the openings in the guide correspond exactly to the pits in the bed. When the first two lines have been written, the guide and bed travel as one piece down the board, which

is so arranged as to give the right distances between the lines. Each line is separated from the next by a wide interval, which greatly facilitates reading; when the first page has been written the paper is reversed, and the lines of the second page are written in the intervals between those of the first. A simple mechanical arrangement enables a blind person to do this with ease and certainty.

This interlined writing not only makes the writing far more legible than that produced in the original French frame, but also effects a saving of space amounting to about 20 per cent.'

New York Point.—A modification of the Braille, now known as New York point, is generally adopted in the United States. The long diameter of the full letter of six points is horizontal instead of vertical (: :), the letters recurring most frequently being represented by the smallest number of points.

Braille Musical Notation.—Braille furnishes a musical notation less complicated and easier to learn than the ordinary staff notation. Any music whatever can be written. In instrumental music a serious disadvantage arises from the fact that the blind performer has both to read and play with his hands; the usual plan is to read with one hand and play with the other, until the music is committed to memory. In vocal music this drawback disappears. During a performance before Her Majesty at Windsor by the pupils of the Royal Normal College and Academy of Music for the Blind, a musician present sent up a short composition in manuscript. It was dictated, quickly written, and sung from the notes with accuracy and effect by the blind choir.

Printing.—Embossed books are produced in various ways in France, generally from movable type. The printing for the English-speaking blind is done principally by the American Printing House for the Blind, Louisville, Kentucky, U.S.A.; the Howe Memorial Press, Perkins Institution for the Blind, Boston, U.S.A.; Dr Moon's Printing Establishment, 104 Queen's Road, Brighton; and the British and Foreign Blind Association, 33 Cambridge Square, London.

The American Printing House has an ingenious and very peculiar method of stereotyping from movable type; lack of space precludes a description. The press is worked by steam-power; four sheets are printed at a time, cut automatically, and delivered to the binder. The American Printing House has a subsidy of \$10,000 per annum from the American government, and the institutions in the United States have the right to order books in any type; practically, however, the books are only embossed in the Boston type and New York point. The Howe Memorial Press of Boston is a steam-press with vertical action, which prints one page at a time. The stereotyping is done from movable type by electrotyping. The cost is about double that of plates produced by the British and Foreign Blind Association. (Dr Moon's method has been referred to under types.) The British and Foreign Blind Association prints from brass plates. The frame for producing stereo-plates is very similar to the ordinary interlined writing-frame, only stronger. A sheet of brass folded upon itself is placed in the frame and embossed by means of a punch and hammer, in a similar way to that in which a style would be used in writing a single sheet of paper. The association plates are made by the blind themselves, without the intervention of movable type, and without any aid from seeing persons or skilled workmen. Both sides of the paper are printed at the same time by one pressure.

Dr Armitage, the indefatigable honorary secretary, says: 'After the most determined opposition, the Braille system, which is the foundation of all real education for the blind, has been pretty generally adopted by the schools of the United Kingdom, and the work of the association has, to a great extent, contributed to produce the same result in Germany. More books have been published in the Braille system, either in print or embossed by hand, by the association than exist in all other

systems put together. As the Braille system is generally adopted for music, and care is taken not to reproduce what is already in print in other countries, blind musicians have now a very large and varied library, which is daily extending. Books embossed by hand are also rapidly multiplying, as about forty paid blind writers and about twenty lady volunteers are constantly engaged on this work. The ladies emboss books in Braille from ordinary type for the seeing, and these are copied by the blind, who generally have no intelligent reader to dictate to them. Much improvement has taken place in the construction of maps and other school apparatus.'

Writing and School Apparatus.—Even a short description of each machine or piece of apparatus is impossible, but the following list may be of use: Writing frames—Elliott Brothers, Pooley's, Levitte's, Thurstield's, Moon's, Wedgewood's, Hebold's, Guldberg's, and Klein's. Dr Moon has paper with raised lines, and the British and Foreign Blind Association corrugated cardboard. Though expensive, type-writers as constructed for the seeing, with very slight modifications, can be used with equal facility by the blind. For writing with capital and lowercase letters, Remington's is the quickest and best; for capitals only, the Caligraph; and Hall's type-writer is very convenient and less expensive, but much slower. For working arithmetical sums many ciphering-boards have been constructed, but the best is the octagonal board introduced by the Rev. William Taylor of Worcester. For school purposes good and very cheap maps are produced by the British and Foreign Blind Association.

Trades.—The handicrafts which are usually pursued in the principal workshops of the United Kingdom are the making of baskets, brushes, brooms, bedding, mats, ship-fenders, ropes, sacks, chair-caning, wood-chopping, &c.; for girls, hand and machine sewing, knitting, netting, crocheting, &c. Of all trades, pianoforte-tuning is the best; but the blind can only succeed as pianoforte-tuners when they are first-class workmen. The plan pursued by the Royal Normal College is not to recommend any tuners who cannot pass the required examinations, and obtain an official certificate.

In the United States, broom-making, under favourable conditions, proves very remunerative (see reports of Home and Workshop for Blind Men, Philadelphia). The Germans have not adopted our workshop system for the blind, but the best institutions, especially of Saxony, continue to keep a methodical supervision over their pupils, even in the country districts, after they have left the institutions. It is claimed that by this system a much larger proportion of the blind become independent members of society. Active friends of the blind in all countries would do well to acquaint themselves with the details of the Saxony system.

Professions.—A considerable number of blind gentlemen have passed through the leading universities of Britain and other countries, and have won by their talents and energy honourable positions in the church, medicine, law, politics, and commerce. In 1888 an effort was being made in the United States to establish a special national university for the blind. Such a university must either be second-rate, or very costly. Even if the nation should be willing to pay the money to make it a first-class university, such a course will be regretted by intelligent blind men all over the world. They contend that a special university for a few blind students can never give them the privileges of existing universities, with their eminent professors, their libraries, associations, spirit of culture and progress, and, above all,

opportunities of coming in contact with the outside world, and forming lasting friendships with young men who will soon be busy actors in every walk of life. The blind ask not for a special university, but for scholarships in existing universities.

Music.—Music in its various branches offers the best and most lucrative employment for those among the blind who, from an early age, can have suitable educational privileges—an education which develops alike the body, mind, and musical talent. The Royal Normal College and Academy of Music for the Blind has shown by practical results what is possible in the profession of music. The education in the college is not limited to music: to a casual observer it would seem that music occupied almost a secondary place. The first aim is manly character, healthy bodies, well-cultivated and active minds, and prompt, business-like habits, which qualify its pupils for practical life. The pupils are taught swimming, skating, rowing, cycling, canoeing, gymnastics (Swedish, German, and American), military drill, and in the season a great variety of outdoor sports. The college embraces a preparatory school with classes in Kindergarten and modelling, a grammar and high school, a technical school, and an academy of music. The course of instruction includes the following departments: (1) General education, including the training of school teachers; (2) the science and practice of music, including the training of music teachers, pianists, organists, choir-masters, and vocalists; (3) technical education, including mechanical training and pianofortetuning.

For a hundred years noble men and women have laboured with untiring devotion for the education and training of the blind, and have desired to lift them as a class from pauperism; but the majority of mankind still bewail the sad lot of the blind, and only think of them with pity and commiseration. Even in countries where the government provides for the education of the blind, the institutions are charitable rather than educational. In a number of the American states the schools for the blind are no longer regarded as charitable institutions, are no longer under the control of the State Board of Charities, but in common with all schools for the sighted, are under the management of the Board of Education; consequently, in the United States, the blind as a class are in a better condition socially than the blind of any other country. Too much praise cannot be given to the noble philanthropists who have done so much for the blind; but the time has come when the nation ought to recognise the duty it owes to its defective classes. We need a comprehensive scheme which will not only harmonise existing agencies, but include government aid; which will at least provide employment for all the able-bodied among the blind, even if it does not make them entirely self-sustaining; which will give all the young blind who possess even ordinary ability that education and training best calculated to make them useful and independent members of society; which will grade the various institutions according to the age, capacity, and requirements of the pupils. Educational institutions should be entirely separated from workshops, but each educational institution should have a technical shop for preparatory training, and when the time arrives to decide the future career of the pupils, they should be drafted to the institution or workshop that will afford them the special privileges they require. There should be at least one special institution for feeble-minded children; at present this class of children must either be entirely neglected, or taken into the ordinary institutions, where they

are not only a hindrance, but exercise a deleterious influence upon the other pupils. Such a comprehensive plan of working would minimise the cost, and make the work in all departments more effective. But such a plan can only be instituted and carried out under national control.

See *Information with regard to Institutions, Societies, and Classes for the Blind in England and Wales*, by H. J. Wilson, Secretary to Commission of the Gardner Trust for the Blind, 1 Poets' Corner, Westminster: *A few Statistics in connection with the Blind of Scotland*, by W. A. Arrol; *A Guide to Institutions and Charities for the Blind*, by Mansfield Turner and Wm. Harris. For full and recent information in regard to the blind of all parts of the world, see *Education and Employment of the Blind*, a very comprehensive book by T. R. Armitage, M.D. Much of the information of this article is derived from Dr Armitage and Mr W. B. Wait, New York, who have done more than all others to introduce an educational type that can be both read and written by the English-speaking blind. See EYE, VISION.

Blind. KARL, author and revolutionist, was born at Mannheim in 1826, and studied law at Heidelberg. For his share in the risings in South Germany in 1848 he was sentenced to eight years' imprisonment, but while being taken to Mainz was liberated by the populace. After the reaction had again triumphed over the Continent, Blind found an asylum first in Belgium, and afterwards in England, where he has taken an active part in democratic propaganda. An enthusiastic advocate of German freedom and unity, he promoted the Sleswick-Holstein movement. As an author he has written on politics, history, and mythology, including lives of Ledru-Rollin, Deák, Freiligrath; also volumes and magazine articles on such subjects as Fire Burial, Yggdrasil, Water Tales, Shetlandic and Welsh Folklore, The Siegfried Tale, and The New Conflict in Germany.

Blind Fish. In situations where light is absent, blind animals are commonly found. The absence of the normal stimulus has necessitated cessation of function and various degrees of degeneration in structure. In most cases rudimentary traces of eyes prove the fact of degeneration; and that the latter is largely the direct effect of

Blind Fish of the Kentucky Caves (*Amblyopsis speleus*).

the absence of the stimulus preserving the health of the eye is allowed by most (see DEGENERATION). The blind fish of the Kentucky caves (*Amblyopsis*, q.v.) has degenerate hidden remnants of eyes; *Lucifuga dentata*, a very different form, found in the subterranean caves of Cuba (though member of a marine family), is also blind; the Hagfish (*Myxine glutinosa*), though perhaps hardly a fish in the technical sense, has also virtually lost its eyes in association with its habit of spending much of its life buried in the mud, or parasitically within eels and haddock; the primitive vertebrate, the Lance-

let (*Amphioxus*, q.v.), is in the same state. In the sea the eyes of fish are large in proportion to the depth inhabited, down to 200 fathoms; big eyes are needed to make the most of the scanty light. Below the light-limit large-eyed forms occur, probably utilising the gleams of phosphorescence, or small-eyed forms with greatly developed tactile organs. In the greatest depths, however, as the result of the *Challenger* Expedition demonstrated (see Gunther's *Challenger* Report on Fishes), fishes with rudimentary eyes occur, as one would indeed expect. See CAVE ANIMALS, ENVIRONMENT, FISHES.

Blind Harry. See HARRY.

Blindness. COLOUR. See COLOUR BLINDNESS.

Blindstory, another name for the Triforium (q.v.), so called as opposed to the Clearstory or Clerestory (q.v.) of a church.

Blind-worm, or SLOW-WORM (*Anguis fragilis*), a limbless lizard, in the Skink family. The form is worm-like, tapering slightly in the tail; only internal traces of limbs are present; the two girdles are very rudimentary; the tail occupies about half the total length; the nostril is situated in a shield; the eyelids are scaly and movable; the ear-hole very small and hidden; the teeth borne on the jaws are long, pointed, and directed backwards; the tongue is scaly in front, with slender warts behind; the scales are smooth, and those of the head very distinctive. The colour varies considerably with age; the young are whitish above with

Blind-worm.

a median black stripe, but black on the sides and below; the adults are brownish above and black below, often relieved by longitudinal lines. The full size is about a foot, about half of which goes to the tail, but large specimens may measure a foot and a half or more. The blind-worms are shy animals, living among bushes, and coming out at night in search of earth-worms and white slugs. They give a feeble bite, but are perfectly harmless. So timid are they that they become rigid when caught, and in this state an attempt to bend the greatly contracted muscles results in a breakage. The body divides in two, as the specific title *fragilis* implies. The young are born alive in mid-summer to the number of 8 to 26. In winter they hibernate in holes in the ground, not alone, however, but in companies of two dozen or so. The blind-worms are found all over Europe, except in Sardinia and the northern regions, and are also known in North Africa and Western Asia. They appear to be hardy animals, and have been found more than 3000 feet up the Alps. They occur, though not abundantly, in Britain. White of Selborne gives an interesting account of their habits. It need hardly be said that they have no special connection with serpents, though similarity of habit has come to be associated with a superficial external resemblance. As true lizards they must also be distinguished from the much rarer amphibian *Cecilia* (q.v.), to

which the name blind-worm is also sometimes applied.

Blister-beetle, a popular name for a number of beetles in a family of Coleoptera known as Vesicantia, or in two distinct families, Meloidae and Cantharidae. The name refers to the vesicating or blister-raising properties of their body-juice. The Spanish-fly and the Oil-beetle are familiar illustrations. As to the zoological characters of the family, the antennae are usually 11-jointed, the head depressed with a narrow neck, the front shield narrower than the flexible wing-covers, the claws split into two usually unequal portions, the abdomen with 6 to 7 free rings. They are usually brightly coloured, especially at home in warm countries, include about 800 species, and almost always possess the blistering property above noticed. The life-history is often very remarkable. The larvae live parasitically on bees, on grasshopper or locust eggs, &c., and seem to pass through an unusual number of changes, to which the name 'hyper-metamorphosis' has been applied. It is not merely that the larvae begin life lean, horny, and 6-footed, and soon become fat, soft, and footless, but that before passing into the pupa stage, they pass through a series of preparatory changes. The important genera are: (1) *Lytta* or *Cantharis*, (2) *Mylabris*, (3) *Cercocoma*, (4) *Meloë*. In regard to some of these, a few notes are requisite. (1) The genus *Lytta* or *Cantharis* has wings, long, thread-like, 11-jointed feelers, and kidney-shaped eyes. It includes over 250 species, of which only 8 are European. The most familiar form is the common blister-beetle or Spanish-fly, *Lytta* or *Cantharis vesicatoria*. This bright golden-coloured or bluish-green beetle is common on many trees in Europe. It makes its presence felt by devouring the leaves. The females lay a large number of eggs in a hole in the ground, whence, after 3 to 4 weeks, the larvae pass in all probability into certain bees. For medicinal purposes, the beetles are dried and rubbed into powder. The irritant substance is found throughout the body, but especially in the ovaries. (2) *Mylabris* is a rarer European genus, but includes even more tropical forms than *Lytta*, restricted, however, to the Old World. (3) *Cercocoma*, with 9-jointed feelers, is commoner in Europe; *C. schafferi* is indeed frequent. (4) *Meloë* is a large wingless genus, with about 70 species, represented everywhere except in Australia. The females have a very broad abdomen. They live in grass. On irritation, they allow an oily, yellow, blistering fluid to ooze out from between the joints. The common Oil-beetle (*M. proscarabaeus*) and another beautiful species (*M. variegatus*) are striking illustrations of romantic life-histories. For this and other particulars in regard to *Meloë*, see article under that head. Apart from their medicinal use, the physiology and life-history of these blister-beetles invest them with very considerable biological interest. The common blister-beetle, Spanish-fly or *Cantharis*, will be further treated at CANTHARIDES; and see below.

Blisters are medicinal agents which, when applied to the skin, raise the cuticle into vesicles filled with serous fluid. They are applied either in the form of plasters or in a fluid state, as suits the convenience of the person or part, and have for their object the establishing of a counter-irritation or diversion of inflammatory action from a part in which it cannot be reached by remedies, or from some organ where it may do permanent mischief, to some more superficial part of the body.

The most common blister in use is made of Cantharides or Spanish fly (*Cantharis vesicatoria*). Cantharides, mixed with a convenient proportion of lard and wax, form the blistering ointment in

ordinary use; the only objection to this preparation being, that if applied too freely, it produces much irritation of the kidneys and urinary bladder. In young children and very thin-skinned persons, a layer of silver paper, or thin gauze wet with vinegar, may be laid between the blister and the skin. But under no circumstances should a blister be left long upon children, as it may produce sores which are apt to take on an unhealthy action, and are difficult to heal.

Mustard (*Sinapis nigra*) is frequently used to redden the skin, but seldom left on sufficiently long to produce blistering. Tincture of cantharides, croton-oil, strong liquor ammonia, tartar emetic ointment, and many other drugs are used in practice.

If the occasion for the blister passes off, the vesicles should be pricked, and their fluid contents allowed to trickle away, the vesicated surface being then dressed with some cold cream or lard. But if it should appear desirable to promote a discharge from the skin, the raised cuticle may be snipped off, and some stimulating application such as savine ointment (*Juniperus sabina*) used to dress the raw surface. Great cleanliness should be observed in dressing the part.

Blisters are used for the relief of acute inflammation in internal organs—e.g. the pleura, lungs, membranes of the brain; for the dispersion of the products left by inflammation—e.g. in indolent ulcers of the skin, enlarged lymphatic glands, and chronically inflamed joints; and for the relief of pain, even where no inflammation is present—e.g. in many forms of neuralgia. To name all the conditions where blisters may be of use would mean an enumeration of more than half the diseases known to medicine and surgery.

Blister is also one of the names applied to a bleb on the skin filled with fluid, by whatever cause produced—friction, disease, &c., as well as by vesicants, or other medicinal agents. See BULLA.

Blizzard is a fierce storm of bitter frosty wind with fine blinding snow, in which, especially in the western states of the American union, man and beast often perish. In one which visited Dakota and the states of Montana, Minnesota, Nebraska, Kansas, and Texas, in January 1888, the thermometer fell within twenty-four hours from 74° above zero to 28° below it in some places, and in Dakota went down to 40° below zero. In fine clear weather, with little or no warning the sky darkened and was filled by snow or ice-dust as fine as flour, driven before a wind so furious and roaring, that men's voices were inaudible at a distance of 6 feet. Objects became invisible a few yards off. Farmers died in the fields ere they could reach their houses, and children on their way from school; some of those who died having been not frozen but suffocated, from the impossibility of breathing the blizzard. Some 235 persons lost their lives. This was the worst since 1864; the Colorado River in Texas was frozen with ice a foot thick for the first time in the memory of man. In some districts blizzards are looked for three or four times in a winter; but really disastrous ones are rare, those of 1836, of December 1863, January 1866, January 1873 being, till that of 1888, the severest on record. The word, which seems to be akin to *blast*, *bluster*, first became usual throughout the United States during the severe winter of 1880–81, but was in colloquial use in the West early in the century. See WIND and STORMS.

Bloch, MARCUS ELIESER, a celebrated ichthyologist, born of poor Jewish parents at Anspach, in Bavaria, in 1723. He settled in medical practice at Berlin, where his life was uneventful, and where

he died, August 6, 1799. He is chiefly remembered for his great work, the *Allgemeine Naturgeschichte der Fische* (12 vols. Berlin, 1782–95, with 432 coloured plates), long the most comprehensive work on ichthyology, and still valuable, especially for its illustrations.

Block, in the rigging of a ship, is an important part of the apparatus necessary for raising sails and yards, tightening ropes, &c. The block comprises both the frame or shell, and the pulley or pulleys—usually termed 'sheaves'—contained within it. In nautical and mechanical language a *tackle* includes the rope as well as the block through which it works. Ships' blocks vary greatly in size, shape, power, designation, and use, but nearly every block comprises a shell or wooden exterior, a *sheave* or wheel on which the rope runs, a *pin* or axle on which the sheave turns, and a *strap* (of rope or iron) to fasten the block to any particular station.

For very many years, the uniform practice was to bind the shells by straps of rope—hempen or wire—but in more recent times, only the smaller class of blocks are thus bound, and those of a heavy calibre are environed by a band of iron—sometimes inside the shell, and said to be 'inside ironbound,' and sometimes outside, when they are termed 'outside ironbound.' Ironbound blocks have been in use in merchant-ships for a much longer period than in government vessels, on board which modern improvements are often slow of being adopted. A single block contains only one sheave, a double block, two; a treble block, three; and so on; while the term 'purchase-block' is generally applied to all blocks having more than two sheaves. All the blocks on board ship have distinctive names—e.g. *cat-block*, *check-block*, *clew-garnet-block*, *clew-line-block*, *boat-block*, *snatch-block*, &c., according to the kind of service they have to perform, or to their place of fixing, while not a few names are examples of the odd and sometimes unaccountable nomenclature adopted by seamen.

Ships' blocks are usually made of elm, and the sheaves of lignum-vite, the hardest kind of wood procurable in any considerable quantity. The pins are of iron or steel, and the bushes or bearing parts of the sheave are usually of brass. Patent roller bushes, which allow the sheave to turn with minimum of friction, have for several years been largely adopted. The figures show examples of the blocks most commonly in use.

Blocks made wholly of iron (see PULLEY) are used to some extent about the decks of ships, but are ill adapted for use in ships' rigging, on account of the chafing and fraying of ropes and sails thereby entailed.

Until near the end of the 18th century blocks were all made by hand, and the trade was of considerable importance. For one of the old seventy-fours of the navy alone, more than 1400 blocks were required, and for vessels of larger or smaller size a proportionate number. The introduction of steam in place of the 'unbought wind' as a propulsive power, has materially reduced the number of blocks required on board ship, and the adoption of specialised labour-saving machinery has rendered

a, single 'outside ironbound' block;
b, double 'inside ironbound' block
(with swivel hooks).

their manufacture at the present time a matter of great ease and simplicity. Two men, comparatively unskilled, with the aid of the machines now in use, can produce as many complete blocks in one day as would have taxed the efforts of the skilled artificers of other days during the best part of a week. In 1781 a Mr Taylor began to make the sheaves and shells of blocks by a process which he had invented. He made all the blocks for the royal navy until the expiration of his patent rights. The Admiralty then commenced the manufacture on their own account. In 1801 Mr (afterwards Sir) Mark Isambard Brunel submitted to the Admiralty plans of a system of machinery for block-making, which was accepted, and the inventor engaged to set up the apparatus at Portsmouth. In 1808 the system was put into effective operation, it being found even then so perfect, that very few additions or improvements have since been needed. The machinery made blocks more accurately than they had ever been made by hand, and with the aid of ordinary workmen only. It could effect £50,000 worth of work in a year, or 140,000 blocks, by the assistance of ten men in attendance. Duplicate machinery was made for Chatham. Brunel received £20,000 for his invention and for his personal superintendence until the machinery was brought into working order; this sum was money well laid out, for the system saved to the country more than £20,000 a year, in the busy warlike period from 1808 to 1815.

Block. MAURICE, statistician, born at Berlin of Jewish family, 18th February 1816, studied at Bonn and Giessen, but settled at Paris, where for a time (1852-62) he held a post in the statistical bureau. He has published very many works on the statistics of France and Europe, including the *Annuaire de l'Économie Politique et de Statistique*.

Blockade. in a military sense, is an operation for capturing an enemy's town or fortress, often without a bombardment or regular siege. The attacking party throws up works on the neighbouring heights and roads, so as to guard every exit from the town. The rest of the besieging force remains under cover in villages, or in a temporary camp, ready to repel any sortie attempted by the besieged. The whole purpose in view is to prevent the besieged from receiving supplies of any kind, in order that, when the food or the ammunition is exhausted, they may be compelled to surrender. Fortresses situated on steep and rocky eminences, difficult to conquer by bombardment or assault, may often be reduced by blockade; because the roads or paths for the reception of supplies are few, and can be watched by a small number of troops. Towns situated on a plain are less easily invested; but if the inhabitants are numerous and commercial, they will soon be impatient of the restraint produced by a blockade, and compel the governor to surrender. When, therefore, resistance is determined on, the governor sends out of the town as many non-combatants as possible. He then collects all the stores in bomb-proofs, places the inhabitants on an allowance of food and under military rule, and endeavours, by frequent sorties, to prevent the besiegers from completing the investment of the place. A blockade should be the first step in a regular siege, and its effects may often be made more quickly felt by a bombardment. The blockade of Paris by the Germans in 1870-71 is the most notable example of such an operation that has ever been known. It was of itself completely successful, and the bombardment which was thought necessary might have been dispensed with. In this case a large civil population was blockaded together with a numerous army; but

at Metz, in the same campaign, a large and well appointed army, comparatively unhampered by the civil population, was compelled to surrender by a blockade without bombardment (see also SIEGE). Blockade on land depends on sovereignty or on military occupation. But at sea the rights of the neutral are *prima facie* equal to those of the belligerents.

Blockading, in a naval sense, is the prevention of the entrance or exit of the enemy's ships at a particular port, or at all the ports on a stretch of coast, so as to bring pressure to bear upon the inhabitants by obstructing their trade; and it renders intercourse with the enemy's ports unlawful on the part of neutrals. It is also sometimes an auxiliary to the military blockade by land. For a valid blockade it is necessary that a state of war should exist; that the blockade be really effective, that is to say, it must be maintained by a force sufficient to prevent access to the enemy's port, or at least to render approach hazardous; and neutral nations must be informed by the blockading power, either by official notification to all those powers, or by warning given to neutral vessels which approach the line of blockade. But when a blockade has become notorious, the knowledge will be presumed against any merchant-vessel which attempts to enter the blockaded port. Effective blockade is the principle laid down in the Declaration of Paris (1856), but this is construed more rigidly by continental nations than by England or the United States. Riga was effectively blockaded during the Crimean war at a distance of 120 miles. The French insist more than we do on formal notice. The blockading force may seize any vessel with its cargo trying to trade with the port, and send it home for condemnation; and if the vessel succeed in breaking the blockade, it may be pursued and captured by a belligerent, until it has reached its port of destination. That breach of blockade involves confiscation of the ship is admitted by all civilised nations. The cargo is not forfeited unless its owner is the owner of the ship, or was cognisant of the intended violation.

Napoleon's Berlin decree of 1806 declared the British Islands in a state of blockade (see CONTINENTAL SYSTEM).

The most memorable of recent blockades is that of the ports of the Southern States by the Federal government during the American civil war. The blockade was begun in April 1861, and, extending as it did to the whole of the southern coast and ports, was at first somewhat ineffective. Ultimately it was more rigorous and systematic; but to the last a considerable trade was carried on by swift steamers (many of them Clyde-built) through such blockaded ports as Charleston (the harbour of which was obstructed by sinking old ships and stones to assist the blockaders) and Wilmington. The risks were great. Hobart Pasha, who was a noted blockade-runner, says that more than 40 ships were captured out of 66 that left England and New York to run the blockade during the four years of the war. But the profits were enormous; Hobart sold in Wilmington for twelve shillings women's stays which he bought at threepence, and sold cotton in Liverpool for half-a-crown which in Wilmington cost him only twopence a pound. Besides those captured, many blockade-runners had to be run ashore or burnt to escape the cruisers. Nassau, in the Bahamas, was a great station for ships in the blockade-running enterprise. See CHARLESTON, NEUTRALITY, PRIZE COURT; Hobart Pasha's *Sketches from my Life* (1886); T. S. Taylor's *Running the Blockade* (1896); and as to the law, Twiss, Hall, Phillimore, Hazlitt, and Roche for England; Wheaton for the United States; Hautefeuille, Helfter, Gessner, and

Bluntschli for the continent of Europe; the collections of treaties; and the proceedings of the *Alabama* Commission. Lord Stowell's decisions in the prize court during the French wars may be said to form the substance of English law on this subject.

Blockhouse is a stockade or wooden wall, roofed in and loopholed. The timbers which form the walls may be laid horizontally or vertically. They must be bullet-proof (about a square foot in section), and covered outside with earth up to the loopholes, to prevent their being set on fire. A similar precaution is adopted for the roof. Where timber is plentiful, and an artillery attack not to be feared, blockhouses are useful defensive works, and under these conditions they have been much used in the backwoods of America. In more civilised countries they would only be used in mountain warfare or as keeps to redoubts in the plains. In the latter case they may be exposed to artillery fire, and require then a double row of stockading, with 3 feet of well-rammed earth between. A blockhouse may be of any size and shape. It forms a barrack for its garrison, and the guard beds are convenient as banquettes upon which the men stand to fire. If large, a blockhouse is generally cruciform in plan, so as to gain flank defence, or it may have an upper story projecting over the lower to enable men to fire through loopholes in the floor upon the attacking troops. The same object is sometimes attained by placing the upper story diagonally across the lower one. A ditch is excavated round the blockhouse to provide the earth which covers the woodwork, and also to prevent the enemy getting close enough to set it on fire. Stakes are planted in the ditch to make it difficult for the enemy to collect in it, and there rally for the final assault.

Block Island, formerly called Manisees, is situated in the Atlantic about 9 miles S. from Rhode Island, United States, to which it belongs. It is about 8 miles long, has a lighthouse at its north end, and contains the township of New Shoreham, a summer resort. A breakwater on the east side of the island forms a harbour of refuge. Pop. 1147.

Block-printing, the method of printing, or producing *Block-books*, from wooden blocks. See BIBLIA PAUPERUM, WOOD-ENGRAVING, PRINTING.

Block-system. See RAILWAYS, Vol. VIII. p. 558.

Blomfontein, the capital of the Orange River Colony (q.v.), stands on the Modder, in a high and healthy district, 200 miles W. by N. of Durban. It is connected by railway with Cape Colony and, since 1890, with Johannesburg and Natal. It is the seat of an Anglican bishopric and of sundry colleges, and has a good deal of trade, mainly in wool. During the war Bloemfontein was occupied by Roberts (May 1900), and here it was proclaimed that the Orange River Free State had become a British colony. Pop. (1900) 12,000 (2800 coloured).

Blois, the capital of the French department Loir-et-Cher, has a remarkably fine situation on a steep acclivity, and is built chiefly on the right bank of the Loire. The old town, with its crooked, narrow streets, is mainly on the hill, crowned by the historic castle; the new business town, with fine quays, is near the river. An eleven-arch bridge (1717), 1000 feet long, unites the town with its suburb of Vienne on the left bank. It is 36 miles S.W. of Orleans. Blois has a cathedral; but its chief glory is its old castle, which has been the scene of many interesting historical events. Louis XII. was born in it; and under its roof Charles, Duc d'Alençon, and Margaret of Anjou, and Henri IV. and Margaret of Valois were married. Here also the Duc de Guise and his brother, the

cardinal, were murdered, by order of Henri III., 23d December 1588. Isabella, queen of Charles VI., here found a retreat; it served as a prison for Mary de' Medici; Catherine de' Medici died within its walls; and Maria Louisa here held her court in 1814, after Paris had capitulated. The castle was then neglected and used as a barrack; since 1845, but especially in 1880-87, a great part of it has been finely restored at great cost. Blois is a place of great antiquity. Stephen, who usurped the crown of England on the death of Henry I., was a son of one of the counts of Blois, by Adela, the daughter of William the Conqueror. Other celebrated natives have been Peter of Blois, subsequently archdeacon of London, and author, who died in 1200; and Denis Papin (q.v.), to whom a statue has been erected. Blois is an archbishop's see, and has manufactures of porcelain and gloves, with a trade in brandy, wine, and wood. Pop. (1886) 16,881.

Blomefield, FRANCIS, the topographer of Norfolk, rector of Hargham and Fersfield, and afterwards of Brocckdish, was born at Fersfield, 23d July 1705, and died 16th January 1752. The great achievement of his life was his *History of Norfolk*, which, though abounding in errors, is a vast storehouse of information on the subject. In 1735, while collecting materials for it, he discovered the 'Paston Letters.' The first volume appeared in folio in 1739, the second in folio and quarto in 1745; Blomefield died ere the completion of the third volume, which, with a fourth and fifth by the Rev. C. Parkin, appeared at Lynn (1769-75; new ed. 11 vols. London, 1805-10; index, 1862).

Blomfield, CHARLES JAMES, Bishop of London, was born in 1786 at Bury St Edmunds, in Suffolk, where his father was schoolmaster. Thence he passed to Trinity College, Cambridge, of which he was elected a fellow; and taking orders in 1810, he became incumbent of St Botolph, London (1819), Archdeacon of Colchester (1822), and Bishop of Chester (1824), whence in 1828 he was translated to London. Blomfield's reputation for classical scholarship rests on his editions of Æschylus, Callimachus, Euripides, &c. He was exceedingly active in the superintendence of his diocese, and was an originator of the movement for the erection of new churches, setting about the building of fifty at once. He died 5th August 1857. See the Life by his son (2 vols. 1863).

Blommaert, PHILIP, a Flemish author, with Conscience a reviver of the Flemish tongue, born at Ghent in 1809. In 1834 he published a volume of verse; but he rendered better service to literature and to the patriotic cause by his editions of *Theophilus* (1836), an old Flemish poem of the 14th century, and of the *Oudclamsche Gedichten* (3 vols. 1838-51) of the 12th, 13th, and 14th centuries. His most important work is a history of the Belgians (1849), in which he shows that the Low Countries, spite of political separation, have a unity of culture, and that the political welfare of Belgium is opposed to a French alliance. He died at Ghent, August 14, 1871.

Blondel, a celebrated French minstrel of the 12th century, born at Nesle, in Picardy, was a favourite of King Richard the Lion-heart, and accompanied him to Palestine. When, in 1193, Richard on his homeward journey was seized and imprisoned by Leopold, Duke of Austria, the minstrel wandered through Germany in disguise seeking his master, and at length came to the castle of Dürrenstein, in Austria, in which he heard that there was some illustrious captive. He placed himself under the tower and commenced singing a love-song which Richard and he had composed together. Hardly had he finished the first stanza,

when a well-known voice from the tower took up the second, and carried it on to the end. So the minstrel discovered his monarch, and, returning with all speed to England, was the means of his being ransomed by his subjects. Unfortunately, this story rests solely on the French Chronicle of Rheims, belonging to the latter half of the 13th century; its popularity dates only from Gretry's opera (1784). The poems that have come down to us under Blondel's name are poor and uninteresting; they are published by Tarbe in the *Collection des Poètes Champenois* (vol. xix. Rheims, 1862).

Blondin. CHARLES, rope dancer, born 24th February 1824, at St Omer near Calais, his real name being Jean François Gravelet; and, trained at Lyons, was soon known as 'The Little Wonder.' After making a several years' tour of the United States, on 30th June 1859, before a crowd of 25,000 persons, he crossed the Falls of Niagara on a tight-rope in five minutes; on 4th July he crossed blindfold, trundling a wheelbarrow; on 19th August he carried a man on his back; on 14th September 1860 he crossed on stilts in the presence of the Prince of Wales. His engagement at the Crystal Palace in 1862, where he performed on a rope 249 yards long, and 170 feet from the ground, drew immense crowds. After several years' retirement, he reappeared in 1880, and died at Ealing, 23d February 1897.

Blood. the nutritive fluid of the tissues and the great carrying tissue of the body, is the well-known red fluid which fills during life the arteries and veins of the body. It consists of an almost colourless fluid, the *liquor sanguinis* or *blood-plasma*, in which float a large number of small corpuscular bodies, the *blood-corpuscles* or *blood-globules*. The proportion of these to each other by weight is about one-third corpuscles to two-thirds plasma. The quantity of blood in the body by weight is about one thirteenth part that of the whole body. When a drop of blood is examined under the microscope, the corpuscles floating about are seen to be of two kinds, distinguishable chiefly by their colour—the white and the red. The white are very much fewer in number than the red, the proportion in healthy blood being about 1 to 355. Even in health, however, this proportion is subject to considerable variations, and still more so in disease; in some forms of disease (e.g. Leucocythæmia) the white corpuscles almost equalling in number the red.

The *white corpuscle* is a pale granular-looking body, containing in its centre a small round nucleus. In common with all simple cellular bodies, it possesses the power of altering its shape from time to time, by alternately shooting out and withdrawing small processes from its substance, a movement to which the term *amoeboid* is given from its resemblance to what is seen in the simple organism the *Amoeba* (q.v.).

The *red corpuscles*, on being withdrawn from the body, tend to run together into heaps resembling piles of coins or *rouleaux*. Their peculiar colour is due to the presence of a special colouring matter (*hemoglobin*). It is only when in bulk that they appear red and give the blood its characteristic red colour; the individual corpuscle itself is not red, but has more of a pale straw or fawn tint.

Throughout the animal kingdom two forms of red corpuscles are to be found. In man and in all other mammals, with the single exception of the camel in which the shape is elliptical, the red corpuscles are minute circular discs, flattened on each surface, and entirely devoid of any central kernel or nucleus. Each surface presents a slight hollowing out or depression, which gives rise to the shaded appearance seen in the centre of the corpuscle when viewed from its flat surface. In all

other vertebrate animals, including birds, reptiles, amphibians, and fishes, the red corpuscles are oval in shape, and contain a large central oval nucleus, the presence of which gives rise to a bulging in the centre of the corpuscle when viewed from its edge.

The red corpuscles of the blood vary much in size in different animals. In each species of animal they are always of uniform size. The corpuscles of mammals generally are much smaller than those of birds, those of reptiles and amphibians being still larger. In man the average size of the red corpuscle is about $\frac{7}{2500}$ inch. The largest corpuscle of all—about $\frac{1}{100}$ inch in diameter—is to be found in *Protos* (q.v.).

The number of corpuscles present in even a drop of blood is to be estimated by millions. In certain conditions of disease (e.g. Anæmia) the number may be reduced by one-half, one-third, or even more. They are formed in the spleen and red bone-marrow, probably also in the lymph glands, their exact mode of origin, however, being as yet obscure.

Composition of the Blood.—The red corpuscles are almost entirely made up of the colouring matter of the blood—hemoglobin; but contain in addition a very small proportion of albuminous bodies, with lecithin and cholesterol. Of the salts contained in them, the most abundant are those of potassium.

The composition of the plasma is much more complex than that of the corpuscles. In addition to water, of which it mainly is made up, it contains albumens, fats, traces of sugar, and a large number of extractive bodies and salts. As regards the salts contained in it, the most important feature is the preponderance of the sodium salts over those of potassium.

The composition of the blood-plasma varies considerably at different times and under different conditions, according to the waste matters thrown into it from the tissues, or derived by absorption from the alimentary canal.

Coagulation of the Blood.—One of the most remarkable properties of the blood, and one which at all times has excited great interest and attention, is the property it possesses of 'clotting' or 'coagulating' on being withdrawn from the body. In the vessels of the body the blood is in a fluid condition; but shortly after being withdrawn, instead of remaining fluid, it becomes viscid and gelatinous, and finally 'sets' into a firm jelly-like mass, so that the vessel containing it can be inverted without any of it escaping. If it be now set aside for a few hours, a clear somewhat straw-coloured fluid gradually separates from this mass, and collects between the clot and the sides of the vessel in which it is contained. This gradually increases in quantity till finally the blood is divided into two portions, a firm red *clot*, which retains the shape of the vessel, floating free in a clear, transparent, straw-coloured fluid—the *blood-serum*. Coagulation is not a simple cooling of the blood, as was formerly supposed. On the contrary, it is delayed by cold; and by surrounding the blood with ice it can be prevented altogether. The rapidity with which it takes place varies considerably in different cases. It can be entirely prevented by the addition to the blood of various salts, especially those of sodium and magnesium. The blood

a, Human red blood-corpuscles as seen from the surface and from the side; b, human red blood-corpuscles forming *rouleaux*; c, white blood-corpuscle; d, red corpuscles of the frog's blood, seen from the surface; d', the same as seen from the side.

remains fluid within the blood-vessels in virtue of some property possessed by their walls. Even after death the blood may remain an indefinite time without coagulating; but on being withdrawn from the blood-vessel it at once coagulates.

The clot which forms as the result of coagulation retains the shape of the vessel into which the blood has been poured, and presents usually a cup-shaped depression on its upper surface. It consists almost entirely of the red corpuscles of the blood entangled in a meshwork of fine fibrils or threads, which are composed of a substance termed *fibrin*. This substance does not exist as such in the living blood, but is formed at the moment of coagulation by the action of a body also formed at the moment of coagulation—the *fibrin-ferment*—on one of the chief constituents of the plasma—*fibrinogen*; the original blood-plasma thus separates into a solid and a fluid portion, the former (*fibrin*) entangling in its meshes almost all the corpuscles, the latter (the serum) escaping free. By 'whipping' the blood—i.e. beating it up with a stick, coagulation is hastened, and at the same time the fibrin is removed from the blood in the form of a tough stringy mass; the remaining blood is then made up solely of the red corpuscles floating in the serum.

In former times, when blood-letting was so much practised for the relief or cure of disease, much importance was attached to the appearances presented by the blood after being withdrawn, and more especially to the appearance of the clot which formed. When the blood coagulates slowly, time is given for the red corpuscles, which are the heavier, to fall to the bottom, the white corpuscles then forming a paler layer at the upper part of the clot. The appearance of this paler layer—the so-called 'buffy coat'—was thought to be of great significance, as indicating the existence of inflammations, and the patients were repeatedly bled, with a view to its removal. Little or no importance is now attached to such appearances. The colour and consistence of the clot, whether redder or paler, firm or more gelatinous, are entirely dependent upon the previous condition of the blood—its richness in blood corpuscles, or the poverty of its plasma in solid constituents.

Functions of the Blood.—The blood is the great carrying tissue of the body. As such its functions are of a three-fold nature: (1) it conveys the food-material to all the tissues of the body; (2) removes thence the waste-products; and (3) its red corpuscles are the great carriers of oxygen, without which the act of respiration could not be carried on. The blood going to the tissues (arterial blood) is of a bright red colour, due to the presence of a large excess of oxygen obtained in the lungs; whereas the blood returning from the tissues back to the heart and lungs (venous blood) is of a dark purple colour, its oxygen having been removed from it in the tissues, and a large quantity of carbonic acid having been added to it.

The red corpuscles possess great powers of absorbing oxygen, solely from the presence of the colouring matter in them—the hæmoglobin. This substance, one of the most complex found in the body, attaches oxygen to itself in a loose form in the lungs, and then delivers it up to the tissues. This is the change which occurs in the blood during breathing, the dark venous blood returning from the tissues, poor in oxygen and rich in carbonic acid, giving off its carbonic acid in the lungs, and again taking up fresh oxygen from the air, to return once more to the tissues as bright arterial blood. The highly important function of the white corpuscles, the leucocytes, in attacking and absorbing harmful and other microbes, is dealt with at PHAGOCYTES (q.v.). See RESPIRATION, ARTERIES, CIRCULATION, VEINS; also ANTISEPTIC SURGERY,

BACTERIA, BLEEDING, BLOOD-STAINS, GERM (for the germ theory of disease), INOCULATION, MALARIA, PYÆMIA, TRANSFUSION, WOUNDS.

In the early ages of society it was looked upon as the duty of the next of kin to avenge the death of a murdered relative; but among some primitive peoples, as the modern Bedouins, as among the ancient Anglo-Saxons, the right is annulled by compensation. The Mosaic law placed it under regulations, prohibiting the commutation of the penalty of death for money, and appointing *cities of refuge* for the involuntary manslayer. The wilful murderer was, in all cases whatever, to be put to death without permission of compensation (see CITY OF REFUGE). For the blood-feud, see VENDETTA. The eating of blood was prohibited by the Old Testament. Christians have generally regarded the prohibition as having ceased with the reason for it, and consider the exhortation of the apostolic council of Jerusalem to the Gentile converts, to abstain 'from things strangled and from blood,' to have been merely an application of the great law of Christian charity to the circumstances of a transition period, with reference to the prejudices of Jewish converts. Jews still always kill their own butcher-meat.

Blood. THOMAS, adventurer, was born in Ireland about 1618, and in the Great Rebellion sided with the parliament. Deprived of his estate at the Restoration, he put himself in 1663 at the head of a plot to seize Dublin Castle and Ormonde, the lord-lieutenant. On its discovery his chief accomplices were seized and executed; but he himself escaped to Holland, and was there received with high consideration. He soon found his way back to England to try what mischief might be brewed among the Fifth-Monarchy men; and thence proceeding to Scotland was present at the battle of Rullion Green (1666). On the night of 6th December 1670, the Duke of Ormonde was seized in his coach in St James's Street by a gang of bravoës, tied on horseback behind one of them, and hurried away towards Tyburn. The timely approach of his attendants at the moment when, in struggling with his riding-companion, he had succeeded in bringing him to the ground, probably saved the duke from hanging. Blood was the leader in this daring villainy. His next enterprise was still wilder and more dangerous. On 9th May 1671, disguised as a clergyman, with three accomplices he entered the Tower, determined to carry off the regalia. After nearly murdering the keeper of the jewels, he actually succeeded in getting off with the crown under his cloak, while one of his associates bore away the orb. They were pursued, however, seized, and committed to the Tower. Now came a singular turn of fortune. At the instigation of Buckingham, who was accused of having hired Blood to attack the Duke of Ormonde, King Charles visited the dauntless miscreant in prison, and, dreading the threat that there were hundreds of Blood's associates banded together by oath to avenge the death of any of the fraternity, pardoned him, took him to court, restored him his estate of £500 a year, and raised him so high in favour that for several years Colonel Blood was an influential medium of royal patronage. He quarrelled, however, with Buckingham, and was committed by the King's Bench on a charge of slander against him; he was bailed out, but died on 24th August 1680. See T. Seecombe's *Lives of Twelve Bad Men* (1896).

Blood-bird of New South Wales (*Myzomela sanguinolenta*), a species of Honey-eater (q.v.) (Meliphagidae), so named from the rich scarlet colour of the head, neck, breast, and back of the male. A very similar species is found in Bengal.

Blood-flower (*Hemeranthus*), a genus of Amaryllidaceæ (q.v.), mostly natives of South Africa, some of which are common in greenhouses. They take their name from the usual colour of their flowers, which form a fine head or crowded umbel. The bulbs are sometimes propagated by cutting them across above the middle, so as to stop the single growing point; new axillary bulbs then form around the outer edge. The species seem generally to possess poisonous properties. The inspissated juice of *H. toxicarius* is used in South Africa for poisoning arrows.

Bloodhound, a variety of Hound (q.v.), remarkable for its exquisite powers of scent, and for the eagerness with which it tracks a bleeding animal; it is able to select a freshly-wounded deer from among a herd, and follow its trail; and from this faculty it derives its name. It was also formerly called, both in England and Scotland, *sleuth-hound* or *sleuth-hound*, from the Middle-English *sleuth*, 'a slot or track' (Icel. *sloth*). The bloodhound was formerly common and much in use in Britain, as well as on the continent of Europe for hunting purposes, being in the possession of most noble families, who vied with one another in the purity and excellence of their different strains,

Bloodhound.

but is now rare, though Lord Wolverton, who died in 1887, at one time hunted a pack of bloodhounds in Dorsetshire. Bloodhounds were also much used to track escaped prisoners, and are mentioned in the poetical histories of Bruce and Wallace as being used by their enemies to discover them; and in later days they were resorted to by slave-owners in America in the pursuit of fugitive slaves. The bloodhound is a large tan-coloured dog, with an exceedingly handsome and noble head expressing dignity and strength. The head should be long and narrow, with a dome-shaped skull, the occipital bone forming a peculiar peak on the back of the skull; the eyes distinctly showing the third eyelid or 'haw', which gives the eye a bloodshot and rather fierce look; the ears long enough to meet in front of the nose, but falling down close on either side of the face; colour, a rich tan with a dark saddle, showing no white if possible. The bloodhound is rather unmanageable when thoroughly roused, on account of his courage and strength, but when properly treated is generally docile, and makes a capital watch-dog. Many interesting anecdotes are recorded of the perseverance and success of bloodhounds in following a track upon which they have been set, even when it has led them through much frequented roads. As recently as 1876 an unsuccessful attempt was made at Blackburn to track a murderer by means of a bloodhound.—THE CUBAN BLOODHOUND, notorious as having been employed

in the pursuit of felons and of fugitive slaves in Cuba and the slave-holding states of the American Union, differs largely from the true bloodhound, and is really the descendant of mastiffs with a bulldog cross, inferior to the real bloodhound in scent and all but ferocity; it is also called the Cuban mastiff. According to Powell (*The American Siberia*, 1892), foxhounds, specially bred and trained, are used for man-hunting in nearly all the convict-camps of Florida, &c. For the true bloodhound's kin, see TALBOT.

Blood-poisoning is a name loosely used of Pyæmia (q.v.) and allied diseases (see DISSECTION WOUNDS, POISON, WOUNDS). It is also used popularly in a wider sense for the results on the human system of poison germs from malaria, bad drains, &c.; or for the condition of the blood caused by such ailments as Bright's disease of the kidneys, &c. See GERM, HYGIENE, MALARIA, PTOMAINES, TYPHOID FEVER, &c.

Blood-rain, which doubtless has its origin in the up-rushing currents of waterspouts and whirlwinds, has frequently fallen in Italy and Southern Europe, and has been repeatedly traced, through the microscope and chemical test, to the sandy deserts of Northern Africa adjoining. Similar rains have fallen in the Canaries, and they may be likewise ascribed to the African desert to the eastward. In these cases the origin is the rainless whirlwinds of these arid deserts, which are locally called 'devils.'

Blood-root. See GEUM, HEMODORACEÆ, and SANGUINARIA.

Blood-stains. DETECTION OF, an important subject in connection with forensic medicine. On criminal trials the guilt of prisoners has frequently been established by the discovery of these stains. The following scheme shows the various methods employed in the investigation:

Visual—aided by *a*, ordinary lens; *b*, microscope; *c*, spectroscope; *d*, artificial light.

Chemical—*a*, heat—*positive*: (1, change of colour; 2, coagulation); *b*, ammonia—*negative*; *c*, hæmatin test; *d*, guaiacum test.

Blood when liquid stains all articles with which it comes in contact. It sinks into woven textures and such material as soft wood, but on metallic surfaces and on hard woods it forms a film of greater or less thickness, and quickly dries. At first it is of a reddish-brown colour, but in the course of a few weeks this deepens and becomes almost black.

Looked at with a lens of low power—say 10 or 20 diameters—the blood, if in any quantity, and coagulated, and if it has not sunk into the texture of the cloth, is observed to present an irregular surface, and entangled in it have frequently been detected foreign materials which have afforded a clue to the culprit, and to the manner in which the crime has been committed. Thus hairs, fragments of cotton, epithelial scales from the throat, and minute fragments of birds' feathers have often been noted. This preliminary investigation concluded, the attempt is now made to discover the peculiar corpuscles of the blood (see BLOOD). This is a matter of great difficulty when the blood has stained such articles as linen or cotton stuffs and become dry, but when spilt on hard surfaces, or when it is in such quantity as to form a distinct coagulum, the corpuscles are generally easily determined by the following process. The object is, by breaking up the coagulum, to dissolve out the corpuscles in some medium as nearly as possible of the same density as the *liquor sanguinis* of the circulation. Numerous media have from time to time been proposed, such as solutions of sugar, phosphate of soda, iodide of potassium, &c., but the one generally employed is a solution of glycerine in

water of specific gravity 1.028. If this solution be applied, for example, to the stained blade of a knife, or if a minute portion of dried blood-clot be gently dissolved in it, a reddish fluid is obtained which under a high power of the microscope (300 diameters) rarely fails to exhibit numerous corpuscles which by their peculiar appearance (see BLOOD) are at once recognised to be mammalian blood-discs. In the case of stained linen, &c., there is greater difficulty. The stained portion must be thoroughly moistened with the solution, and then squeezed over a glass rod. When the reddish fluid reaches the surface, it must be removed with the blade of a knife, placed on glass, and submitted to the microscope. By this simple process, unless the stain be of great age, its character is determined. Human blood in these circumstances, however, cannot be distinguished from the blood of the other members of the great class of the mammalia, with the solitary exception of the camel tribe, which present an oval blood-corpuscle (see CAMEL).

Of late years, the interesting fact has been discovered that blood possesses a distinct spectrum, so that it is possible to determine that a reddish fluid is really blood, although the corpuscles may not have been discovered owing to their accidental destruction. The stained portion of cloth or a portion of blood-clot is digested in distilled water, and as the result a liquid of a reddish colour is obtained. This should be placed in a deep narrow cell and examined by a spectroscopic eye-piece with a low power of the microscope. Two dark bands make their appearance, one in the middle of the green rays, and the other at their junction with the yellow. These are highly characteristic of the presence of the blood of some red-blooded animal. See SPECTRUM, and SPECTROSCOPE.

Lastly, under this head of the visual detection of blood, the presence of blood-stains may unexpectedly be discovered with artificial light, by examining the furniture and especially the walls of an apartment on which blood has fallen. During the day the spots of blood remain undetected, but at night, and with artificial light, they are clearly visible. It is especially on papers with dark-blue figuring that this interesting fact has been observed.

The chemical relations of blood are very definite. All stains due to blood are soluble, and this fact enables us at once to distinguish them from insoluble stains which closely resemble them, and which have frequently been mistaken for them, such as paint and ironmould. The stain to be examined is cut out and suspended by means of thread in a glass tube filled with distilled water. Should the stain be at all recent, it immediately dissolves, and long filmy streaks of colouring matter are discharged and descend in wavy lines to the bottom of the tube, where ultimately a stratum of reddish fluid of greater or less intensity is collected. The clear supernatant fluid is poured off, and the coloured portion is divided into two parts. One part is boiled, and if the fluid contain blood, the following peculiar changes take place. The colour is discharged, the redness disappears and gives way to a grayish green, and in addition a distinct coagulum is formed. Both these changes are highly characteristic of blood. Should some liquor potassie be now added, the coagulum is redissolved, and shows a green colour by reflected light. This may be described as a positive test of the presence of blood. The action of ammonia supplies us with a valuable negative one. If this volatile alkali be added to a solution of blood, no change of colour is produced. All other soluble stains are more or less altered in colour, such as those from the juices of fruits, &c., which have frequently been mistaken

for blood, and thus have given rise to grave suspicions. Experiments were made in France to form a fluid which in its chemical reactions, it was expected, could not be distinguished from blood. Mixtures of madder and other colouring matters with white of egg were proposed, but while they coagulated with heat, there was no alteration in the colour of the liquid. If a particle of dried blood can be removed from a weapon or any surface, an attempt may be made to prove that it is blood by the formation of blood or hæmatin crystals. The procedure is as follows: the particle is placed on a microscopic glass slide and moistened with glacial acetic acid. The glass is now gently heated over a spirit-lamp, when ebullition occurs, the blood particle dissolves, and ultimately a reddish-brown stain is left. If this stain is examined by the microscope, peculiar prismatic crystals are visible among the dried debris.

Lastly, in several interesting medico-legal cases where it was suspected that articles of clothing had been washed in order to obliterate the traces of blood, its presence has been determined by its reaction with the resin of guaiacum. On the suspected site of the blood-stain are placed a few drops of a spirituous solution of guaiacum freshly prepared. The resin is at once observed to separate on the surface of the cloth; if to this is now added a small quantity of peroxide of hydrogen, a beautiful sapphire-blue colour is struck.

Such are the chief means employed to detect blood. It is important to remember that they do not enable us to distinguish human from other mammalian blood—with the exception already mentioned—nor arterial from venous, nor male from female, nor adult from that of the young; but the blood-discs of birds and cold-blooded animals generally, from their size and other peculiarities, cannot be mistaken for those of man.

The standard works on medical jurisprudence are those of Taylor, *Principles and Practice of Medical Jurisprudence* (3d ed. 1883); Guy and Ferrier (5th ed. 1888); Woodman and Tidy; Orfila, *Médecine légale*; Briand; Caspar; Hoffman.

Bloodstone, a dark green stone spotted with red; see HELIOTROPE. Also a name for red hematite and ironstone.

Blood-worm, a name given by anglers and others to the very abundant aquatic larva of a gnat-like Dipterous insect known as *Chironomus plumosus*. This is the commonest of a large number (195) of British species, and the larva is very frequent in stagnant water. It has a worm-like appearance, a blood-red colour, and is used for bait. The development of *Chironomus* is of great biological interest on account of the very early isolation of those elements which are to form the future reproductive organs of the insect. Before the cells of the dividing egg have had time to change at all, these future reproductive rudiments are set apart, and as they do not share in the future changes of development, they must obviously preserve intact the constitution of the parent, and hand it on to the next offspring. See HEREDITY.

Bloomer Costume, a ladies' dress partly resembling male attire, which arose out of what is termed the 'Woman's Rights Movement' that began to be agitated in the United States about the year 1848. About the same time, and in close connection with this movement, arose an agitation for the reform of female attire. In 1849 Mrs Bloomer (who died 31st December 1894) adopted the costume to which she has given her name, and lectured on its advantages. The Bloomer dress consisted of a jacket with close sleeves, a skirt falling a little below the knee, and a pair of Turkish trousers. Though a few ladies followed

the example of Mrs Bloomer, the dress was extremely unpopular, and exposed its adherents to a degree of social martyrdom which the more prudent, timid, or amiable declined to brave. Dress reformation societies and private persons have from time to time advocated changes in the costume of women less radical than Mrs Bloomer's, especially a knickerbocker dress for bicycling.

Bloomery, the first forge through which iron passes after it has been melted from the ore, and where it is made into blooms. See IRON.

Bloomfield, ROBERT, the author of *The Farmer's Boy* and other pastoral pieces, born 3d December 1766, at Honnington, near Bury St Edmunds, was the son of a poor tailor, who died when Robert was a year old, leaving his wife to struggle with a school, where the future poet learned to read. At the age of eleven he was hired to a farmer, but ultimately became a shoemaker in London, where he wrote his *Farmer's Boy* in a poor garret. Through the efforts of Capel Loft it was published in 1800, had extraordinary popularity, and was translated into a number of languages. He subsequently published *Rural Tales*, *Wild Flowers*, and other pieces. The Duke of Grafton interested himself in his behalf and gave him a small allowance. He made Eolian harps, wrote poetry, and embarked in the book-trade, but failed. Latterly his health broke down, he became hypochondriac and half blind, and he died in poverty at Shefford, in Bedfordshire, 19th August 1823. See his *Remains in Prose and Verse* (1824); and W. H. Hart's *Selections from Correspondence* (1871).

Bloomington, capital of McLean county, Illinois, 126 miles S.W. of Chicago, is an important railway centre, and has a brisk trade and large railway-works, with foundries, furnaces, and coal-mines. There is a Wesleyan university in the town; and near it is the Illinois Normal University (450 students), in connection with which there is a state laboratory of natural history. Bloomington has a court-house built of Illinois marble, a Roman Catholic academy, and the Major College for women. Pop. (1860) 7075; (1890) 20,485. There is another Bloomington, a post-village lying between the branches of the White River, 60 miles S.W. of Indianapolis, in Indiana, seat of the Indiana University. Pop. 4018.

Blount, CHARLES, deist, was born at Upper Holloway, London, 27th April 1654. He became noted for his contributions (often but flippant) to the political, literary, and theological controversies of the times, some of his works being *Anima Mundi*, a translation of the first two books of *Apollonius Tyranus*, *Great is Duanu of the Ephesians*, *Tanua Scientiarum*, and *Vindication of Learning*. His miscellaneous works, with preface by Gildon, appeared in 1695. Despairing of marriage with his deceased wife's sister, he died by his own hand in 1693. The material of Blount's volumes was chiefly borrowed from other writers; but his contributions to freethought had an influence on the deistical movement.

Blount, THOMAS (1618-79), was called to the bar, but lived and died a country gentleman on Orleton, his estate in Herefordshire. A zealous Catholic, he was author of some sixteen works, the best known being *Ancient Tenures of Land and Feudal Customs of some Manors* (1679; new ed. 1815).

Blouse, the French name for a loose, sacklike over-garment somewhat answering to the English smock-frock. France is pre-eminently the country of blouses, ordinarily blue, worn not only by the country-people, but by workmen in towns.

Blow, JOHN, composer, born about 1648, became organist of Westminster Abbey in 1669, and of the Chapel Royal in 1676. For the stage he wrote a masque, *Venus und Adonis*, in which Mary Davis sang the part of Venus before Charles II.; and he was author of many birthday, New Year, and St Cecilia odes, about one hundred anthems, and fourteen services. His contemporaries thought him the 'greatest master in the world' in organ playing, and unprejudiced critics now consider his music in many respects in advance of his age, and as displaying great power and individuality. He died 1st October 1708.

Blow-fly, or FLESH-FLY (*Sarcophaga carnaria*), an insect of the order Diptera ('two-winged'), (q.v.), and of the large family Muscidae, of which the common House-fly, Blue-bottle (q.v.), &c. are familiar examples. It is very similar to these in general appearance; the body is hairy, the expanse of its wings about one inch, the face silky and yellow, the palps black, the thorax gray with three black stripes, the abdomen of a shining blackish brown, which, in

Blow-fly.

certain points of view, assumes a bluish tint, checkered with glittering yellowish spots. One of the distinguishing characters of the genus is, that the eyes are widely separate in both sexes, but in colour, hairiness, and shape of abdomen the males and females differ slightly. The multiplication is as usual rapid (one female may produce 20,000 larvae); some species produce their young alive (viviparously); the larvae feed (as the generic name suggests—Gr. *sarc*, 'flesh,' *phago*, 'I eat') on the flesh of living or dead animals; the insect passes the winter in the pupa stage. The adults are common in Britain on heaths, in gardens, copses, &c.; and the larvae are to be found feeding upon meat, the carcasses of animals, sometimes upon living earthworms, and too frequently upon sheep, of which it is one of the most grievous pests, requiring the constant attention of the shepherd during most of the summer and autumn. Some districts are more infested with it than others; it is particularly troublesome in the fenslands of England. Unless the maggots are removed, they eat into the skin, the sheep suffer great torment, and soon die. At first they may be removed by shaking them out of the wool, into which dry sand is then abundantly sprinkled; but if they are very numerous, a mercurial ointment or wash of corrosive sublimate is applied; and when the skin is much broken, the wool is clipped away, an ointment of tar and grease is used, and a cloth sewed over the part.

Another of the numerous species of this genus, common in Britain, is *S. mortuorum*, so named from its frequenting burial-vaults and laying its ova on corpses. It is very similar to the blow-fly, but the abdomen is of a shining steel blue, and the palps, feelers, and head are reddish brown. There

are altogether about 50 European species of *Sarcophaga*.

Blowing-machines. The earliest blowing-machine was, doubtless, some form of the common bellows, the idea of which is supposed to have been derived from the lungs. A very primitive form of this instrument is still in use in some Eastern countries, consisting simply of the skin of some animal sewed into a rude bag with a valve and nozzle.

Bellows.—The domestic bellows are worked by drawing the boards apart, when air is sucked in by the valve, to replace the vacuum which would otherwise be formed; and then, when the boards are being closed, the valve, which only opens inwards, is shut by the compressing of the air; so that at the latter, having no other escape, is forced out at the nozzle.

The great fault of the common bellows is, that it gives a succession of puffs, and not a continuous blast. One remedy for this was to use two bellows, so that one was blowing while the other was filling; but it was afterwards found that the double-bellows secured a still more uniform blast. This machine, shown in fig. 1, is merely the common bellows with

Fig. 1.—Section of Double-bellows for a Portable Forge.

a third board of the same shape as the other two placed between them, so as to form two chambers instead of one. The middle board is fixed, and both it and the lower one have valves placed in them opening inward. A weight on the lower board keeps the under chamber filled with air; and when this board is raised by a lever or otherwise, the air which it contains is forced into the upper chamber. The exit-pipe is attached to the latter, and a weight is placed on the upper board sufficiently heavy to press the air out in a continuous stream, the continuity being maintained by the large quantity of air always present in the upper chamber, and the uniform pressure of the weight. Even with the double-bellows, however, the blast is not quite regular.

Bellows made entirely of wood except the nozzle, first made in Germany in the 16th century, are in use in some continental countries, but they are only a modification of the common bellows.

The Chinese have a very simple form of bellows, shown in fig. 2, which is not only interesting in

Fig. 2.—Chinese Bellows.

itself, but also because its action is almost the same as the blowing-engine. It is merely a square chamber of wood, with a close-fitting piston, which, when drawn from the nozzle, opens the valves, *v*, *z*, to admit air, and when pushed in

the opposite direction, shuts these valves, and forces the air out by the nozzle.

Blowing-engines.—For iron blast-furnaces and for Bessemer steel converters, blowing-engines of large size are employed. In the former, the strength of the blast is usually, in this country, from 3 to 4 lb. per square inch, sometimes it is 6 lb., and in the United States it is used at as high as 10 lb. For the Bessemer Converter (*q.v.*), where a much greater pressure is required, it occasionally reaches 30 lb. per square inch. A general view of a blowing-engine is given in the article IRON. It consists in its simplest form of a steam-cylinder, an air-cylinder, and a large air-chamber, to insure a uniform blast. Sometimes the latter is dispensed with, and large main-pipes used instead. We shall merely describe the blowing-cylinder here. It is marked X in fig. 3, and is of

Fig. 3.—Section of a Blowing-cylinder, Shelton Iron-works, Stoke-upon-Trent.

cast-iron, with an air-tight piston, P, which, as it ascends and descends with the motion of the engine, alternately inhales and expels the air at each end. To effect this, a series of valves are provided, and these are arranged as follows: Inlet valves are placed on the top of the cylinder at A, and also on three sides of the box at B, but on the fourth side of this box there are two outlet valves at C. These valves consist of numerous openings, against which leather flaps lie when they are shut. Valves of a similar nature are placed at the bottom of the cylinder; those for the inlet of air at D, E, and F; and those for outlet at G. When the piston descends, it would create a vacuum in the upper portion of the cylinder, provided there were no openings in it; but the external air pressing on the inlet valves, opens them, and fills the space above the piston; at the same time, the outlet valves at C, which only open outwards, are tightly closed by the air pressing inwards from the pipe, M. Again, when the piston ascends, it compresses the air above it, and exactly reverses the action of the valves; that is to say, it shuts the inlet valves at A and B, opens the valves at C, and allows the compressed air to pass along the outlet pipe, M,

which is made of large size, so as to offer as little resistance as possible to the passage of the air. The valves at the bottom of the cylinder work exactly in the same way, the inlet valves, D, E, and F, opening when the piston ascends, and shutting when it descends, thus compelling the inhaled air to pass into the pipe, M, by the lower outlet valves at G. The air is conducted by the pipe, M, into a receiver of large capacity, which serves to equalise the blast before it passes to the tuyeres. See IRON, fig. 1.

A blast-engine at Shelton Ironworks, of which the blowing-cylinder is 8 feet 4 inches in diameter, and has a 9-foot stroke (represented in fig. 3), working with 186 horse-power, and making say 32 single strokes of the piston per minute, inhales 15,700 cubic feet of atmospheric air per minute; but this is compressed by the blowing-cylinder to a pressure of 3 lb. per square inch above the atmosphere, which reduces the volume supplied by the cylinder to 13,083 cubic feet. Its volume, however, is largely increased again, when raised to the hot-blast temperature, before entering the furnace. See Percy's *Metallurgy*, vol. ii.

Among the finest blowing-engines in England are those belonging to the Wigan Coal and Iron Co., and are situated at Kirkless Hall, near Wigan.

Fig. 4.—Trompe, or Water-blowing Machine (vertical section).

They were designed by the late Robert Wilson of the Bridgewater Foundry, near Manchester. Three pairs of engines are used, each pair consisting of a high and a low pressure steam-cylinder. The blowing-cylinders, six in number, are placed directly over the steam-cylinders, each of the

former being 8 feet 4 inches in diameter with a stroke of 12 feet. One of these blowing-cylinders weighs 25 tons. Valve gear of ingenious construction admits of the engines being worked at different speeds to suit the number of blast-furnaces in operation.

Trompe.—In the Catalan forges of Spain, the south of France, and some parts of America, there is a very ingenious water-blowing machine in use called a *Trompe*; but it can only be advantageously employed where a fall of a few yards of water is available. Its construction will be understood by an inspection of fig. 4. A strong wooden cistern, C, to act as a reservoir for the water; wooden pipes, P (generally two in number), through which it descends; and a wind-chest, W, to allow the air and water to separate, constitute the essential parts of the apparatus. It is put in operation by lifting the wedge *v* with a lever; this allows the water to rush down the pipe, and in doing so, draws in air through sloping holes, *a, a*, called aspirators, at the throat of the pipe. A continuous current of water and air is thus supplied to the wind-chest, which is provided with an opening at *o* for the escape of the water, while the air passes out in a regular stream by the nozzle-pipe at *n*. The height from which the water falls determines the tension of the blast; but the height seldom exceeds 27 feet, which gives a pressure of from $1\frac{1}{2}$ to 2 lb. to the square inch. The separation of the air from the water is greatly promoted by the current impinging on the platform, *p*.

Fans.—The fan is another machine for producing blasts of air. It is employed for such purposes as the melting of pig-iron in foundries and for forge fires. It is also used as an exhaust to withdraw foul air from mines, public buildings, and ships. For mines it is occasionally of a very large size (see VENTILATION). The winnowing of corn is another application of it. The common blast-fan is shown in fig. 5. It is like a wheel with the

Fig. 5.—Fan (vertical section).

arms tipped with vanes or blades, *v, v, v, v*, instead of being joined by a rim, and it is placed usually in an eccentric position, inside a chest, *c*, with central openings on each side for the admission of air, one of which is shown at *o*. It is generally driven by steam-power, and as it revolves, air is sucked in at the centre, drawn towards the tips, and impelled forward through the exit pipe, *e*.

Blast-fans seldom exceed 3 feet in diameter. The number of revolutions made per minute ranges from 700 to 1800; but the pressure of the fan-blast does not usually go beyond 6 ounces per square inch for ordinary foundry cupolas. Schiele's fan has numerous curved blades, and is nearly noiseless. It does not require much power to drive it, and has been very much used. Lloyd's fan has also curved blades, but they are fewer in number than in Schiele's. B. F. Sturtevant of Boston is the inventor of a fan with twelve curved blades,

and with conical annular discs on the same axis. This form is very much liked in the United States (see the *Engineer* for 1883 and 1884).

Rotary Pressure Blowers.—These are machines introduced in comparatively recent years. They act by regular displacement of the air at each revolution, since their pistons or drums closely fit their cases. In this respect they differ from fans, because, although there were no outlet for the blast, a fan could be kept revolving, but in such a case a pressure blower would stop. The rotary blower by Roots of Connersville, Indiana, is one of

Fig. 6.—Roots's Rotary Blower.

the best known, and is now very largely used for producing blasts in metallurgical operations, as well as for other purposes, in America and Europe. Its most improved form, patented in England in 1885, is shown in fig. 6. A pair of horizontal shafts traverse a case of the form of two semi-cylinders, separated by a rectangle equal in depth to the diameter of the semi-cylinders, and in width to the distance between the centres of the shafts. These shafts carry a pair of solid arms or pistons, the relative positions of which are maintained by external gearing at both ends provided with safety coverings. Each has a section somewhat resembling a figure of eight, and the action of which, as they revolve, takes the air in by an aperture at the bottom of the machine, and expels it with considerable pressure, if required, at the top. It gives a much greater pressure of blast than is attainable by the fan.

Another excellent machine of this kind, designed by J. G. Baker of Philadelphia, is employed for the same purposes as Roots's. It has a central drum with two vanes fairly fitting the two ends and the bored semi-cylindrical top of the case. Two lower drums, crescent-shaped in section, work by external gears at double the velocity of the central drum, the vanes of which move successively through the opening in each of the lower drums. The latter turn so as alternately to form abutments to prevent escape of air from either the entrance or delivery side. These rotary blowers produce blasts from a few ounces up to 3 lb. per square inch.

Blowpipe, a small instrument used in the arts for glass-blowing and soldering metals, and in analytical chemistry and mineralogy, for determining the nature of substances by the action of an intense and continuous heat. Its utility depends on the fact, that when a jet of air or oxygen is thrown into a flame, the rapidity of combustion is increased, while the effects are concentrated by diminishing the extent or space originally occupied by the flame.

The blowpipe generally consists of a conical tube of metal, about 8 inches long (see fig.), closed at the wider or lower end, but open at the narrow or upper end, which latter constitutes the mouthpiece, and

is turned over to admit of the lips closing perfectly round it. Near the lower end, a small tube, fitted with a finely perforated nozzle, *a*, is inserted in the large tube—the space below being intended as a chamber for condensing the moisture of the breath, and through this nozzle, a fine current of air can be projected against the flame experimented with.

Blowpipe.

The use of the mouth blowpipe, so as to sustain a prolonged steady blast, requires some skill, and is at first very fatiguing to the learner. In breathing, the manipulator involuntarily closes the back of the mouth, retaining in the expanded cheeks sufficient air to last till the lungs have been replenished through the nose. Where high temperatures are required mechanical blowpipes are resorted to.

When a current of air from the blowpipe is directed against a candle or gas-jet, the flame almost entirely loses its luminosity, owing to the perfect combustion of the gases evolved from the source of heat, and is projected in a lateral direction, as a long pointed cone, consisting of three distinct parts. The first or central cone is of a dark-blue colour, and there the combustion is complete from the excess of air thrown in from the small nozzle. The second cone, or that immediately surrounding the first, is somewhat luminous; and here the oxygen being insufficient for the combustion of the carbon, any metallic oxide subjected to the action of this portion of the flame is deprived of its oxygen, and reduced to the condition of metal; for this reason the luminous cone is generally termed the *reducing flame* of the blowpipe. Beyond the second cone, or where the flame comes freely in contact with the atmosphere, and abundance of oxygen is present to effect complete combustion of the gases, is a third, or pale yellow envelope, containing excess of atmospheric air at a very high temperature, so that a portion of metal, such as lead or copper, placed at this point, becomes rapidly converted into its oxide; this outer part of the flame is on this account called the *oxidising flame* of the blowpipe.

Substances under examination before the blowpipe are generally supported either on wood-charcoal or platinum—the latter in the condition of wire or foil. In applying the blowpipe test, the body to be examined is either heated alone, or along with some flux or fusible substance; this being added, in some cases, for the purpose of assisting in the reduction of metals from their ores and other compounds: in others, for the production of a transparent glassy bead, in which different colours can be readily observed. When heated alone, a loop of platinum wire, or a piece of charcoal, is generally employed as a support; the former when the colour of the flame is to be regarded as the characteristic reaction, the latter when such effects as the oxidation or reduction of metallic substances are to be observed.

The following are examples of the difference in colour communicated to the flame by different

substances: Salts of potash colour the flame *violet*; soda, *yellow*; lithia, *purplish red*; baryta, *yellowish green*; strontia, *carmine*; lime, *brick red*; compounds of phosphoric acid, boracic acid, and copper, *green*. The commonly occurring metallic oxides reducible by heating on charcoal alone in the inner flame of the blowpipe are the oxides of zinc, silver, lead, copper, bismuth, and antimony; the principal ores not so reducible are the alkalies and alkaline earths, as also the oxides of iron, manganese, and chromium. The fluxes generally used in blowpipe experiments are either carbonate of soda, borax (baborate of soda), or the ammoniac-phosphate of soda, otherwise called *Microcosmic Salt* (q.v.). The carbonate of soda, when heated on platinum-wire in the oxidising flame, forms with silica a *colourless glass*; with oxide of antimony, a *white bead*, &c. The following metals are reduced from their compounds when heated with carbonate of soda on charcoal in the inner flame of the blowpipe: viz. nickel, cobalt, iron, molybdenum, tungsten, copper, tin, silver, gold, and platinum. When compounds of zinc, lead, bismuth, arsenic, antimony, tellurium, and cadmium are similarly treated, these metals are also formed, but being volatile, pass off in vapour at the high temperature to which they are exposed.

Borax, as a flux, is generally mixed with the substance under examination, and placed on platinum-wire. When thus heated in either of the flames, baryta, strontia, lime, magnesia, alumina, and silica, yield *colourless beads*; cobalt gives a *fine blue colour*; copper, a *green*, &c. With microcosmic salt, the results obtained are generally similar to those with borax, and need not be specially mentioned, as the test is applied in the same way. The blowpipe has been long used by goldsmiths and jewellers for soldering metals, and by glass-blowers in fusing and sealing glass-tubes, &c.; it has also been applied in qualitative analysis for many years, but more recently chemists (especially Plattner) have devoted their attention to its use, and have even employed it with great success in *quantitative* chemical analysis; the advantages being that only a very small quantity of material is required to be operated upon, whilst the results may be obtained with great rapidity and considerable accuracy.

The *oxyhydrogen blowpipe* is an arrangement by which a jet of oxygen and hydrogen, in the proportions to form water, is ignited and directed against any object. The most intense heat is produced, most of the metals being volatilised when placed in it, and even the diamond changes into ordinary carbon, and is burned when exposed to its flame. When a cylinder of quicklime is heated by it, a most dazzling light is produced, rivalling the electric light in brilliancy, and known as the Drummond Light (q.v.).

Blowpipe, a kind of weapon much used by some of the Indian tribes of South America, both in war and for killing game. It consists of a long straight tube, in which a small poisoned arrow is placed, and forcibly expelled by the breath. The tube or blowpipe, called *gravatana*, *puema*, &c., is 8 to 12 feet long, the bore not generally large enough to admit the little-finger. It is made of reed or of the stem of a small palm. Near Pará, it is in general very ingeniously and nicely made of two stems of a palm (*Triarctea setigera*) of different diameters, the one fitted into the other. In some places the inner tube is formed of the thin stem of a reed, protected by an outer one of this palm. A *sight* is affixed to it near the end. The arrows used in that district are 15 to 18 inches long, made of the spines of another palm, sharply pointed, notched so as to break off in the wound, and their points covered with *Curari* (q.v.) poison. A little soft

down of the silk-cotton tree is twisted round each arrow, so as exactly to fit the tube. In Peru, arrows of only $1\frac{1}{2}$ to 2 inches long are used, and a different kind of poison seems to be employed. An accidental wound from one of these poisoned arrows not infrequently proves fatal. In the hand of a practised Indian, the blowpipe is a very deadly weapon, and particularly when directed against birds sitting in the tops of high trees. As his weapon makes no noise, the hunter often empties his quiver before he gathers up the game, and does more execution than an English sportsman could with his double-barrelled fowling-piece. In Borneo, the Dyaks have a similar blowpipe called a *sumpitan*. It, however, has an iron spear-head tied on the end so that it can be used as a spear. It is employed both in war and hunting. Small arrows, which have on their end a piece of pith adapted to the bore of the tube, are used. These are pointed with sharp fish-teeth and poisoned with upas. They are blown with great accuracy; and if the upas-juice is fresh, a wound from an arrow, fired at a distance of 40 yards, proves fatal to man. See POISON.

Blubber. See WHALE.

Blücher, GERHARD LEBERECHEIT VON, Prince of Wahlstadt, Field-marshal of Prussia, was born at Rostock, in Mecklenburg-Schwerin, December 16, 1742. In 1757, shortly after the commencement of the Seven Years' War, he joined a regiment of Swedish hussars, and in his first action was taken prisoner by the Prussian hussars, whose colonel persuaded him to exchange out of the service of Sweden into that of Prussia, and gave him a lieutenancy. He attained the rank of captain, but his dissipated habits lost him the favour of his colonel, who promoted a younger officer over his head, and Blücher, in 1772, left the service in disgust. He retired to his estate of Grossraddow, in Pomerania, and for fifteen years devoted himself to farming. In 1793, having returned to the army, he fought, as colonel of hussars, against the French on the Rhine, evincing great genius as a leader of cavalry. The breaking out of the war of 1806 led him, as lieutenant-general, to the battle of Auerstädt. He, with the greater part of the cavalry, occupied the left flank of the Prince of Hohenlohe's army in the retreat to Pomerania. Blücher himself marched into the territory of the free town of Lübeck, and hastily fortified the city; but the French took it by storm, and he was forced to surrender at Ratkau, whither he had escaped with a few troops. A fortnight after, he was exchanged for the French general Victor, and was sent, at the head of a corps, to assist in the defence of Stralsund. After the peace of Tilsit, he was employed at Königsberg and Berlin, and subsequently became commander in Pomerania. When the Prussians at last rose in opposition to France, Blücher was appointed to the chief command in Silesia, and at the battles of Lützen, Bautzen, and Haynau, he displayed heroic courage. At the Katzbach, he defeated Marshal Macdonald, and cleared Silesia of the enemy. In vain did Napoleon himself attempt to stop the 'old captain of hussars,' as he called him, in his victorious career.

In the battle of Leipzig he won great advantage over Marshal Marmont at Möckern, October 16, 1813; and on the 18th, in conjunction with the crown prince of Sweden, he had a great share in the defeat of the French, his troops being the first to enter Leipzig, the next day. In January 1814 he crossed the Rhine, and after winning the battle of La Rothière, pressed forward to Paris; but his scattered corps were routed by Napoleon, and he fought his way back to Chalons with great loss. On the 9th March, however, he defeated Napoleon at Laon; and at the end of the month he again

advanced towards Paris, although sickness compelled him to make the journey in a wagon. The day at Montmartre crowned the brilliant deeds of this campaign, and, on the 31st March, Blücher entered the French capital. Frederick-William III. created him Prince of Wahlstadt, in remembrance of the victory at the Katzbach, and gave him an estate in Silesia. In England, whither he followed the Allied Sovereigns, he received the freedom of the city of London, and the university of Oxford conferred on him the degree of Doctor of Laws. After Napoleon's return in 1815, Blücher once more assumed the general command, and promptly led the army into the Netherlands. On June 16, 1815, he suffered a severe defeat at Ligny, but he personally rallied his scattered troops, and Wellington's victory at the battle of Waterloo was completed by his timely appearance on the field. Blücher despatched his Prussians after the fleeing enemy, and the pursuit lasted all through the night. Declining the offered truce, he marched again against Paris, and on the second taking of that city manifested a strong desire to retaliate on Paris the spoliation that other capitals had suffered; but he was held in check by the Duke of Wellington. In order to reward Blücher's services, Frederick-William III. created a new order, the badge of which consisted of an iron cross surrounded by golden rays. In 1819 a colossal bronze statue was erected in his honour in his native town, and others were afterwards raised in Breslau and Berlin. He died September 12, 1819, after a short illness, at his estate of Kriebowitz, in Silesia. 'Marshal Forwards' was not a great tactician, his victories being due mainly to his dash and energy. In speech and behaviour he was rough and uncultivated; his character was a noble compound of frankness, valour, integrity, and loyalty. His ardent enthusiasm for the liberation of Prussia and Germany from a foreign yoke, and his uncompromising pursuit of this noble aim, have justly rendered him a hero in the eyes of the German people. The statue of Blücher at Breslau is Rauch's masterpiece. The best biographies are those by Förster (Leip. 1821); Scherr (1865); Blasendorff (Berlin, 1877); and the second volume of Wigger's *Geschichte der Familie von Blücher* (Rostock, 1878).

Blue. The blue pigments in common use by artists are few in number, and consist of native and Artificial Ultramarine, Cobalt, Indigo, and Prussian Blue (q.v.). Genuine ultramarine, prepared from the mineral lapis lazuli, and ordinary cobalt blue, sold for artists' work, are permanent colours. They are used either alone, or mixed with other pigments, chiefly for skies and distances in landscape; and by themselves, or to make up grays and other mixed tints in figure-painting. Owing to the exceptionally high price of real ultramarine, the artificial colour, which is of doubtful permanency, is usually substituted for it. Prussian blue and indigo are highly useful colours, since it is only these that yield dark blues, and only from them, mixed with yellows or browns, that strong greens can be obtained. It is unfortunate accordingly that both are more or less fugitive. All the blues above named are used both in oil and water-colour painting, but indigo less than the others in oil, since it is most apt to fade in that medium.

A number of different names are used in commerce for what is essentially the same pigment, or for pigments closely resembling one another. The following statement gives some explanation of these.

Cobalt blues are mixtures of cobalt with earthy or metallic bases, which have been subjected to the action of heat, and have received the following names: Cobalt blue, cerulean blue, royal blue,

Dumont's blue, Saxon blue, Thénard's blue, Leithner's blue, Hungary blue, Zaffre or enamel blue, Vienna blue, azure blue, and Paris blue. The last name is also applied to a Prussian blue, and azure is also given to a variety of ultramarine blue.—*Smalt* is a powdered cobalt glass used in illumination and flower-painting.—*Artificial ultramarine* is also called French ultramarine, French blue, new blue, and permanent blue. Coarse qualities of this colour are largely used by house-painters.—*Intense blue* is a refined indigo.—*Prussian blue* (sesquiferrocyanide of iron) is otherwise named Berlin blue, Paris blue, and ferrocyanide of iron. The name Paris blue is also given to a cobalt colour.—*Antwerp blue* is a variety of Prussian blue made lighter by the addition of an aluminous base, and not so permanent.—*Blue ochre* (hydrated phosphate of iron) is a subdued permanent blue, but not much employed.—*Blue verditer* is a hydrated oxide of copper which changes and ultimately blackens by time. It is used in distemper work and paper-staining.

Blue was worn as a distinctive colour by the Scottish covenants, and is in some places used by Conservatives. The traditional Whig colour was blue also, or blue and buff. *Navy blue* is a dark blue. Dark blue is the Oxford colour, light blue the Cambridge one.

For Blue Dyes, see DYEING; and for blue colours used in the manufacture of GLASS and POTTERY, see these heads. *Blueing* is a name for indigo or any material used for giving a bluish colour to linen. See also TEMPERING.

Bluebeard, the hero of a well-known nursery tale, so named from the colour of his beard. The story is widely known in Western Europe, but the form in which it has become familiar in England is not an independent version, but a free translation of that given by Perrault in his famous *Contes* (1697). In this story Bluebeard is a seigneur of great wealth, who marries the daughter of a neighbour in the country, and a month after the wedding goes from home on a journey, leaving his wife the keys of his castle, but forbidding her to enter one room. She cannot resist her curiosity, opens the door to find the bodies of all Bluebeard's former wives, and at once sees the fate to which she herself is doomed. Bluebeard on his return discovers, from a spot of blood upon the key, which would not be cleaned off, that his wife had broken his command, and tells her that she must die. She begs for a short respite to commend herself to God, sends her sister Anne to the top of the tower to look round if any help is near, and finally is just on the point of having her head cut off, when her two brothers burst in and despatch Bluebeard.

Nothing is more common in folk-tales than stories of forbidden rooms, the entrance into which is at once followed by severe punishment. In the eastern stories, according to Mr Clouston, the room does not usually contain anything very horrifying, unlike most of the western examples of which the story of Bluebeard is a type. A very close parallel to the classical form of the story is offered by a Swabian tale in Grimm's collection; so close, indeed, that in later editions than the first, Grimm omitted it as probably a direct loan from the French. Greek, Tuscan, Icelandic, Esthonian, Gaelic, and Basque versions of the story occur, with varying circumstances of detail, but the main situations identical. Bluebeard is usually a monster or ogre, and lives fittingly in the gloom of forest or cavern—the only really essential detail that has dropped out of the typical story. In one group the monster is the devil, and the forbidden door closes the entrance to hell. In many stories the heroine is the youngest of three or more sisters who have been less lucky, and sometimes, as in one of Camp-

bell's Gaelic variants, she is able to restore them to life. In Campbell's other version, as in the Basque story, it is the heroine herself who cuts off the monster's head.

In the face of such a wide geographical range and self-evident antiquity it is as idle to look for an historical 'Bluebeard' in Gilles de Laval, sire de Rais, who was executed in 1440 for his atrocious cruelties, as it would be to find him in our own Henry VIII., who was so unfortunate with his wives. Literary use has been made of the story by Tieck in his *Phantasus*, and by Gretry in his opera of *Rosalie*. See an excellent study on 'The Forbidden Chamber,' by E. Sidney Hartland, in vol. iii. of *The Folklore Journal* (1885); and Andrew Lang's edition of Perrault's *Contes* (1887).

Blue-bell is the English popular name of the common wild hyacinth (*Scilla nutans*; see *SCILLA*, *HYACINTH*). The 'blue-bells' so familiar alike in the everyday rural associations and in the poetic literature of Scotland are the flowers of *Campanula rotundifolia*, commonly called Harebell in England (see *CAMPANULA*, *HAREBELL*).

Bluebird, **BLUE WARBLER**, **BLUE RED-BREAST**, or **BLUE ROBIN** (*Sylvia* or *Sialia sialis*), an American bird, which, from the confidence and familiarity it displays in approaching the habitations of men, and from its general manners, is much the same sort of favourite with all classes of people in the United States as the redbreast is in Britain. Except in the southern states, it is chiefly known as a summer bird of passage, appearing early, however, as a harbinger of spring, and visiting again 'the box in the garden, or the hole in the old apple-tree, the cradle of some generations of ancestors.'

Bluebird (*Sylvia sialis*).

Their soft agreeable note strikes one of the hours on the living timepiece of the seasons, and has been beautifully called by Burroughs the 'violet of sound.' They are celebrated in American poetry; thus Lowell speaks of

The bluebird, shifting his light load of song
From post to post along the cheerless fence.

Few American farmers fail to provide a box for their nest. In size the bluebird rather exceeds the redbreast, which, however, it much resembles in general appearance. Its food is also similar. The upper parts of the bird are of a rich sky-blue colour, the throat and breast are reddish chestnut, and the belly white. The female is duller in colours than the male. It lays five or six pale-blue eggs, and has two or three broods in the season. The male is remarkably attentive to his mate, and both exhibit extraordinary courage in driving away intruders from the vicinity of their nest. A hen, with her brood, has been seen to flee from the attacks of an

enraged and pugnacious bluebird. The bluebird is known as an inhabitant of the Bermudas, Mexico, the West Indies, Guiana, and Brazil.—In the western and in the more northern parts of North America its place is taken by nearly allied and very similar species.

Blue-books, the name popularly applied to the reports and other papers printed by parliament, because they are usually stitched up in blue paper wrappers. Some departments, however, issue their proceedings in drab, and some in white covers. The practice of printing, and to some extent publishing, the proceedings of the House of Commons, began in the year 1681, when disputes ran high on the question of excluding the Duke of York from the succession to the throne. It was stated that false accounts of the transactions were circulated, and, as a remedy, Sir John Hotham moved that the votes and proceedings of the House be printed. The motion after considerable discussion was carried. The documents printed by the House of Commons accumulated gradually in bulk and variety, until they reached their present extent. In 1836 the House adopted the practice of selling their papers at a cheap rate, and has since that date gradually increased the facilities offered to the public for acquiring parliamentary papers. These are now issued at the following rates: Single paper blue-books, &c., one halfpenny per sheet of four pages, except in particular cases where special prices are charged. For the sum of £20 annually a subscriber may obtain all parliamentary papers published during the year. If the papers relating to the daily votes and proceedings of the two Houses be excepted, a reduction of £3 is made in the cost. The papers of the House of Lords and the House of Commons may be obtained by annual subscription for £10 and £15 respectively. Since August 1886, under the authority of the President of the Board of Trade, a most useful journal has been issued each month (6d.) by that department. It contains in addition to its official notices much valuable information from British, colonial, and foreign sources relating to the trade of the world. In 1898 were issued under the superintendence of Her Majesty's Stationery Office: Papers and Bills of the House of Lords, 326; Bills of the House of Commons, 327; Reports and Papers of the House of Commons, 571; Papers by Command, 674. The chief contents of these papers at present are the votes and proceedings of the House; the bills read in their several stages; the estimates for the public services of each year; the accounts of the expenditure of the moneys voted in the previous year; any correspondence or other documents which the ministry may voluntarily, or at the demand of the House produce, as connected with a question under discussion; reports of committees of inquiry appointed by the House; reports of commissions of inquiry appointed by the crown; and annual reports by the permanent commissions and other departments of the government, stating their proceedings during the year. The blue-books of a session, when collected and bound up, now fill many thick folio volumes. Nothing can seem more hopelessly chaotic than those of a few sessions luddled together unarranged. It deserves to be known, however, that they are all printed according to a peculiar sequence, which enables the whole papers of a session to be bound up in such an order that any paper can be found by consulting an ample index in the last volume. A *précis* of the contents also is now usually given at the beginning of each blue-book. In any library where the blue-books are preserved and properly bound up, the most trifling paper of any session may thus be found with ease; and it need hardly be said that with

much that is useless or unimportant, there is an enormous mass of valuable matter hidden in the blue-books.

An important treasury minute having reference to copyright in government publications was issued August 31, 1887. It stated that while the larger proportion of official publications 'should not, with certain exceptions, be restricted in any form whatever' in their reproduction, a stringent veto would be placed upon the unauthorised publication of charts and ordnance maps, and literary or quasi-literary works—e.g. the Reports of the *Challenger*, the forthcoming state trials, the *Board of Trade Journal*, &c.—The official books of foreign governments corresponding to our blue-books are designated by the colour of their covers. The principal are: France, yellow; Germany and Portugal, white; Italy, green; and Spain, red.

Blue-bottle. See CORN-FLOWER.

Blue-bottle Fly (*Musca vomitoria*), an insect of the same genus with the common House-fly (q.v.). It much exceeds the latter in size, but is smaller than the Blow-fly (q.v.). The head is black, with rust-coloured cheeks, the thorax grayish, the abdomen blue, with a whitish shimmer, and with three black bands. It flies with a loud buzz. The expanse of wings is nearly one inch. It is abundant throughout Britain and Europe generally from spring to autumn, and deposits its eggs on flesh, for which purpose it often enters houses, having a remarkably delicate sense of smelling. The maggots are of very frequent occurrence on meat in summer, notwithstanding all care that can be taken.—*M. erythrocephala* is also called Blue-bottle.—A nearly allied species (*M. casar*), the Green-bottle fly, is distinguished by its golden-green colour, and is also common in Britain, especially on excrement. The maggots develop from the egg in about twenty-four hours; the whole metamorphosis occupies about a month. *M. cornicina* is another common green-bottle. There are many other species. See FLY.

Blue Cardinal. See LOBELIA.

Blue-coat School, a name commonly given to Christ's Hospital in London, and to similar schools in Bristol and elsewhere, the dress of whose scholars is a long dark-blue gown with a belt round the waist, and yellow stockings. Such dress is just that of boys in the first half of the 16th century. See CHRIST'S HOSPITAL.

Blue-eye (*Entomyza cyanotis*), a beautiful little bird, abundant and very generally dispersed in New South Wales, although not found in Victoria. It is one of the Honey-eaters (q.v.) or Honey-suckers, and is sometimes called the Blue-cheeked Honey-eater. It seeks its food almost exclusively among the blossoms and small leafy branches of gum-trees (*Eucalypti*), and finds it partly in insects and partly in nectar, though perhaps also in berries. It is a bold and spirited bird, of most elegant and graceful movements. Numbers are often seen together clinging and hanging in every variety of position, frequently at the extreme ends of the small branches.

Bluefields. See BLEWFIELDS.

Bluefish (*Pomatomus saltatrix* or *Tenmodon saltator*), a fish of the family Scomberidae, of a genus having no detached finlets, no isolated dorsal spines, and no lateral armature of the tail, two dorsal fins, the first of which is small, and two deeply-hidden spines in front of the anal fin. The only known species is abundant on the east coast of North America. It goes southwards in winter, migrates northwards in spring, and is widely spread in tropical and subtropical seas. The upper parts are of a bluish colour, the lower parts whitish, a

large black spot at the base of the pectoral fins. The mouth is crowded with teeth, the jaws are furnished with large ones. The bluefish preys on other fishes, such as the menhaden, and mackerel, the shoals of which it pursues. It is very swift, strong, and voracious. It sometimes attains a length of 3, or even 5 feet, and a weight of 14 lb. It is much esteemed for the table. It is often caught by trolling, as it bites readily at an object drawn swiftly through the water. It frequently ascends rivers even to fresh water.

Blue-gowns, the name commonly given to a class of privileged mendicants in Scotland. The proper designation of these paupers was the King's Bedesmen, or Beadsmen. In ancient times, a beadsman was a person employed to pray for another (see BEAD). From practices of this kind, there sprang up a custom in Scotland of appointing beadsmen with a small royal bounty, who ultimately degenerated into a class of authorised mendicants. Each of the beadsmen on his majesty's birthday received a gown or cloak of blue cloth, with a loaf of bread, a bottle of ale, and a leathern purse containing a penny for every year of the king's life. Every birthday, another beadsman was added to the number, as a penny was added to each man's purse. The most important part of the privilege was a large pewter badge, attached to the breast of the gown, which, besides the name of the bearer, had the inscription, 'Pass and Repass.' This inferred the privilege of begging, and bespoke the kindly consideration of all to whom the beadsman appealed for an alms or a night's lodging. The fictitious character of Edie Ochiltree, in Sir Walter Scott's tale of the *Antiquary*, is a fair sample of this ancient and picturesque fraternity. The practice of appointing beadsmen was discontinued in 1833, at which time there were sixty on the roll. The whole have since died out. The last beadsman drew from the Exchequer in Edinburgh his last allowance in May 1863.

Blue Grass (*Poa pratensis*) is a permanent grass found in Europe and North America. By reason of its creeping root-stocks it forms a dense turf, but is more valued for pasture than for cropping. The blue grass pastures of Kentucky, where it grows spontaneously, have long been celebrated. It is also called June grass. See GRASS, PASTURE.

Blue-jay (*Cyanocitta cristata*), a common North American bird of the Crow family, and occupying in the New World the place held by the jays (*Garrulus*) of the Old. In the United States the blue-jay is sometimes persecuted, sometimes protected, becoming as shy and cunning in the one case, as he is familiar and impudent in the other. They are mischievous birds, but devour large numbers of injurious caterpillars. The length of the bird is almost a foot; the colour is 'grayish purple above, black on the neck, lilac-brown to white below.' The common blue-jay has a wide distribution, and there are several other North American species. The long-tailed blue-jays belong to a rarer genus (*Xanthura*) found in Central and in South America. See JAY.

Blue Light. See BENGAL LIGHT.

Blue Mountains. (1) the name of a branch of the Dividing Range, New South Wales, which run very nearly parallel with the coast, about 80 miles inland. It was not till 1813 that a practicable passage was found over them into the Bathurst Plains. The highest point of the Blue Mountains, Mount Beemarang, is 4100 feet high, and some parts of the road which crosses them are 3400 feet above the sea. A line of railway crosses the Blue Mountains, in the construction of which great engineering difficulties have been overcome. The

Jenolan Caves (q.v.), in the limestone of the Blue Mountains, are remarkable for their great size.—(2) The Blue Mountains, in the centre of Jamaica, attain in the West Peak 7105 feet.

Blue Pill (*Pilula hydrargyri*) is the most simple form in which mercury can be administered internally. It consists merely of two parts of mercury rubbed up with three parts of conserve of roses, till globules of mercury can no longer be detected; to this is added one part of powdered liquorice-root, so that a pill of three grains contains one grain of mercury. In cases of torpid condition of the liver or inflammation of that organ, blue pill is much used as a purgative, either alone or combined with some other drug, such as rhubarb. When it is given with the view of bringing the system under the influence of mercury (Salivation, q.v.), small doses of opium should be added to counteract its purgative tendency, and the state of the gums watched carefully from day to day, so that the first symptoms of salivation may be noticed, and the medicine omitted. As a purgative, the common dose of blue pill is one or two pills of five grains each, followed by a purgative draught. When the system is to be saturated with it, or salivated, one pill may be given morning and evening, or one every night combined with $\frac{1}{4}$ of a grain of opium, repeated till the gums become sore. But the sensibility to the action of mercury varies with the individual; some may take large quantities before it exhibits its physiological effects, and, on the other hand, three blue pills, one taken on each of three successive nights, have brought on a fatal salivation. When taking blue pills, all sudden changes of temperature should be avoided; and, indeed, though they are found in every domestic medicine-chest, neither they nor any other form of mercury should be given without good cause and without the greatest caution.

Blue Ribbon, a term applied to any great prize—as the 'Derby' stakes—from the blue ribbon worn by knights of the Garter.—*Blue Ribbon Army* was the name adopted, from the badge, by the association of total abstinents since 1883 calling themselves simply the Gospel Temperance Union. The organisation was introduced in 1878 from America, where it was known as the 'Murphy Movement' (from its founder), and in three years enrolled in its ranks 3,000,000 of members. It extends over the United Kingdom and the colonies.

Blue Ridge, the most easterly range of the Alleghanies, U.S. It forms the continuation of the chain called South Mountain in Pennsylvania and Maryland. It is known as the Blue Ridge till it crosses the James River; thence till North Carolina as Alleghany Mountain; and in North Carolina again as Blue Ridge.

Blue-stocking, a name given to learned and literary ladies, who display their acquirements in a vain and peilantic manner, to the neglect of womanly duties and graces. The name is derived from a literary coterie formed in London about the year 1750, which included both men and women. A Mr Benjamin Stillingfleet, who was in the habit of wearing blue stockings, was a distinguished member of this society; hence the name, which has been adopted both in Germany and France—*Bes Bleue* being a French translation. See Dr Doran's *A Lady of Last Century* (Mrs Montague), 1872, which contains a chapter on blue-stockings.

Bluetthroat, or **BLUERREAST** (*Cyanocitta stelleri*), a beautiful and melodious bird, nearly allied to the nightingale. From its power of imitating the notes of other birds the Laplanders give it a name which signifies the bird of a hundred tongues. Another of its many names is *Luscinia suecica*, or Swedish Nightingale. It is

very little larger than a redbreast, and much resembles it, but has the throat and upper part of the neck of a brilliant light-blue, with a spot in the centre, which in some specimens is pure white, and in very old males is red. The females have less blue. Below the blue colour is a black bar, then a line of white, and again a broad band of bright chestnut. The bluetthroat is well known as a summer bird of passage in many parts of Europe, from the Mediterranean Sea to the Arctic Ocean, but is very rare in Britain, only a few instances of its occurrence having been recorded. It is supposed to spend the winter in Africa. The bird is one of those known by the names of Beech and Becadico (q.v.), and unfortunately falls victim to epicure tastes.

Blue-wing, a kind of duck, either a sub-genus of *Anas*, or a special genus *Cyanopterus*. The latter title and the popular name refer to the conspicuous colour. The best-known species, the Common or Lunate Blue-wing (*Anas* or *Cyanopterus discors*), is generally called the Blue-winged Teal in the United States of America, where it is very abundant. Vast numbers spend the winter in the extensive marshes near the mouths of the Mississippi, to which they congregate both from the north and from the coast regions of the east; but the summer migrations of the species extend as far north as the 57th parallel, and it is plentiful on the Saskatchewan in the breeding-season. It breeds, however, also in the marshes of the south, even in Texas; and is common in Jamaica, where it is supposed to be not a mere bird of passage, but a permanent resident. In size it is rather larger than the common teal; in the summer plumage of the male, the upper part of the head is black, the other parts of the head are of a deep purplish blue, except a half-moon shaped patch of pure white before each eye; the prevalent colour of the rest of the plumage on the upper parts is brown mixed and glossed with green, except that the wings exhibit various shades of blue, the lesser wing-coverts being of a rich ultramarine blue, with an almost metallic lustre; the lower parts are reddish orange spotted with black; the tail is brown, its feathers short and pointed. The flight is extremely rapid and well sustained. The flocks are sometimes so numerous and so closely crowded together on the muddy marshes near New Orleans, that Audubon mentions having seen 84 killed by the simultaneous discharge of the two barrels of a double-barrelled gun. There are other species of blue-wing, also American; but this alone seems to visit the more northern regions. No member of the duck tribe is in higher esteem for the table, and it has therefore been suggested that the blue-wing is particularly worthy of domestication, of which it seems to be very easily susceptible.

Blum, ROBERT, born in very humble circumstances at Cologne in 1807, was secretary and treasurer of a theatre at Cologne, and subsequently at Leipzig, until 1847, when he established himself as bookseller and publisher. His leisure was devoted to literature and politics, and in 1840 he founded at Leipzig the Schiller Society, which celebrated the poet's anniversary, as a festival in honour of political liberty. When the revolutionary movement broke out in 1848, Blum was one of its most energetic leaders. He was elected one of the vice-presidents of the provisional parliament at Frankfurt, and as such ruled that turbulent assembly by presence of mind and a stentorian voice. In the National Assembly he became leader of the Left, and was one of the bearers of a congratulatory address from the Left to the people of Vienna, when they rose in October. At Vienna he joined the insurgents, was arrested, and was shot

on the 9th November. Blum was a man of strong character, great natural intelligence, and stirring eloquence. The news of his execution excited great indignation among the democrats in Germany, who, besides instituting commemorations for the dead, made an ample subscription for his widow and children. See the Life by his son (Leip. 1878).

Blumenbach. JOHANN FRIEDRICH, a very eminent naturalist, whose influence extended to almost all branches of natural science, was born at Gotha, 11th May 1752. He studied at Jena and Göttingen, and at Göttingen he became extraordinary professor in 1776, and ordinary professor in 1778. Here he lectured for nearly 60 years on natural history, comparative anatomy, physiology, and the history of medicine. In 1785, consequently before Cuvier, he made natural history dependent on comparative anatomy, and zoology in his hands first attained full scientific rank, the real relations of animals being definitely ascertained. His doctor's disputation, *De Generis Humani Varietate Nativa* (1775), raised the great question as to the unity of the human race; his *Institutiones Physiologicæ* (1787), and other treatises, gave a decided impulse to scientific research. His *Manual of Natural History* (1780) went through 12 editions in 50 years. His *Manual of Comparative Anatomy and Physiology* (1804) was translated into almost all the principal languages of Europe. The natural history of man was always a favourite study; and his *Collectio Craniorum Diversarum Gentium*, commenced in 1790, and completed in 1828, gave to the learned world the result of his observations on the skulls of different races, of which he had an extensive collection (see SKULL, ETHNOLOGY). He published other valuable works on natural history, and many essays and papers. Both as a writer and a lecturer he was eminently successful. In 1788 and 1792 he visited England, where he met with a distinguished reception from the most famous naturalists. On the 19th September 1825, his friends and pupils in all countries celebrated the jubilee of his doctorate. In 1835 the increasing infirmities of age compelled him to resign his academical functions. He died on the 22d January 1840. See Marx's *Memoir* (1840), and the work *Göttinger Professoren* (1872).

Blumenthal. JACQUES, pianist, born in Germany in 1829, studied under Herz, and in 1849 came to London. There he received the appointment of pianist to the Queen, taught music, and composed many brilliant, pretty pieces, with songs, of which *My Queen* is the most popular.

Blunderbuss (Dutch *donderbus*, 'thunder-gun'), a kind of short musket with wide bore, capable of firing many balls at once. It is no longer in use, as it had a very limited range, though destructive enough at close quarters.

Blunt. JOHN HENRY, D.D., theologian, born at Chelsea in 1823, was for some years engaged as a manufacturing chemist, but in 1850 entered the university at Durham. He took orders two years later, and held several minor preferments, till in 1873 he received the crown living of Beverstone, Gloucestershire. He died in London, 11th April 1884. Among his numerous works are *The Atonement* (1855), *Household Theology* (1865), *Annotated Book of Common Prayer* (1867), *History of the English Reformation* (1868), *Book of Church Law* (1872), *Dictionary of Doctrinal and Historical Theology* (1870), *Dictionary of Sects* (1874), and *Annotated Bible* (3 vols. 1878-79).

Blunt. JOHN JAMES, divine, born in 1794, at Newcastle-under-Lyme, in Staffordshire, in 1812 entered St John's College, Cambridge, graduated fifteenth wrangler, and obtained a fellowship. Till 1834 a curate in Shropshire, then rector of

Great Oakley, in Essex, in 1839 he became Lady Margaret professor of Divinity at Cambridge, where he died 18th June 1855, having the year before declined the bishopric of Salisbury. The best known of his works is *Undesigned Coincidences* (1833). See Professor Selwyn's memoir of him prefixed to his *Two Introductory Lectures* (1856).

Blunt. WILFRID SCAWEN, traveller and poet, was born near Crawley in 1840. His mother being a Catholic convert, he was educated at Stoneyhurst and St Mary's, Oscott. He served for some years as attaché to various British embassies in Europe; married in 1869 Anne, daughter of the Earl of Lovelace, and granddaughter of Lord Byron; and thereafter travelled through Spain, Algeria, Egypt, and the Syrian desert, as recorded in Lady Anne Blunt's *Bedouins of the Euphrates*. In 1882 he championed the cause of Arabi Pasha in Egypt. The same sympathy with national aspirations afterwards plunged him into the Nationalist cause in Ireland, and led to his being imprisoned for two months in 1887-88 for taking part in a prohibited meeting in County Galway. Blunt is the author of several volumes of verse, *Sonnets and Songs*, the *Love Sonnets of Proteus* (the last containing poetry of really striking merit), *Esther, Love Lyrics, The Wind and the Whirlwind* (on Egyptian affairs), *In Vinculis, Satan Absolved* (1899), &c. A selection of his poetry was edited in 1898 by Henley and Wyndham.

Bluntschli. JOHANN KASPAR, jurist, was born 7th March 1808, at Zurich, where in 1833 he became professor in the new university. In politics he at first inclined to reform, but after 1839 was Conservative leader. He was a councillor of state, and became a member of the government and of the federal directory, and afterwards worked for the formation of a moderate Liberal-Conservative party in Switzerland. In 1848 he went to Munich as professor of Civil and International Law. There he published his *Allgemeines Staatsrecht* (5th ed. 1876), on which his reputation as a juriconsult chiefly rests; *Deutsches Privatrecht* (3d ed. 1864); and, in conjunction with Arndts and Pözl, *Kritische Ueberschau der Deutschen Gesetzgebung und Rechtswissenschaft* (6 vols. 1853-58). In 1861 he removed to Heidelberg University, and became a privy-councillor of Baden, actively forwarding all liberal measures in the state. Liberty in ecclesiastical matters he had equally at heart; he acted several times as president of the *Protestantenverein*, and it was after delivering a closing speech at the general synod of Baden that he died suddenly at Karlsruhe, 21st October 1881. He is the author of valuable histories of Zurich and of the Swiss Confederation, and of a number of works on law, being especially an authority in international law. In 1884 his autobiography appeared in three volumes.

Blushing is a sudden reddening of the skin, induced by various mental states, particularly those involving shame or humiliation, shyness or modesty. It usually affects only the face and neck; rarely among civilised peoples the breast and other parts of the body. But 'the men of certain races, who habitually go nearly naked, often blush over their arms and chests, and even down to their waists' (Darwin). It is often accompanied by expressive movements; the face is turned aside, the eyes cast down or restlessly moved. It causes increased heat of the parts affected, with a sensation of heat and tingling, and often a general feeling of discomfort. It does not occur in young children.

Blushing is an excellent illustration of the control exercised over the circulation of the blood by the nervous system. Under ordinary circumstances, the muscular coat of the small arteries throughout

the body is constantly maintained in a state of partial contraction by means of the nerves distributed to it (*vasomotor* nerves; see NERVOUS SYSTEM). The blood propelled into them by the heart is thus prevented from distending them to their full extent, and its passage to the capillaries in connection with them is controlled. When, however, from any cause the action of these nerves is suspended, the arteries under their influence at once dilate, the corresponding capillaries become fuller, and the tissues containing them appear much redder than in their ordinary condition.

Under the influence of shyness, shame, &c. an alteration takes place in the nervous influence proceeding from the brain, which, for the time, lessens or stops the action of the nerves controlling the arteries of the skin of the face and neck, and blushing is the consequence. Why it should result from these and not from other mental states, and why the effect should be confined in general to the face and neck, are much more intricate questions, which cannot be discussed here. For one answer to them, with many interesting facts on the subject, see Darwin, *Expression of the Emotions*, chap. xiii.

Boa, a term popularly applied to the large snakes of the Python and Boa Constrictor families. The former are Old-World, the latter New-World giants, and closely resemble one another both in structure and habit. Both are very large, not poisonous, with great powers of crushing, with an expansible gape, with prehensile tails, with rudimentary traces of the hind-legs beside the anus, and so on. Apart from general difference of habitat, the two families may be distinguished by the facts that in the pythons the premaxillæ (most anterior upper jaw-bones) bear teeth, but not in the boas; that the inferior shields of the tail are in two rows in the former, in one in the latter. Leaving the python family meanwhile, we may resume the characters of Boideæ in the strict sense.

Head of Boa.

The body of these large non-venomous crushing snakes is slightly compressed sideways, and is covered with smooth or keeled scales. The gape, tail, and hind-legs are referred to above. The genus *Boa* itself has smooth scales, a scaly head, lateral nostrils, and characteristic arrangement of shields. The common species (*Boa constrictor*), found in the north and east of South America, is usually about 12, but, according to report, may be over 20 feet in length. The colour of the back is reddish gray, with zigzag, broad, dark longitudinal stripes, including oval grayish-yellow spots; the head exhibits three dark stripes. It frequents dry bushy regions, is shy of man, and

little feared. To a large extent arboreal in its habits, it is aided in climbing by the rudimentary claw-like hind-limbs. From its concealment the boa swoops down on even comparatively large mammals, crushes them in its coils, and swallows them slowly. The bones are broken by the external crushing, a copious flow of saliva within the mouth makes the laborious swallowing of the large mass somewhat easier, but it is at the best a tedious and exhausting process. After a meal comes a period of digestion and quiescence, and in this state of torpid lethargy they may be readily killed. On waking up they are very hungry, and the demands of appetite at this time prompted a boa in the Zoo to swallow its rug, which, after a week or two of unsuccessful digestion, it put up again. The boa bears its young alive. The skin of the *Boa constrictor* is used for making boots, saddle-covers, &c. The great water-snake Anaconda (*Eunectes murinus*), the Xiphosoma of the Amazon district, which occasionally visits houses; the Enygrus of Java, Amboyna, and New Guinea, with keeled scales, are closely allied genera of Boideæ. See ANACONDA, PYTHON, SNAKES.

Boabdil (properly Abu-Abdallah, and nicknamed Ez-Zogibiy, 'the unlucky'), the last Moorish king of Granada, dethroned his father, Abu-l-Hasan, in 1481, and two years later was defeated and taken prisoner by the Castilians near Lucena. He was set free on condition of paying tribute, and returned to Granada to struggle with his father and with his heroic uncle, Ez-Zaghal, for the throne. Thus the Moors wasted the strength they sorely needed for the final struggle with the Christians. The fall of Malaga and Baza was but the prelude to the siege of the capital itself, which was finally starved out towards the close of 1491, spite of the reckless courage of the Moors and of Boabdil, whose weak and vacillating nature fell from him in the hour of battle. The unhappy king gave up to Ferdinand the keys of the city, then turned his back on Granada, and rode on towards the mountains. At Padul, on a spur of the Alpujarras, he turned to take a last look at the towers of the fair palace and city he had lost. 'Allahu Akbar' ('God is great'), he exclaimed, as he burst into tears. His mother stood beside him. 'You may well weep like a woman,' she said, 'for what you could not defend like a man.' The spot from which Boabdil looked his last on Granada still bears the name of *el ultimo suspiro del Moro*, 'the last sigh of the Moor.' He soon crossed to Africa and flung away his life in battle.

Boadice'a, 'the British warrior-queen,' wife of Prasutagus, king of the Iceni, a tribe in the time of the Romans inhabiting the part of Britain now occupied by the counties of Norfolk and Suffolk. On the death of her husband about the year 60 A.D., the Romans seized her territory, and treated the inhabitants with the most brutal cruelty. The queen herself was scourged, her daughters were outraged, and the noblest among the Iceni were treated as slaves. Boadicea, roused to fury by her wrongs, gathered round her a large army, destroyed the Roman colony of Camulodunum (Colchester), took Londinium and Verulamium (London and St Albans), and put to death, according to Tacitus, as many as 70,000 Romans. Suetonius Paulinus, the Roman governor of Britain, who had been absent in Mona (Anglesey), now advanced against the queen, and with not more than 10,000 men inflicted an overwhelming defeat on an enemy twenty times as numerous. The British loss is said to have been 80,000, the Roman only 400. Boadicea, overwhelmed with despair, killed herself by poison. Her story is best remembered by the noble poems of Cowper and Tennyson.

Boar. WILD (*Sus scrofa*), a non-ruminant, even-toed hoofed mammal, with conical teeth (Ungulata, Artiodactyla, Bunodontia). The family (Suidae) to which the boar belongs, and which also includes the river-hog, the babiroussa, the wart-hog, the peccari, &c., is characterised by the pointed head with familiar pig-snout, large ears and small eyes; by the thin legs, often curled tail, bristly hide; by the four toes on fore and hind feet, of which only the two inner reach the ground; by the prominent canines, especially in the males. They are also notorious for their voracious omnivorous diet, love for damp places, and rapid multiplication.

The wild boar is a large powerful beast, measuring 4 feet or more in length, with very strong and formidable canine teeth in the male. The head is more elongated than that of the domesticated form. The strong bristles are blackish-brown, mingled with yellow, and these, along with the brownish-gray under-hair, give the animal a dark grayish-brown colour, often approaching black.

Wild Boar.

The young ones are yellowish for six months, and have white and brown stripes or spots. The adult males usually live alone, but the female is accompanied by her family, and sometimes by other sows and families. Four to six young are born in a litter. The boars come from their places of concealment at night; they devour all sorts of things, but especially vegetable produce. The sense of smell is acute, and they do not miss much of what they root up. By their voracity and ruthless grubbing they do great damage to crops and to young trees. On account of this, as well as for the sake of their flesh and bristles (q.v.), they are much hunted in the regions where they occur, and the fury of the enraged male, and the zeal of the sow in protecting its young, add a spice of danger to the chase. In some parts of India 'pig-sticking' is the chief sport. Many species of *Sus* have been distinguished, but four or five alone are certain: *S. vittatus*, 'from Sardinia to New Guinea, from Japan to Damaraland (South-west Africa); *S. verrucosus*, from Java and Celebes; *S. barbatus*, from Borneo; and *S. scrofa*, formerly common throughout temperate Europe and Asia. At Chartley, in Staffordshire, the wild boar was not extinct so late as 1683; and at Sydnop, in Derbyshire, Alpine boars and sows, introduced from the Continent, bred between 1823 and 1837, when the last was shot (Harting's *Extinct British Animals*, 1880). The wild boar is still common in woody damp regions in some parts of the Continent.—Fossil species occur in the Miocene and Pliocene strata. Hyotherium is abundant in the upper Eocene and Miocene ages. The oldest representatives are Eohyus and Achaenodon (Parahyus?) from the lower and middle Eocene, the former 'with at

least four functional toes, and with certain peculiar carnivore modifications of the skull.' Heilprin calls attention in this connection to the remarkable Pachysmia, found in the phosphorite deposits of Quercy, France, which are held by Filhol 'to possess striking structural features allying them with the Primates.' It would be indeed curious if the monkeys should find their ancestors among such beasts.

A boar's head, served up as the most important dish on the baronial table, was the subject of many a carol and poetical allusion connected with Christmas festivities in England. The boar's head (see HERALDRY) is a well-known cognisance. For the wild boar's tooth, see also BABIROUSSA; for swine in domestication, see PIG.

In hunting the boar, any and every large and powerful kind of dog has been used, those with rough coats being preferred, as being less liable to severe injury from the boar's tusks. But the name BOARHOUND is generally given in England to the breed also known as Great Dane, Ulmer Dog, Deutscher Dogge or German Mastiff. It is a strong, handsome dog, which may reach thirty-three inches in height at the shoulder, carrying the head and neck high, with prick ears. It unites the strength of the mastiff with the elegance of the greyhound. It hunts chiefly by sight, but is usually a kindly, companionable dog, and is in Britain rarely employed in the chase. The hair is short, hard, and dense, the colour various shades of gray ('blue'), red, black, or white, with patches of the other colours.

Boarding is the name for an attack by one vessel on another, a company of armed men from the one forcing their way on board the other. In the days of ironclads, boarding of war vessels is less frequent than of old. See TACTICS (NAVAL). A *boarding-net* is a framework of stout rope-netting placed so as to obstruct boarders.

Boarding-out System. See POOR.

Boardman, GEORGE DANA, Burmese missionary, was born in the State of Maine in 1801, and educated at Andover. Ordained in the Baptist Church in 1825, he sailed the same year to the East Indies, and after mastering Burmese, began his labours at Maulmain in May 1827. He had great success, especially in his preaching tours; but the severe strain soon broke down his health, and brought on his death early in 1831. His widow married the more famous Burmese missionary, Judson.

Board of Trade. See TRADE. For other boards, see WORKS (BOARD OF), EDUCATION, LOCAL GOVERNMENT, POOR, &c.

Boar-fish (*Cupros*), a genus of fishes in the

Boar-fish (*Capros aper*).

Carangidae or Horse-mackerel family of Acanthopterygii or bony fishes with spinous rays. The

protrusible mouth presents a resemblance to a hog's snout as the name suggests. The body has an oval compressed form like that of the related John Dory, from which it differs conspicuously in the absence of spines at the base of dorsal and anal fins, and of long filaments on the dorsal spines. The common Boar-fish (*C. aper*) is a well-known inhabitant of the Mediterranean, rarely caught on the coasts of England. The eyes are very large, and placed far forward; the body is of a carmine colour, lighter below, and with seven transverse orange bands on the back.

Boarhound. See BOAR.

Boat is the general name for a small open vessel. Boats differ, however, greatly from one another. They may be slight or strong, sharp or flat bottomed, swift for despatch or roomy for cargo, ornamental for pleasure or plain for hard service, deep or light of draught for deep or shallow water. The royal navy formerly set the pattern for the large merchant-ships; but the introduction of steam-launches of all sizes has practically brought about the extinction of the largest kind of boats propelled by oars for the use of ships of war. The length of the steam-launches is usually 38 to 42 feet, and they weigh (without boiler) from 90 to 113 cwt. A steam-pinnace, 30 to 37 feet, weighs (without boiler) 52 to 83 cwt.; and a steam-cutter, 21 to 28 feet, weighs (also without boiler) from 13 to 33 cwt. A steam-launch will carry 70 men; a pinnace, 50; a cutter, 20. The boats kept for rowing are: *Barge*, a long, narrow, light boat, employed in carrying the principal officers to and from the ship. An 'admiral's barge' is 34 feet long, and weighs 23 cwt. (For other kinds of boats or vessels under this name, see *BARGE*.) A *Pinnace*, a boat for the accommodation of the inferior officers, ranging from 25 feet to 35 feet in length, has usually eight oars, whereas the barge has ten or more; a *Cutter*, broader and deeper than the barge or pinnace, ranging from 20 feet to 32 feet, and weighing from 10 to 20 cwt., is rowed with six oars, sometimes hoists a sail, and is chiefly employed in carrying light stores, provisions, and crew; a *Jolly-boat* is a smaller cutter, rowed with four oars instead of six; whilst a *Yawl* is small in size, and used for nearly the same purposes as cutters and jolly-boats. A *Gig* is a narrow boat, ranging from 22 to 32 feet, and weighing from 6 to 9 cwt.; it is rowed with six or eight oars, and employed by the chief officer on expeditions requiring speed. Some of the above-named boats are diagonal-built for strength; the others are clencher-built, to be as light as possible. Besides the foregoing, *life-boats*, ranging in length from 23 to 28 feet, and in weight from 8 to 11 cwt., are carried; also a *dinghy* of 12 or 14 feet, and weighing about 3 cwt. The latter are capable of being rowed by one or two men. A merchantman ordinarily carries a pinnace of from 25 to 30 feet; a life-boat, 20 to 30 feet; and a jolly-boat, 14 to 24 feet. Passenger-ships are, however, required by law to carry a sufficient number of boats to hold the whole number on board; but often this is not done.

In reference to the legal regulation of boats in the merchant-service, the following are the chief provisions: When a boat belongs to any ship or other vessel, the name of the vessel and of the place to which she belongs must be painted on the outside of the stern of the boat, and the master's name within-side the transom—the letters to be white or yellow on a black ground. Boats not belonging to ships or other vessels must be inscribed with the name of the owners and the port to which they belong. All boats having double sides or bottoms, or any secret places adapted for the concealment of goods, are liable to forfeiture.

The boats intended for the rescue of shipwrecked persons, or crews and passengers exposed to that danger, are described under *LIFEBOAT*.

Yachts' boats vary in size according to the dimensions of the yacht. A cutter for an 80-ton yacht would be about 17 feet long, and be rowed by four oars; whilst a yacht of 300 tons would have one 34 feet long, and capable of being propelled by six or eight oars. A yacht's cutter is of good depth and breadth, and employed by the crew in watering or other services, or by the owner in rough weather; the length is generally four times the breadth, and the depth one-tenth the length. A yacht's gig varies in length from 18 to 32 feet, and is rowed by four, six, or eight oars. The length is about 4·8 times the breadth, and the depth one-twelfth the length. A yacht's dinghy ranges from 8 feet to 14 feet in length, the breadth being one-third the length, and the depth one-seventh.

Boats differ very considerably at various parts of the coast, and are generally adapted to the nature of the beach and general condition of water they are employed in. Thus on the Thames, the waterman's skiff or wherry (fig. 1) is usually of

Fig. 1.—Thames Wherry.

very light build, whilst on the coast they are comparatively heavy, to bear the straining they are subject to in rough water and constantly beaching. On the south coast the square-sterned skiff is mostly in use, and is generally about 14 feet long, with three thwarts (or transverse seats), and the seat in the stern, with two side-seats. These boats are met with about the watering-places from the Thames to Weymouth, and are usually in charge of one man. At Portsmouth the waterman's boat is sharp-sterned like a whale-boat, and is usually termed a wherry. They are generally fitted with a sprit mainsail, a mizzen, and a foresail. These boats vary in length from 16 feet to 25 feet, and are admirably adapted for going through the broken water between the harbour and Spithead, the sea being very short and steep with an east wind on an ebb. Indeed, these boats often keep up communication with the fleet at Spithead when the ships' boats are not allowed to leave. On the north-east coast a peculiar flat-floored boat is in use, and termed a coble (fig. 2). They are of shallow draught, and when being sailed, the peculiarly deep rudder helps to check their tendency to make leeway when close-hauled.

Fig. 2.—Coble.

On the Irish coast, the boats generally are of a very primitive form and construction. The Wexford cot is quite flat-bottomed, with two outside keels (see sketch); whilst on the west coast the boats are 'round' everywhere—round in the bottom, round in the bow, and round in the stern. There are many other varieties of boats around our shores, but those mentioned are the most distinct in type.

Fig. 3.—Wexford Cot.

Of the many boats used for pleasure, none are

more popular than the Thames Randan skiff (fig. 4), ranging in length from 20 to 40 feet. They are

upper ends by a fore-and-aft batten of wood. The stem and stern-post are held in position on the

Fig. 4.—Randan Skiff.

Fig. 5.—Four-oared Racing-boat.

usually built of cedar or mahogany, and beautifully finished and fitted like a state barge.

Competition among oarsmen has brought into existence the racing-boat with outrigger rowlocks. These boats are usually built of cedar for lightness, canvas-covered, and so light in construction that a sculling-boat (termed a wager-boat) 30 feet long weighs no more than 30 lb. They are only of sufficient width to seat the sculler, and require expert handling to prevent an upset. The ends of the boats are decked over with oiled or painted canvas.

The dimensions and weights of racing-boats are as follows :

Description.	Length over all.	Extreme breadth.	Depth amid- ships.	Weight, including outriggers, but not oars.
	ft.	in.	in.	lb.
8 oars	59	23	9	240
6 oars	50	23	9	200
4 oars	42	20	8	140
2 oars	36	15	7	45
Sculling ..	31	10 to 12	5½	31

On the Thames, the London Rowing Club has twelve-oared racing-boats of about 75 feet long. See CANOE, CATAMARAN, PROA, &c.; for boat-racing, see ROWING; and for sailing-boats, see SAIL, YACHT.

Boat-building.—Boats are usually built by eye, but occasionally their shape is delineated on paper

by a series of curved lines. In the latter case these lines are transferred to the floor of what is termed a 'mould loft,' and the drawing made of full size—i.e. of the size that the

Fig. 6.

boat is actually to be. From this drawing moulds of the cross sections are made, as shown by fig. 6; *a* is a notch to fit over the keel. The stem, stern-post, and keel are then cut out of the required shape, and tenoned together. They are then fixed on building stocks consisting of blocks

Fig. 7.

of wood, or of what is known as a 'deal' secured edgeways in a horizontal position on uprights (see fig. 7).

The stem and stern-post, besides being tenoned to the keel, are further temporarily connected at their

upper ends by a fore-and-aft batten of wood. The stocks by struts extending to floor and beams in the roof of the shop. The transom (see fig. 8) and moulds of the cross sections are then fixed into their proper places, and secured to the fore-and-aft batten and to the roof by struts. The moulds are then further secured by ribbons or bands of wood temporarily bent round their outside edges. These edges and the stem

and stern-post are then marked (see *b, b, b*, fig. 6) to represent the width of the plank, the latter usually being about 5 inches wide, with about ¼ inch overlap, termed the land in clencher-built boats (sometimes termed clincher or clinker). The bottom plank, known as the

Fig. 8.

A, transom; B, stern-post; C, keel.

garboard strake, is first fitted into the rabbet or groove cut in the keel, stem, and stern-post to receive it, and nailed at intervals of about 3 inches. A plank is then taken and held over the upper edge of the garboard, and marked round with chalk or pencil. The plank is then removed and sawn through by the chalk line, care being taken to provide for the overlap. The plank is then further cut to the right width to fit the marks on the moulds, *b, b*, stem and stern-post, and then planed and edges bevelled as required to fit round the curve of the moulds. The plank is held in position by a series of wooden clamps, set up by wedges, as shown in fig. 9. The edges of the plank are then nailed together at intervals of 3 inches, the nails being clenched on the inside on rooves (small copper rings). When all the plank is on, the timbers or ribs are put in; these are usually made of American elm on account of its straight grain, flexibility, and toughness.

Fig. 9.

The ribs having been cut to the required size, are put into a steam kiln (which is a long box supplied with steam from a boiler) until they are sufficiently pliant to be easily bent round the bilge of the boat inside. The timber is now nailed (from the outside) to the plank, each nail being clenched on a roove. After the timbers have been fitted and nailed, the 'in-wale' (a batten of wood inside the gunwale) is fitted over their heads, and nailed and rooved to the gunwale strake. A bearer or stringer is then fitted round the boat inside, to take the seats or thwarts, the latter being further secured to the sides of the boat by oak-knees. In the case of boat-building without moulds, the garboard strake is fitted as already described, and also the next strake. Each succeeding strake is fitted in the same manner, the boat-builder giving such a curve to the bilge and sharpness to the bow or stern as his judgment and experience may direct; and often

a 'rule-of-thumb builder' turns out a handsomer boat and better model than the man who works by lines. Fig. 10, A, shows in detail the construction of a clencher-built boat; *s* is an oak-knee

Fig. 10.

floor fitted to the sides of the timbers when the bottom of the boat is so sharp that the timbers cannot be bent round over the keel.

In a carvel-built boat the edges of the plank meet as shown by fig. 10, B. The seams are caulked with oakum or cotton, and payed with pitch or marine glue. Racing-boats and canoes are usually carvel-built, but the plank is too thin to admit of caulking, and a strip of canvas or wood is worked over the seams inside. When a strip of wood is used, the work is termed ribbon carvel (fig. 10, C).

Boatbill (*Canceroma cochlearia*), a bird of the Heron (q.v.) family, the only known species of a genus differing from the true herons in little else

Boatbill (*Canceroma cochlearia*).

than the form of the brown bill, which is comparatively short and very broad, the mandibles resembling the bowls of two spoons placed one upon the other, the upper mandible overlapping the lower, keeled on its upper ridge, and hooked at the point. The boatbill is about the size of a domestic fowl, has shorter limbs than most of the herons, but resembles them in plumage, and is abundantly provided on the back of the head and neck with elongated feathers, which it erects when irritated. The front parts are white (the crown black in the male), the upper surface and tail whitish gray, the under side yellowish white, the belly rusty red. It inhabits Cayenne, Surinam, Brazil, &c., sits perched upon trees which hang over streams, and darts down upon fish, which seem to be its principal food.

Boat-fly (*Notonecta*), a genus of insects of the order Hemiptera (q.v.), sub-order Heteroptera, and family Hydrocores, or Water-bugs (q.v.).

The English name well describes their boat-like form, eminently adapted for progression in water. They have the peculiar habit of always swimming on their back, and of resting in this posture suspended at the surface of the water. Their hindmost legs are very long, and when these are thrown out at rest the insect looks like 'a waterman resting on his scull.' One species, *N. glauca* (sometimes called the *Water Boatman*), is common

Water Boatman (*Notonecta glauca*).

in Britain and throughout Europe; it is about half an inch long, and varies considerably in colour; but exhibits a general greenish tinge, the other colours being black, brown, and gray. They fly well, but seldom use their wings. They move with difficulty on dry ground, and prefer to keep to quiet water. When they descend into the water, they carry down a supply of air in a hollow between their folded wings. They feed voraciously on animal substances, often kill and devour those of their own species, and are said to do damage among fish-spawn. There are many species, but only two are European. An allied genus (*Corixa*) swims in the normal fashion, and is represented in almost every quiet pool.

Boat-lowering and Disengaging Gear, an inclusive term for the system of ropes, blocks, and davits or cranes, by which ships' small boats (see **BOAT**) are lowered to the sea, and sent clear of the fastenings. For a long time in the early history of shipping, no proper means were employed for launching boats, but afterwards, and especially as the passenger-carrying trade developed, vessels were built having davits with blocks and falls, or tackle. At first the davits were fixed wooden uprights at the side of the ship; then wooden uprights, moving upon hinges or pivots called 'topping davits'; then of curved iron, fixed in sockets, but capable of turning round. The last-named method is still the one most universally adopted, although a plan of working a curved iron davit upon a hinge or pivot, in a similar manner to the old wooden topping davit, has been sometimes fitted within recent years. Until within comparatively recent times, the almost universal mode of attaching boats to the falls and blocks was by a fixed hook on the bottom of the lower block, which hooked into an eye or ring fixed near the bow and stern of the boat. The many calamities befalling boats thus fitted when being launched in the hurry and excitement of shipwreck or other emergency at sea, led to the invention of more efficient and reliable means for safely disengaging them from the lowering tackle, and for regulating the process of lowering as well. The first recorded invention of an improvement in lowering and disengaging boats is that of Lieutenant Cook, R.N., in 1830. The next invention was by Shore in 1836; and in 1852 Stirling, Lacon, and Dewey each invented a system of disengaging boats. From that time till now, the records of the Patent Office show a continuous and plentiful list of devices, many of them, however, simply being modified forms of methods formerly patented. A goodly proportion

have related only to the mode of housing and *lowering* boats; but in the case of Clifford's apparatus, which, more than any other, at one time met with wide acceptance, the work of *disengaging* was also embraced. The aim in this apparatus, which began to be introduced in 1836, was the rapid and equable lowering of boats, by unreeving pennants placed round drums and rollers, and the simultaneous disengaging of both hooks; the whole operation being under the control of one man seated in the boat. When first brought out, and when fitted and worked properly, this plan was a most successful one, and without doubt its adoption led to the saving of many lives. As time went on, however, it was found that the pennants were allowed to get out of order, and being often made of inferior material, were unreliable, while in frosty weather they became almost useless. The necessity also of using the old blocks and falls to hoist the boat was too often the cause of the apparatus not being immediately and properly adjusted for lowering, and in consequence found worthless at the moment of necessity. Its adoption therefore did not extend, and at the present time, although other and better apparatus have been designed to accomplish the safe lowering of boats, the almost universal practice, as before stated, is to employ the old and primitive plan of simple blocks and falls.

With regard to *disengaging* boats (perhaps the most critical part of the whole operation of launching), the number of patented gears is very large. Captain Kynaston, R.N., in 1857 invented and patented a slip-hook which for several years received the approval of the Admiralty, and was fitted in the boats of many naval ships. An improved form of the same hook was designed by Mark Robinson. In 1870 Hill & Clark patented a novel hook—improved subsequently—which has been extensively adopted both in the naval and mercantile marine; and in 1872 a disengaging apparatus, similar in principle to previous gears, was patented by Douglass, and received for several years extensive adoption in merchant-ships. This consisted of a round ball attached to the end of the falls, and a cup or socket fitted in the seats at each end of the boat, the balls fitting into the sockets, and being held there by means of levers, the tops of which pressed partly over the balls, and gripped them. These levers were kept in position by means of a tightened chain held by a trigger in the centre; when this trigger was released, the chain slackened, and allowed the levers to open, and the balls to clear. This plan, like some of the other methods, had the disadvantage (a most serious one in cases of dire emergency or panic) of permitting the boat to be detached when suspended at any height; the disengaging thus being entirely dependent upon the judgment of whoever had charge of the trigger. Recent and more approved methods insure that a boat suspended from the falls cannot be unhooked or released until entirely water-borne, and all strains taken off the falls.

It would occupy too much space even to simply enumerate recently patented gears; it must suffice to illustrate and describe one of the simplest. Figs. 1, 2, and 3 illustrate a disengaging apparatus designed and patented by W. F. Rees, R.N., curator of the Naval Museum, Greenwich. Fig. 1 shows the disengaging hooks in position, with the boat under suspension. Fig. 2 shows an enlarged view of the hook as it appears with the boat suspended. It will be seen that it consists of a straight shank with, at its upper end, the hook proper, pivoted through its crown, and at its lower end the slot and pin-hole, wherewith to fix it to the standard or sling reaching down to the keel of the boat. Half-way up the shank, and pivoted to it, is a slotted tumbler which receives

and holds the bill or point of the hook when the boat is suspended. When, however, the fore and aft line, reaching from tumbler to tumbler and

Fig. 1.

holding them up, is allowed to slack, the tumblers drop and allow the hooks to swing back on their pivot (see fig. 3), thus freeing the block and tackle. The fore and aft line is thus the key to the whole operation of disengaging. It is attached to the after-tumbler; the end, after passing through the

Fig. 2.

Fig. 3.

forward-tumbler, is belayed round the cleat or after-thwart, and is under control of the coxswain. By keeping the line hand-taut while the boat is being lowered, there is no possibility of the boat disengaging itself should one end of it touch the water before the other. Indeed, even when the boat is completely water-borne, the hooks of themselves cannot become disengaged, unless as the result of an intentional slackening of the line. The small safety-pin with chain shown on fig. 2 is used to keep the hook in position when there is no strain on the fall—i.e. the boat not under suspension—and the fore and aft line is not taut; for example, when attaching the falls, previous to hoisting up the boat. In rough weather or in the dark, the boat can be hoisted up by simply slipping the eye of the lower block over the second small fixed hook, shown at the back of the shank, the disengaging hooks being afterwards adjusted ready for lowering again.

Boat-plug, a wood, cork, or metal stopper, fitted through the bottom of ships' boats, wherewith to drain them of the water which may have been shipped or have leaked in while the boats were in use, or of rain-water. The Board of Trade require that each boat shall have two plugs—one a spare one—both to be attached to a fixed part of the bottom by lanyard or chain. To prevent accidents from the omission to restore the plugs, *self-acting* plugs have from time to time been

devised, but have never been very extensively adopted. One of these inventions consists of a metal valve and fittings secured into the bottom of the boat, the valve being formed of a hollow truncated cone, which remains close against the valve seat by the pressure of the sea as long as the boat is water-borne; but immediately the boat, or that portion of it containing the plug, is out of the water, the valve falls by its own weight, and drains the boat effectively.

Boat-racing. See ROWING.

Boatswain is an officer on board ship, who has charge of the boats, sails, rigging, cables, anchors, flags, and cordage. In the navy he is a warrant-officer, and is immediately under the navigating officer in some of these duties; he frequently examines the masts and yards, sails and ropes, to report on their condition and efficiency. He also keeps account of all the spare rigging, &c., and superintends the replacement of old by new. He assists in the necessary business of the ship, and in relieving the watch. The *boatswain's mate* assists in all these duties. See WARRANT-OFFICERS.

Bobadil, a braggadocio, from a blustering captain in Ben Jonson's *Every Man in his Humour* (1598).

Bobbin-net, or BOBBINET, machine-made cotton net, an imitation of bobbin-lace. See LACE.

Bobbins are small wooden reels or rollers, flanged at the ends, and bored through the centre lengthwise, so that they can be placed on a spindle or skewer. The bobbin or pirn on which ordinary sewing-thread is wound, although generally of small size, is a good example of their prevailing shape. Bobbins are used in the spinning processes for cotton, flax, wool, and silk, and are of various sizes, the largest being generally those used for the slubbing frames where the cotton, for example, first passes from the lap shape given by the carder into a loose kind of strand. After this the bobbins diminish in size for the various succeeding stages to the finished yarn. A 'slubbing' bobbin may be 15 inches long and 5 inches in diameter at the flange, but one or two exceptional kinds are larger than this. For special purposes, such as lace-making, the bobbins used are quite unlike the ordinary kinds. These and some other varieties are made of metal. Paper tubes are now largely adopted in certain cases where bobbins were formerly employed. Bobbins are made of birch, beech, ash, and plane tree, and machinery for their manufacture has been erected here and there in the Highlands of Scotland and other wooded parts of the country. But they are also largely made of American and other foreign woods, as well as from native material, in factories in Lancashire and Yorkshire. Ingenious automatic machinery is now employed, especially for making the smaller sizes. It will be readily understood that bobbins are used in enormous numbers wherever there are large spinning-mills.

Bobbio, a Lombard town, 3 miles SSE. of Pavia, near the confluence of the Bobbio and the Trebbia. Bobbio originated from a monastery founded here in 612 by St Columbanus (q.v.), whose famous library has mostly found its way to the Vatican. Since 1014 it has been the seat of a bishopric. Pop. 4635.

Bob-o-link, or BORLINK, REED BIRD, or RICE BIRD (*Dolichonyx oryzivorus* or *Icterus arizonensis*), a common American bird found from Paraguay to Canada, the only one of its kind, and that difficult to classify. Some place it near the Baltimore bird (*Icterus*), others near starlings, but both the characteristics and the character of the bob-o-link exhibit much that is unique. The beak is short

and straight; the nostrils surrounded by a fold of skin; the wings are long, especially in their first feather; the tail-feathers are still-pointed. The

Bob-o-link.

plumage is unusually conspicuous for a ground bird. In the male the head, lower surface, and tail are black, while the upper surface is lighter, yellowish white in front, black with yellow streaks behind. The colour and the note change with the seasons and with the functions of the bird. The female is much plainer—yellowish brown with darker streaks above, and pale grayish yellow below.

The name—originally *Bob Lincoln*—is an imitation of the bird's note. In song, the full-throated male bob-o-link is unique, rivalling the lark, imitable by the mocking-bird, 'in qualities of hilarity and musical tintinnabulation,' according to Burroughs (*Birds and Poets*), quite unequalled. His volubility borders on the burlesque. In disposition also the male is interesting; he affords the 'most marked example of exuberant pride, and a glad, rollicking, holiday spirit, that can be seen among American birds.' His love-making emotions appear to be unusually strong, as strong indeed as his Quaker mate is shy, retiring, and indifferent. The change of the male in colour and form at the breeding time is very striking. He becomes black and white more emphatically, so as sometimes to be called the 'skunk bird,' and acquires a broad form and a curious 'mincing gait.' Robert o' Lincoln becomes 'an ornithological coxcomb' of the highest order. He sings on brier and weed, or jerking up and down in the air, while his mate may be brooding in a simple nest among the grass. The bob-o-link is said to exhibit the common trick of seeking by exaggerated fuss in some other quarter to lead intruders away from the nest.

The bob-o-link is a bird of passage, spending the winter in the West Indies. In summer it is found as far north as the banks of the Saskatchewan, in 54° lat., but is most plentiful in the Atlantic states and other eastern parts of America, where it is to be seen in every meadow and cornfield. It renders good service by the destruction of insects and their larvæ; but in the South, both in April and August, at seed-time and harvest, it ravages seriously cripple the rice-growing industry, and destroy about a fourth of the crop. Thousands of men and boys are then employed to shoot the trespassers, who are killed in great numbers for the table; their flesh is delicate, and resembles that of

the ortolan. On account also of their beauty and powers of song, many are caught, caged, and sold in the New York and other markets.

Bobruisk, a fortified town of Russia, on the Beresina, 87 miles S.E. of Minsk by rail, with a large trade in wood and corn. It was besieged ineffectually by the French in 1812, and was made a fortress of the first rank by the Emperor Nicholas. Pop. 58,056 (very many of them Jews).

Bocage, Manoel du (1766-1806), a great Portuguese poet. See PORTUGAL, Vol. VIII. p. 341.

Boca Tigre (also Bocca Tigris, and in English Bogue), the Portuguese translation of the Chinese name *Hu-mun*, 'tiger's mouth,' given to a portion of the estuary of the Canton River (see CANTON). On its rocky islands are situated the Bogue forts, which have been more than once captured by the British.

Boccaccio, GIOVANNI, was born either at Paris or at Florence in 1313. He was the illegitimate son of a merchant of Certaldo, and at the age of ten was apprenticed to a merchant of Paris. Disliking commerce, he attempted but quickly abandoned the study of canon law, and was then sent by his father to Naples, with the intention that he should follow a mercantile career. At Naples he gave himself to story-writing in verse and prose; mingled in courtly society; and fell in love with the lady whom, under the name of Fiammetta, he has made as famous as the Beatrice of Dante and the Laura of Petrarch. In the *Filicopo* she is said to have been an illegitimate daughter of King Robert of Sicily; in the *Fiammetta* she is represented as a beautiful Neapolitan, of noble but not of royal descent. She appears in a number of Boccaccio's works, and is one of the story-tellers in the *Decameron*. Up to the year 1350 Boccaccio lived alternately at Florence and at Naples. Between 1340 and 1350 he produced the prose tale of *Fiammetta*; the *Aneto*, a pastoral piece; and the *Amorosa Visione*, in which he sang the praise of his mistress in *terza rima*. To the same period belong the *Filicopo*, the *Teseide*, and the *Filostrato*. In the *Filicopo* the story of *Flora et Blanchefleur*, one of the finest of the French 'Romans d'Aventures,' is cast into prose and embroidered with fanciful rhetoric, but is hardly improved in the retelling. The *Teseide* is a graceful version in *ottava rima* of the mediæval romance of Palamon and Arcite, the same story as forms the subject of Chaucer's *Knight's Tale* (a poem which is to a great extent translated from Boccaccio's), and of Shakespeare and Fletcher's *Two Noble Kinsmen*. The *Filostrato*, which is likewise in *ottava rima*, deals with the loves of Troilus and Cressida, a story which had become widely popular in various forms after the appearance in 1287 of Guido of Messina's Latin romance of Troilus and Briseis. The heroine's name was changed by Boccaccio, from whose poem Chaucer translated nearly half of his *Troilus*. The year 1350 may be taken as the beginning of a new period in Boccaccio's life. Until then it is a life given to song and love and adventure. Thenceforth, for some fifteen years, it is the life of an honoured citizen, of a diplomatist intrusted with important public affairs, of a scholar devoted to the cause of the new learning. During this period, in which he formed a lasting friendship with Petrarch, Boccaccio, as Florentine ambassador, visited Rome, Ravenna, Avignon, and the court of the Margrave of Brandenburg. In 1358 he completed his great work, the *Decameron*, which he had begun some ten years before. In 1360 he lodged in his house the wandering Greek scholar, Leontius Pilatus, whom he persuaded the Florentines to appoint to a Greek professorship, and by whose aid he was enabled to transcribe and forward to Petrarch prose

versions of the *Iliad* and the *Odyssey*. He for some time held a chair founded for the elucidation of the works of Dante, on whose *Divina Commedia* he produced a commentary, now mainly interesting from the light which it sheds on Florentine life in the 14th century. During his last years he lived principally in retirement at Certaldo, and would have entered into holy orders, moved by repentance for the follies of his youth, had he not been dissuaded by Petrarch. He wrote in Latin an elaborate work on mythology, *De Genealogia Deorum*, and treatises *De Claris Mulieribus*, *De Montibus*, &c. He died at Certaldo on the 21st December 1375.

Boccaccio ranks among the great writers of Europe in virtue of the prose tales of the *Decameron*. This famous book opens with a description of the plague at Florence in 1348. Seven ladies and three gentlemen are introduced, who leave the city and betake themselves in quest of security and distraction to a country villa. There they while away ten days (whence the name *Decameron*) by each in turn telling stories in the garden. In all, one hundred tales are thus told. Many of these are extremely licentious; others are full of pathos and poetical fancy; several are masterpieces of imaginative creation; all are related in exquisitely graceful Italian. Boccaccio selected the plots of his stories from amid the floating popular fiction of the day, and especially from the *fabliaux* which had passed into Italy from France. His originality lies in his consummate narrative skill, and in the rich poetical sentiment which transforms his borrowed materials. The influence of his great book upon European literature has been wide and profound. Among his countrymen, by whom he has been generally accepted as an almost incomparable master of Italian prose, he has found many imitators, the most notable being Firenzuola, Bandello, Cinthio, and Grazzini. In France the transformation of the *fabliau* into the *nouvelle* was partly due to the example set by Boccaccio. His influence is apparent in such collections of tales as the *Cent Nouvelles Nouvelles* ascribed to Antoine de la Salle, the *Grand Parangon de Nouvelles Nouvelles* of Nicholas of Troyes (1535), and the *Heptameron* (1558) of Marguerite of Navarre. Several of Boccaccio's stories are versified in the *Contes* of La Fontaine, in whose hands they assume a close resemblance to the form under which, as *fabliaux*, they had crossed the Alps into Italy. The debt of English writers to Boccaccio begins with the translations in Chaucer's *Troilus*. In the *Canterbury Tales* the stories told by the Reeve and the Franklin, and the story of Patient Griselda, are founded either on stories in the *Decameron* or on the same *fabliaux* as had been recast by Boccaccio. Sidney's *Arcadia*, says Mr Symonds, 'is a copy of what Boccaccio had attempted in his classical romances.' Cyril Tourneur's *Atheist's Tragedy*, Marston's *Parasitaster*, and Fletcher's *Women Pleased*, are examples of plays of which the plots were taken, wholly or partly, from Boccaccio. The scene of the caskets in the *Merchant of Venice* corresponds to a story in the *Decameron*. The plot of *All's Well that Ends Well* is taken from Boccaccio's story of Giletta and Beltramo, and the plot of *Cymbeline* is partly drawn from the ninth novel of the second day. None of Dryden's works have had more enduring popularity than his *Tales from Boccaccio*. In later days, Keats (in *Isabella*), Tennyson (in *The Falcon* and *The Lover's Tale*), Longfellow, Swinburne, and George Eliot are among those who have turned for their subjects to the deathless pages of the hundred tales.

Apart from the narrative interest and beauty of conception which mark its finest stories, the salient feature of the *Decameron* is the contrast between

the subjects and the style. The matter is medieval, while the form is classical. Boccaccio collected much that was choicest and most typical in the popular fiction of his day, and handed it down to modern times enshrined in imperishable language. The two great tendencies which run through European literature, the classical and the romantic, are seen working together in the *Decameron* as they are hardly to be seen elsewhere. The stories retain their medieval colour and flavour; yet the style preserves the classic dignity and elegance, the classic disdain of unessential detail. Despite the indelicacy of many of the novels, the impression left by the book as a whole is neither one of frivolity nor of grossness. The satiric malice and reckless levity of the *fabliaux* are replaced by a voluptuous melancholy, a refined pensive epicureanism. 'The central idea of the book,' says M. Emile Montegut, 'is that of love, represented as the chief motive force in social life, and the sovereign of the world. Love takes the place which fate held with the ancients, and which free-will holds among Christians.' The same line critic maintains that the tales have been carefully linked in the order best suited to enforce this central conception. Whether or not they were so arranged, the frame in which they are set is a masterpiece of literary art. The impressive account of the plague at Florence—the description of the burning noon-day calm, which recalled to Ampère the opening of Plato's *Phaedo*—the contrast which haunts the reader throughout the book, between death ravaging the world outside, and the quiet garden with its graceful inmates engrossed in song and story—the poetical fancy which invests Fiammetta and her companions with an undying charm—to these things there is no parallel in the works of Boccaccio's followers, as there is none to the golden perfection of his style.

See Baldelli's and Tiraboschi's biographies; German lives by Landau (1878), and Koerting (1880); Bartoli, *I precursori del Boccaccio*; studies by Crescini (1887); and J. A. Symonds, *Boccaccio as Man and Author* (1894).

Boccage, MARIE ANNE FIQUET DU (*née Le Page*), a French poetess, once famous, now almost forgotten, born at Rouen, 22d October 1710. She published a small volume of verse in 1746; next an imitation of Milton, *Paradis Terrestre*, in 1748; and in 1756, her most important work, *La Colombe*. Her letters to her sister, written while travelling through England, Holland, and Italy, are her most interesting work. During her lifetime she was excessively praised by men so great as Voltaire and Fontenelle; but modern readers cannot help thinking that her beauty must have recommended her verses. She was elected member of many learned academies, and died 8th August 1802.

Boccherini, LUIGI, composer, born at Lucca, 14th January 1740, studied at Rome, and appeared with great success at Paris in 1768. He next went to Madrid, and became chamber-composer to the Infante Don Luis, afterwards holding the same post under Frederick-William II. of Prussia. With the king's death in 1797, however, Boccherini's salary ceased, and the remainder of his life was darkened by poverty and ill-health. He died at Madrid, 28th May 1805. He wrote three hundred and sixty-six instrumental works, mostly trios, quartets, and quintets for strings, in which the cello is prominent; of his vocal works, a *Stabat Mater* for three voices has alone been published. Melodious, dignified, and displaying great originality, his best works are still esteemed.

Bochart, SAMUEL, a learned Protestant divine, was born of a good family at Rouen in 1599. He very early exhibited a remarkable aptitude for learning languages, and after extensive studies,

especially in the Semitic languages, at Paris, Sedan, Saumur, and Leyden, was chosen pastor of the Protestant church at Caen. Here in 1629 he gained great reputation by his victory in a public discussion of nine days' duration over the famous Jesuit, Verin. In 1646 he published his *Geographia Sacra*, a work of marvellous erudition. In 1652 he went to Stockholm along with his disciple, Huet, on the invitation of Queen Christina. The court-life, however, did not suit him, and his visit was short. His great work, *Hieroicoicon, sive de Animalibus Scriptura Sacra*, published in 1663, had afterwards the honour of being commended by Cuvier. He died suddenly, May 16, 1667. A complete edition of his numerous works was published at Leyden in 1712; and a new edition of the *Hieroicoicon* at Leipzig, in 3 vols. (1793-99).

Bochnia, a town of Austrian Galicia, 24 miles ESE. of Cracow by rail. Extensive mines of rock-salt employ upwards of 500 miners. Pop. 8894, a fourth of them Jews.

Bocholt, a town of Prussia, on the Aa, 13 miles N. of Wesel by rail, with manufactures of chicory, cotton goods, iron wares, and machinery. Pop. 13,034.

Bochum, a town of Prussia, 35 miles NE. of Düsseldorf by rail, a great centre of Westphalian industry. Its great steel-works employ over 5000 hands, and produce about 150,000 tons annually; armour-plating for ships, steel ropes and cables, machinery, files, tubing, safety-lamps, coal-tar substances, tin, roofing-felt, bricks, oil, and carpets are among its manufactures. There are great coal-mines near. Pop. (1871) 21,192; (1890) 47,601.

Boecland (i.e. book-land, or rather charter-land or deed-land), one of the early Anglo-Saxon forms of land tenure. Being proved by writing, it was distinguished from the Ethel, which had also been severed by an act of government from the Folcland (q.v.), and converted into an estate of perpetual inheritance, but which was proved by the pedigree of the owner and the witness of the community. It might belong to the church, to the king, or to a subject; it might be alienable and divisible at the will of the proprietor; it might be limited in its descent, without any power of alienation in the possessor. It was often granted for a single life or for more lives than one, with remainder in perpetuity to the church. It was forfeited for various delinquencies to the state, and was exempt from services, except the *fyrd* or military service, the repair of bridges, and the maintenance of fortifications. See Allen, *The Royal Prerogative*; Stubbs, *Constitutional History* (i. 76); Gneist, *Verwaltungsrecht* (i. 4); Robertson's *Early Kings of Scotland* (ii. 251).

Bode, JOHANN ELERT, astronomer, was born at Hamburg, 19th January 1747; in 1772 he became astronomer of the academy in Berlin, and in 1786 director of the observatory there. He published numerous astronomical works, including *Sternkunde* (3d ed. 1808), and *Uranographia* (2d ed. 1818), and founded the *Astronomische Jahrbücher*. He died 23d November 1826. The arithmetical relation subsisting between the distances of the planets from the sun, called after him Bode's Law, may be thus stated: Write, in the first instance, a row of fours, and under these place a geometrical series beginning with 3, and increasing by the ratio 2, putting the 3 under the second 4; and by addition we have the series 4, 7, 10, &c., which gives nearly the relative distances of the planets from the sun.

4	4	4	4	4	4	4	4	4
	3	6	12	24	48	96	192	384
4	7	10	16	28	52	100	196	388

Thus, if 10 be taken as the distance of the earth from the sun, 4 will give that of Mercury, 7 that of Venus, and so forth. The actual relative distances are as follow, making 10 the distance of the earth:

Mercury, Venus, Earth, Mars, Asteroids, Jupiter, Saturn, Uranus, Neptune.
3.9 7.2 10 15.2 27.4 52.9 95.4 192 300

Close as is the correspondence between the law and the actual distances, no physical reason has been given to account for it, although there is little room for doubt that such exists. Bode's law is therefore, in the present state of science, empirical. Kepler was the first to perceive the law, and Bode argued from it that a planet might be found between Mars and Jupiter, to fill up the gap that existed at the time in the series. The discovery of the Planetoids (see PLANETS) has proved the correctness of this prediction.

Bode. THE BARONS DE, a family known in England in connection with a claim for indemnity frequently brought before parliament. The claim was maintained by Baron Clement, the grandson of Charles de Bode, a baron of the Holy Roman empire, whose son, born in England of an English mother, was one of those originally included in the payment made by France in 1814 to indemnify British residents who had suffered by confiscation during the Revolution. As his estates had been held under German tenure, and he was not a British subject, the English government repudiated his claim in 1852. See *The Baroness de Bode*, by W. S. Childe-Pemberton (1900), a history of the family and its misfortunes.

Boden-See. See CONSTANCE, LAKE OF.

Bodenstedt. FRIEDRICH MARTIN VON, born in Hanover, 22d April 1819. In 1840 he went to Moscow as a tutor, and there translated Pushkin's poems. After extensive travels in the Crimea, Turkey, Greece, and Asia Minor, he returned to Germany in 1847, and published *Die Völker des Kaukasus* (1848). He edited for some years the *Weser Zeitung*, and in 1854 was appointed professor of Slav languages at Munich, afterwards obtaining also the chair of Old English there. These posts he resigned in 1866 for the superintendence of the Meiningen court theatre, which he retained only till 1873. Bodenstedt published many translations from the Russian, English (Shakespeare), and Persian, and several volumes of poetry, including dramas and romances. His most popular work is the *Lieder des Mirza Schaffy* (1851; 143d ed. Berlin, 1893), feigned to be a translation from the Tartar. He published his autobiography in 1890, and *Theodora*, a narrative poem, in 1892. He died in April 1892.

Bodin. JEAN, a great political thinker of the 16th century, was born at Angers about 1530. After his studies in law at Toulouse, he settled in Paris. By Henry III. he was appointed king's attorney at Laon in 1576, and by the Duc d'Alençon he was carried as secretary to England in his journey to solicit the hand of Queen Elizabeth. In the States-general at Blois in 1576 Bodin asserted with great energy and eloquence the rights of the people and freedom of conscience. The later years of his life were spent at Laon, the inhabitants of which he was able to persuade to declare for the League in 1589, and for Henry IV. five years later. Here he died of the plague in 1596. Bodin's greatest work is *Les Six Livres de la République* (1576), of which the author issued a Latin version in 1586. According to Bodin, property and the family form the basis of society, and a limited monarchy is the best possible form of government. In opposition to certain contemporary Protestant writers on politics, he held that under no circumstances are citizens justified

in rebelling against their ruler. One prince, however, may interfere in behalf of the oppressed subjects of another. Bodin's book is the greatest of its kind published during the 16th century; yet it had but little influence on contemporary opinion. His *Methodus ad Facilem Historiarum Cognitionem* (1566) is considered by some writers as having laid the foundation of the true philosophy of history. His famous *Colloquium Heptaplomeres de Abditis Rerum Sublimium Arcanis*, left in MS., and indeed not published until 1857 by Noack, is a conversation between a Jew, a Mohammedan, a Lutheran, a Zwinglian, a Roman Catholic, an Epicurean, and a Theist, who come to the conclusion that henceforward they will leave off disputing on religion, and live together in charity and toleration. Bodin, though so broad and liberal in his opinions as to earn the reputation of an atheist, was not before his age in his notions about witchcraft, as is evidenced by his *Demonomanie des Sorciers* (1580). See H. Baudrillart's *Jean Bodin et son Temps* (1853), and vol. i. of Flint's *Philosophy of History in Europe* (1874).

Bodle. an ancient Scotch copper coin of the value of two pennies Scots, or (about 1600) one-sixth of an English penny; said to have been so called from a mint-master of the name of *Bothwell*.

Bodleian Library. the public library of Oxford University, restored by Sir Thomas Bodley (q.v.) in 1598, his first act being the presentation of a large collection of valuable books, purchased on the Continent at an expense of £10,000. Through his influence and noble example, the library was speedily enriched by numerous other important contributions. Among the earliest subsequent benefactors of the Bodleian Library, which was opened in 1603, with a well-assorted collection of upwards of 2000 volumes, were the Earl of Pembroke, who presented it with 250 volumes of valuable Greek MSS.; Sir Thomas Roe; Sir Kenelm Digby; Robert Burton, author of the *Anatomy of Melancholy*; and Archbishop Land, who made it a magnificent donation of 1300 MSS. in more than twenty different languages. Upwards of 8000 volumes of the library of the famous John Selden (q.v.) went to the Bodleian Library. General Fairfax presented the library with many MSS., among which was Roger Dodsworth's collection of 160 volumes on English history. The greatest benefactor in the 18th century was Dr Richard Rawlinson, who, dying in 1755, left his complete collection of books and MSS. to the Bodleian Library. The MSS. amounted to upwards of 4800. George Ballard, who died in the same year (1755), bequeathed to the library 44 MS. volumes of interesting letters, with other valuable MSS. During the present century, the most important bequests have been the collections of Richard Gough, on British Topography and Saxon and Northern Literature; the choicest books from the library of Edmund Malone, the editor of Shakespeare; and the valuable books, prints, drawings, and coins of Francis Douce; also a sum of £40,000, by the Rev. Robert Mason, the interest to be expended on books. By purchase, the library acquired some magnificent collections of Oriental, Greek, Latin, and Hebrew books and MSS. The Bodleian Library is particularly rich in biblical codices, rabbinical literature, and materials for British history. By the Copyright Act it is entitled to a copy of every book printed in the United Kingdom. The number of volumes it possesses is estimated at about 460,000, in addition to between 20,000 and 30,000 in manuscript. The first catalogue of the printed books was published by the first librarian, Dr James, in 1605; the last, nearly two centuries and a half later (in 1843), in 3 vols., by

Dr Bandinel, the eleventh who held the office since the institution of the library. In the interval, several catalogues of various departments of the library were published; and a supplemental volume was added by Dr Bandinel in 1851. By statutes drawn up for the government of the library by Sir Thomas Bodley, it was decreed that the vice-chancellor, the proctors, and the regius professors of divinity, law, medicine, Hebrew, and Greek, should be visitors and curators; a statute passed in 1856 added 'five more residents to be elected by congregation for ten years, if continuing to reside, and to be re-eligible.' The library opens daily at nine o'clock in the morning; from April to July it closes at five; in February, March, August, September, and October at four; and in November, December, and January at three. It is shut during certain holidays, and for visitation purposes, in the aggregate, about 34 days in the year, besides Sundays. Since 1861 the domed Radcliffe Library (now *Cumera Bodleiana*) has served as a reading-room, open all the year from 10 A.M. to 10 P.M. Books neither rare nor valuable may be lent, by vote of Convocation, to persons working in other institutions of the university, and, by the authority of the librarian or curators, to professors of the university of Oxford. The history of the library is very carefully traced in the Rev. W. D. Macray's *Annals of the Bodleian Library* (1868; 2d ed. 1890).

Bodley, SIR THOMAS, the restorer of the library originally established at Oxford by Humphrey, Duke of Gloucester, was born at Exeter, March 2, 1543. His family, being forced to flee from England during the persecutions of Mary, settled at Geneva, where Bodley studied languages and divinity under the most distinguished professors of that city. On the accession of Elizabeth he returned to England and completed his studies at Oxford, where he took the degree of M.A., was afterwards elected a proctor, and officiated as public orator. He applied himself to the study of Hebrew, and four years spent abroad enabled him to become proficient in modern languages. He was now employed by the queen in diplomatic missions to Denmark, France, and Holland, and returned to his favourite city, Oxford, in 1597, where he devoted himself to literature, especially to the extension of the university library, now called the Bodleian (q.v.), in Bodley's honour. In collecting rare and valuable books from many parts of Europe, Bodley expended a very large sum, and also left an estate for salaries to officers, repair of the library, and purchase of books. He was knighted by King James, and died at Oxford, January 28, 1613. Having no family, he made the university his chief heir. Bodley's autobiography, extending to the year 1609, together with a collection of his letters, has been published under the title *Reliquiæ Bodleianæ* (1703).

Bodmer, JOHANN JAKOB, a Swiss poet and *littérateur*, was born at Greifensee, near Zurich, in 1698. The study of the Greek and Latin writers, together with the English, French, and Italian masters, having convinced him of the poverty and tastelessness of existing German literature, he resolved to attempt a reformation. Accordingly, in 1721, along with a few other young scholars, he commenced a weekly review, *Diskurse der Mäler*, in which the living poets were sharply handled. After 1740, when Bodmer published a treatise on the Wonderful in Poetry, a famous literary war broke out between him and Gottsched, the pedantic dictator of German literature. Bodmer's followers, the Swiss school, who were nourished on English poetry, maintained the claims of imagination and free poetic impulse against poetry according to hard and fast rules. The controversy partly prepared

the way for the Augustan epoch of German literature. Bodmer died at Zurich, where he had held the chair of History for fifty years, 2d January 1783. As an author, he was marked by inexhaustible activity; but his poems, dramas, and translations have no vigour or originality. He did greater service to literature by republishing the old German poets, the Minnesingers, and a part of the *Nibelungenlied*, as also by his numerous critical writings.

Bodmin, the county town of Cornwall, in the middle of the county, 30 miles NN.W. of Plymouth. It has some trade in cattle and sheep, and shoes are manufactured. The chief buildings are a market-house, the county hall, and the Cornwall Lunatic Asylum. Bodmin arose out of a priory, which, founded in 936 or earlier, came at the Reformation into Sternhold's hands. The church, rebuilt in 1472, has been restored since 1879. From the time of Edward I. till 1868, Bodmin returned two members to parliament; then, till 1885, one. Pop. (1891) 5151.

Bodock. See BOIS D'ARC.

Bodonì, GIAMBATTISTA, a distinguished Italian printer, born in Piedmont in 1740, settled at Parma in 1768, and died at Padua in 1813. His edition of the *Iliad* and of Virgil, as also his Lord's Prayer in 155 languages, are admired for their elegance. See the Life by Bernardi (1873).

Bödtscher, LUDWIG, one of the most finished poets the North has produced, was born at Copenhagen in 1793, and after a long residence in Italy, returned home in 1835, to die there in 1874. His poems are mainly love songs, and form but two small collections; but almost every one of them is a gem. See Gosse's *Northern Studies* (1879).

Body, HUMAN, will be treated of under the names of the several organs and functions, a list of which is given at ANATOMY.

Body-cavity, the space inclosed by the body-walls of an animal, and inclosing the gut and other organs. It acquires special names in different regions. In some cases, such as flat-worms, such a cavity is not present, either through non-development or in consequence of degeneration. In the Coelenterata (hydra, jelly-fish, sea-anemone) the body-cavity is not yet distinct from the alimentary system. The origin of the body-cavity is a very difficult problem which is not yet by any means satisfactorily solved. The brothers Hertwig have (1881) sought to distinguish two main ways in which the body-cavity arises—(a) from (ectodermic or mesodermic) pouches growing out from the primitive gut, and gradually inclosing it (*Enterocœla*), or (b) from a splitting in a solid middle layer or mesoderm, which does not arise as pouches from the gut, but appears in the form of indifferent cells budded in between the two primitive germinal layers. The latter set includes Molluscs, Polyzoa, Rotifers, and flat-worms, the cavity being undeveloped in the latter. The former set includes all the other classes. This view cannot be said, however, to be generally accepted.

Body Colour, a term applied to such pigments as have body enough to be opaque, as distinguished from those which are transparent. As a general rule, pigments have more body the nearer they approach to white; consequently the light parts of pictures in oil are in body colour to give them brightness and strength, while the dark parts are transparent to give them depth. Water-colour painting, when executed by mixing the pigments with white after the manner of an oil-painting, is said to be painted in body colour.

Body's Island, a long, narrow strip of sand, off North Carolina, with a lighthouse (150 feet), the highest in the United States.

Boece (or, more properly, **BOYIS**), **HECTOR**, a distinguished Scottish historian, was born of an old family about 1465 at Dundee. He completed his education at Montaign College, in the university of Paris, where from about 1492 to 1498 he was a regent or professor of Philosophy. Among other learned men whose friendship he acquired here was Erasmus. About the beginning of the 16th century he was invited by Bishop Elphinstone to preside over the university newly founded by him at Aberdeen. Boece accepted the office after some natural hesitation, the yearly salary being but 40 merks, or about £2, 4s. 6d. sterling. The value of money, however, it has to be remembered, was immensely greater then than now, and the learned principal was at the same time made a canon of the cathedral, and chaplain of St Ninians. During his tenure of office the university was highly prosperous and produced many excellent scholars. In 1522 he published his *lives*, in Latin, of the Bishops of Mortlach and Aberdeen. This work, a great part of which is occupied with the life of his excellent patron, Bishop Elphinstone, was reprinted by the Bannatyne Club in 1825. In 1527 Boece published the Latin *History of Scotland*, on which his fame chiefly rests, a work which, though proved to contain a large amount of fiction, was deemed distinctly critical at the time of its publication. The author was rewarded by the king with a pension of £50 Scots, until he should be promoted to a benefice of 100 merks, which appears to have occurred in 1534. By the excellence of his Latin style, and his sympathy with Erasmus, Boece may fairly be counted a humanist. He died in 1536, and was buried in the chapel of King's College. See BELLENDEN, JOHN.

Boeckh, **PHILIPP AUGUST**, classical antiquary, was born at Karlsruhe, November 24, 1785, and entered the university of Halle in 1803. The prelections of Wolf determined him to the science of philology, of which, in 1809, he became professor at the university of Heidelberg. In 1811 he was translated to the chair of Rhetoric and Ancient Literature at Berlin, where he lectured for upwards of forty years, and where he died, August 3, 1867. Boeckh's conception of philology as an organically constructed whole aimed at nothing short of an intellectual reproduction of antiquity, and consequently excited for a long time great opposition among his professional contemporaries, but it undoubtedly gave an impetus to a deeper study of the old classical world. His lectures include not merely a grammatico-historical interpretation of the ancient authors, but also archaeology proper, the history of ancient literature, philosophy, politics, religion, and social life. His four great works, which have in fact opened up new paths in the study of antiquity, are (1) his edition of Pindar (2 vols. 1811-21), in which the metre and rhythm of the poet, as well as his artistic skill, are investigated and discussed with profound knowledge of the subject; (2) *Die Staatshaushaltung der Athener* (2 vols. 1817; 3d ed. by Frankel, 1887), a work which remains unsurpassed for subtle research, surprising results, and clear exposition: it was translated into English by Sir George Cornewall Lewis under the title of *The Public Economy of Athens* (1828); (3) *Metrologische Untersuchungen über Gewichte, Münzfuss, und Masse des Altertums* (1838); (4) *Urkunden über das Seewesen des Attischen Staats* (1840). His lesser works are all valuable, and besides investigations in ancient chronology, editions of the *Antigone* of Sophocles (1843), and of the fragments ascribed to Philolaus (1819), and dissertations on Plato's cosmical system, include lectures and critiques collected under the title *Gesammelte kleine Schriften* (7 vols. 1858-74). Boeckh has also the honour of having commenced in

1824 the great work entitled *Corpus Inscriptionum Græcarum*, published at the expense of the Royal Academy of Berlin, which was continued by Franz, Kirchhoff, Curtius, and Röhl.

Boehm, **SIR JOSEPH EDGAR**, sculptor, was born in Vienna, July 6, 1834. He was educated from 1848-51 in England, and finally settled there in 1862. He had previously gained the first imperial prize in Vienna in 1856, and his work soon attracted notice in the country of his adoption. In 1867 he executed a colossal statue of the Queen, and afterwards received commissions for statues or busts of a large number of distinguished personages. Of the seated statue of Thomas Carlyle, enthusiastically praised by Mr Ruskin in his *Royal Academy Notes*, 1875, a replica was erected at Chelsea. His animal studies are also noteworthy. Boehm was elected a member of the Academy of Florence in 1875, an A.R.A. in 1878, and a member of the Academy of Rome in 1880. He was nominated in 1881 sculptor-in-ordinary to the Queen, and was made an R.A. in 1882, a baronet in 1880. The Queen's effigy on the coinage issued in 1887 was from his designs. He died 12th December 1890.

Boehme, **JAKOB**, a German theosophist and mystic, was born of poor parents at Altseidenberg, near Görlitz, in Upper Lusatia, 1575, and spent his boyhood in tending cattle. He received no instruction till he was ten years of age; but even then, the contemplation of earth and sky had so excited his naturally pious imagination, that he conceived himself inspired. He learned the trade of a shoemaker, and industriously followed that calling for most of his life, but continued to devote much of his time to meditation on divine things. About 1612 was published his first book, called *Aurora*. It contains revelations and meditations upon God, Man, and Nature; betokens a remarkable knowledge of Scripture, especially of the apocalyptic books; as also a familiarity with the writings of the mystico-philosophic alchemists, from whom he largely obtained his phraseology. It was condemned by the ecclesiastical authorities of Görlitz; but the persecutions to which its author was subjected had not the effect of convincing him of his errors. The chief aim of Boehme is to explain the origin of things, especially the existence of evil, and this he does by a mystical process of thought expressed in material symbols, which it is not easy to summarise.

God is the *Ungrund* or *Urgrund*, the original and undistinguished unity, at once everything and nothing, which, however, has in itself the principle of separation, whereby all things come into existence. It is through the principle of negation, which in a way is identified with evil, that creation is explained. His philosophy, in fact, is an application of the principle of contradiction to explain the great problems of philosophy and religion; but the difficulties are only concealed or shifted about under a cloud of mystical language, in which a system of triads, suggested by the Christian doctrine of the trinity, have an important place. In Boehme we have an obscure presentation of the thesis, antithesis, and synthesis, which have such a large application in the philosophy of Hegel. Numerous attacks from theologians disturbed Boehme's last years, but he bore them all with great meekness. So great was the interest excited, that he was induced by the solicitations of certain courtiers and of his friends to visit Dresden for the purpose of having his doctrines investigated. The court applauded and protected him. On returning to Görlitz, he fell ill, and died in 1624. The first collection of his writings was published by Betke (Amsterdam, 1675); the most complete in 1730, at the same place; and the latest (1831-46) by Schiebler, at

Leipzig. Next to Germany, Holland and England are the countries in which Boehme's works have been received with most favour. In England, where Boehme was generally called Behmen, all his works were translated between 1644 and 1662 (new ed. 1764). Sir Isaac Newton studied him; William Law of Oxford might be called a disciple; in 1697, Jane Leade, a fanatical disciple of Boehme, founded a sect, called the Philadelphists, for the exposition of his writings; and John Pordage, a physician, is also famed among his English interpreters. Abraham von Frankenberg, who died in 1652, published the earliest biography of Boehme. In modern times, and in connection with speculative philosophy in Germany, his views, which had come to be regarded as empty mysticism, have acquired fresh interest and importance. This arises from the kindred character of his fundamental principle with the spirit pervading the systems of Spinoza, Fichte, Schelling, and Hegel. See the works on Boehme and his philosophy by Hamberger (1844), Fechner (1857), Peip (1860), Harless (1870), and Martensen (Eng. trans. from Danish, 1885).

Boehmeria, a genus of Urticaceæ (q.v.), of which two species, or rather what were formerly considered as two distinct species, have been from a remote period cultivated in the East. The Indian variety was called by Roxburgh *Urtica tenacissima*, and the Chinese one *Boehmeria nivea* by Gaudichaud.

Boehmeria nivea :

a, male flower; b, glomerule of female flowers; c, single female flower; d, pericarp.

The fibre from *Boehmeria* has long been used in eastern countries for ropes and for cordage, and also for cloth in China and in Japan. This fibre is known in commerce as Rhea, as Ramie, or as China-grass, and if the most recent views of botanists as to the identity of several locally distinguished species of this plant which yields it be correct, it has a very wide range, being found in several parts of India, China, Japan, and the Eastern Archipelago generally. It has been successfully introduced into a number of foreign countries, including the Cape, Mauritius, Algeria, and the south of France; in America, California, Louisiana, and some of the West Indian Islands. It may be propagated by cuttings, which can be readily grown, by roots, or by suckers, and it thrives best in moist shady places in the tropics.

Rhea fibre of commerce, which is composed of the bast-fibres on the inner side of the bark of the plant, is difficult to separate in a state suitable for the manufacturer except by a somewhat costly process. Twice over, first in 1869 and again in 1877, the Indian government offered, besides smaller prizes, sums of £5000 for a machine which would

prepare it economically, but with no satisfactory result.

In some respects rhea is the most remarkable of all known vegetable fibres. For fineness, strength, and lustre combined it excels any of them. It can be spun at least as fine as flax, is stronger, and has a more silky lustre. Jute has also this lustre, but it has neither the strength of rhea, nor its capability for bleaching and dyeing. Rhea has the additional advantage of being liker wool in its nature than other plant-fibres, and it can be used as a substitute for long-stapled wool. The knowledge of these valuable properties has, for twenty years past, stimulated an almost ceaseless activity among ingenious persons interested in textile manufactures, in order to discover some process by which the fibre could be prepared at a price that would make its extensive use remunerative.

The pyuha fibre of the Himalayas is derived from *B. Paya*.

Boeotia, one of the ancient political divisions of Greece, extended between Attica and Megara on the south, and Locris and Phocis on the north, with an area estimated at 1120 sq. m., or a little larger than Cheshire. The mountain-closed country falls naturally into five divisions—the basin of the Lake Copais, now called *Topolias*, that of the Asopus, the plain of Thebes, and the coast-districts on the Euboean and the Corinthian Gulf. The principal stream was anciently called the Cephissus; which in the spring, when swollen by the rains, almost converted the Copaic plain into a lake. There were several subterranean channels for the outlet of the waters towards the Euboean Sea, but they were not sufficient to carry them off; and in the days of Alexander the Great a vast tunnel was cut in the rock for the discharge of the water. After this fell into ruin, the district became marshy and unwholesome; and it was not till 1886 that it was once more properly drained. The draining operations, carried on for five years by a French company, drained 60,000 acres of arable land, of which in 1896 17,000 acres were cultivated, 6000 were occupied by adjacent proprietors, while 35,000 were still partly in reeds, partly in pasture. Boeotia has always been fertile. Of the earliest inhabitants, the most powerful were the Minyæ, who were dislodged by the Boeotians, an Æolian people from Thessaly. The Boeotians excelled as cultivators of the soil, and were brave soldiers both on foot and horseback; but they were rude and unsocial, and took little part in the gradual refinement of manners and intellectual development of the rest of Greece, so that the name became proverbial for illiterate dullness. This was usually ascribed to their thick damp atmosphere. Yet their generals include Epaminondas; and among their poets and historians were Hesiod, Pindar, and Plutarch. The fourteen greater cities formed the Boeotian League, with Thebes at its head. Of this league, a shadow still remained down to the times of the Roman empire. See PLATEA, and THEBES.—Along with Attica, Boeotia now forms a province of the kingdom of Greece, with an area of 2425 sq. m., and a pop. (1879) of 185,364.

Boerhaave, HERMANN, the most celebrated physician of the 18th century, was born at Voorhout, near Leyden, December 31, 1668. In 1682 he went to Leyden, where he studied theology and oriental languages, and took his degree in philosophy in 1689. In 1690 he began the study of medicine, and took his doctor's degree in 1693. In 1701 he was appointed lecturer on the Theory of Medicine at Leyden, and in his inaugural lecture recommended to the students the ancient method of Hippocrates in medicine; but in 1703 his views had become greatly enlarged. In 1709 he was

elected professor of Medicine and Botany. About this time he published the two works on which his great fame chiefly rests, *Institutiones Medice* (1708), and *Aphorismi de Cognoscendis et Curandis Morbis* (1709), both of which were translated into various European languages, and even into Arabic. In the first work—a model of comprehensive and methodical learning—he gives a complete outline of the theory of medicine; in the second, a classification of diseases with their causes and modes of treatment. Boerhaave also rendered important services to botany. His best lectures include those delivered on his resignation of the office of rector of the university, *De Comparando Certo in Physiis* (1714), and *De Honore Medici, Servitute* (1736); in the latter of which he declares that to be the servant of nature is the highest aim of medicine. To combine practice with theory, he caused a hospital to be opened, where he gave clinical instructions to his pupils. Though so industrious in his own profession, he undertook in 1718 the professorship of Chemistry, and published in 1724 his *Elementa Chemiæ*, a work which did much to render this science clear and intelligible, and one that will always occupy a high place in the history of chemistry. His fame had meanwhile rapidly increased. Patients from all parts of Europe came to consult him. Peter the Great of Russia visited him; and it is even said that a Chinese mandarin sent him a letter, addressed 'BOERHAAVE, celebrated physician, Europe.' His character was amiable and unassuming, and tinged with a deep but cheerful piety. He died September 23, 1738, having realised from his profession a fortune of two millions of florins. See Burton, *Account of the Life and Writings of Boerhaave* (2 vols. Lond. 1743); Johnson, *Life of Boerhaave* (Lond. 1834).

Boerhaavia. See NYCTAGINACEÆ.

Boers (Dutch, 'agriculturists,' 'farmers'), the name applied to the Dutch colonists of South Africa who are engaged in agriculture and the care of cattle. The first settlement of the Boers at the Cape of Good Hope dates from the 16th century, and they have since been reinforced by Huguenots from France, but they retain in a pronounced form the old Dutch character, especially the old Dutch love of freedom. After the final cession of the Cape to England in 1814 they disliked the new government, especially its friendly policy to the natives and the emancipation of the slaves in 1833. Accordingly, in 1835, bands of them 'trekked' northwards. In this way they occupied Natal, the Orange Free State, and the Transvaal, seizing the lands of the natives as pasture-ground, and reducing them to a form of servitude. Some of the Boers who trekked from the Transvaal during English rule in 1874, settled in Portuguese territory. The Boers, though often ignorant and by no means scrupulous or humane towards the natives, are remarkable for their courage and powerful physique, and are good horsemen and splendid marksmen. See G. M. Theal's *History of the Boers in Southern Africa* (1887); A. H. Keane, *The Boer States* (1900); Conan Doyle, *The Great Boer War* (1900); also the articles NATAL, ORANGE RIVER COLONY, and TRANSVAAL, and books there cited.

Boëtius (more correctly BOETHIUS), ANICIUS MANLIUS SEVERINUS, a Roman statesman and philosopher, was born between 470 and 475 A.D. of a rich and illustrious family. His father had held the office of consul, but died while Boëtius was still a boy. Brought up under the care of men of rank, he studied with enthusiasm philosophy, mathematics, and poetry, translating and elucidating with laborious care the writings of Aristotle, Euclid, Archimedes, Nicomachus, and others. His talents soon attracted notice, and

having gained the esteem and confidence of Theodoric, king of the Goths, who had fixed the seat of his government at Rome in the year 500, he was appointed by that monarch *magister officiorum* in his court. His influence was invariably exercised for the good of Italy, and his countrymen owed it to him that the Gothic rule was so little oppressive. Boëtius was made consul in 510, and his good-fortune culminated in the prosperity of his two sons, who shared the same honour in 522. But his bold uprightness of conduct, springing apparently from his strong faith in the truth of his philosophic ethics, at last brought down upon his head the unscrupulous vengeance of those whom he had checked in their oppressions, and provoked by his virtues. He was accused of treasonable designs against Theodoric; and the king, having become despondent and mistrustful in his old age, was induced to listen to the charges. Boëtius was stripped of his dignities, his property was confiscated, and he himself, after having been imprisoned for some time at Pavia, was executed in 525; according to long subsequent accounts, with circumstances of horrible cruelty. During his imprisonment he wrote his famous *De Consolatione Philosophiæ*, in which the author holds a conversation with Philosophy, who shows him the mutability of all earthly fortune, and the insecurity of everything save virtue. The work is composed in a style which happily imitates the best models of the Augustan age, and the frequent fragments of poetry which are interspersed throughout the dialogue are distinguished by their truthfulness of feeling and metrical accuracy. The *Consolatio* is piously *theistic* in its language, but affords no indication that its writer was a Christian; and if the doctrinal treatises ascribed to him are, as the acutest criticism maintains, not genuine, we must class him in religion rather with Marcus Aurelius than with his alleged friend, St Benedict. Boëtius was the last Roman writer of any mark who understood the Greek language and literature. During the middle ages his translations formed to a large extent the medium by which men became acquainted with Aristotle; and his manuals on arithmetic, astronomy, geometry, and music were generally used in the schools.

Four editions of the entire works of Boëtius appeared between 1491 and 1847 (Migne). Of the *Consolatio* (often edited, as by Peiper in 1871) many manuscript translations into various languages appeared long before the invention of printing. Among these may be mentioned that by King Alfred into Anglo-Saxon (ed. by Fox, 1864). Chaucer's version in English prose was published by Caxton in 1480. Colville's translation (1556) was re-edited by Belfort Pax in 1897; another translation is by H. N. James (1897). H. E. Stewart's *Boethius: an Essay* (1891), holds that the philosopher was at least outwardly a Christian, and inclines to believe that the theological tractates ascribed to him were actually his work.

Bog is spongy land covered with peat. Bogs of great extent exist in some of the northern parts of the world. A very considerable part of the surface of Ireland is occupied with them. The Bog of Allen (see ALLEN, BOG OF) is the most extensive in the British Islands. The Solway Moss (q.v.), on the western border of England and Scotland, is about 7 miles in circumference. Chatmoss (q.v.) in Lancashire is 10 sq. m. in extent. There are large bogs in some of the Hebrides and the Orkneys. The swamps of the east of England are in general not peat-bogs, but consist chiefly of soft mud or silt.

The general surface of a bog is always nearly level, but it is usually varied with rushy tussocks rising above the rest, and having a rather firmer soil. By the continued growth of peat, the surface of a bog is gradually elevated; that of Chatmoss,

for example, rises above the level of the surrounding country, having a gradual slope of 30 or 40 feet from the centre to the solid land on all sides. Occasionally, the quantity of water becoming excessive owing to continuous rains, a *bog bursts*, and pours a terrible deluge down the course of a stream, causing great devastation, not only by the force of its torrent, but by the enormous quantities of peat which it deposits upon meadows and cultivated fields, as has happened in some memorable instances in Ireland. In December 1896 a large bog of 200 acres burst at Rathmore, near Killarney; several lives were lost, and many miles of country laid waste. The depth of a bog is sometimes more than 40 feet. The spongy mass of which it is formed shakes on the least pressure. Sometimes it is impossible to traverse it; in other cases, it is possible only for those who are well accustomed to it, a false step being a plunge into a quagmire, in which a man sinks as in a quicksand. Safety is sometimes insured by 'pattens'—boards fastened upon the soles of the feet—a method which has been also employed to enable horses to work upon the surface. Tradition reports that at the battle of Solway in 1542, a fugitive troop of horse plunged into the moss, which instantly closed upon them.

One of the remarkable phenomena of peat-bogs is the frequent presence of roots and fallen trunks of trees, in a good state of preservation, many feet below the surface (see *BOG-OAK ORNAMENTS*), and this frequently where no trees exist on the surface now. Hence it is inferred that in many instances these morasses originated in the decay or partial destruction of ancient forests (see the article *PEAT*). Bogs are popularly divided into two classes—*Red Bogs* and *Black Bogs*; the decomposition of the vegetable matter in the former being less perfect, and the substance, consequently, more fibrous and light than in the latter. There is indeed no precise line of distinction, and all intermediate conditions occur. The most extensive and deepest bogs are the red bogs; black bogs are more numerous. See *BOG-PLANTS*.

There can be no doubt that much of the land now occupied by bog is capable of being rendered very productive, whilst the effects of extensive bogs upon the climate are always injurious. The reclaiming of shallow mountain bogs is comparatively easy, and in some cases it is effected by a very simple and inexpensive drainage, and by throwing them at once under cultivation in a manner analogous to that known in Ireland as the *lazy-bed* method of planting potatoes—the soil upon which the bog rests being partially dugged up and thrown over its surface. Great difficulties, however, attend the reclaiming of red bogs; the chief being in some cases caused by the low situation of the bog, and the want of *fall* for drainage. Another serious obstacle is presented by the spongy substance of red bogs being extremely retentive of water, so that a deep ditch only drains a very narrow strip on either side of it. Drainage is certainly effective only when the drains are cut through the peat into the underlying soil, and this operation is often too costly. Where a good soil is known to exist below, the peat is sometimes removed bodily; thus it has been floated off, as in the long-continued operations at Blair-Drummond, on the banks of the Forth. A portion of the peat taken from the upper surface is not infrequently burned in heaps upon the spot, the ashes becoming a manure, and assisting in the formation of a soil.

Of course, the first essential in the reclaiming of bogs is drainage. The method of effecting this must be varied according to circumstances; but very frequently, after a general outlet with sufficient fall has been secured, wide open drains are cut, by which the bog is divided into strips,

which again are traversed and subdivided by smaller drains. When these drains begin to serve their purpose, the surface of the bog sinks, and their depth is reduced; they are then often deepened, and at last a permanent system of covered drains emptying themselves into open ditches is thus formed, and fits the land for all the purposes of agriculture. It is, however, often ploughed before this state of things is attained. Lime, calcareous sand, clay, and other manures are applied, according to circumstances, to promote the conversion of the peat into useful soil. Sometimes the first crop taken from the ploughed bog is a crop of oats; sometimes it is found preferable to begin with rape, turnip, or the like. In some places in the north of Ireland florin grass (see *BENT-GRASS*) has been sown on bogs in process of being reclaimed, and enormous crops have been obtained. See *WASTE LANDS*.

Bogardus, JAMES, American inventor, born in Catskill, New York, 14th March 1800, was apprenticed to a watchmaker, and early showed the bent of his mind by improvements in the construction of eight-day clocks, and by the invention of a delicate engraving-machine. The dry gas-meter is his invention, as is also the transfer-machine to produce bank-note plates from separate dies; and in 1839 his plan for manufacturing postage-stamps was accepted by the British government. Later he introduced improvements in the manufacture of india-rubber goods, tools, and machinery; and invented a pyrometer, a deep-sea sounding-machine, and a dynamometer. He died at New York, 13th April 1874.

Bog Asphodel (*Narthecium ossifragum*), a pretty liliaceous herb, with a characteristic raceme of small golden-yellow star-like flowers, common in early autumn on boggy mountain-sides in northern temperate regions.

Bogatzky, KARL HEINRICH VON, a German devotional writer, was born at Jankowe in Lower Silesia, 7th September 1690. Coming under the influence of Francke, the pietist, he studied theology at Halle from 1715 to 1718. He was a long time in the service of various noble houses of Silesia, and afterwards lived some years at the Silesian village of Glancla, engaged in the organisation of an orphanage there. In 1740 he was received into the family of the Duke of Sachsen-Saalfeld, and on the duke's death he removed to Halle in 1746, where he spent the rest of his life in writing books of devotion, and died 15th June 1774. His chief work is *Das goldene Schatzkastlein der Kinder Gottes*, which in 1893 had reached its 61st edition, and is well known in English translations as Bogatzky's *Golden Treasury*. He wrote also many popular hymns, which were collected in 1749 (3d ed., with 411 added, 1771). A new edition of his autobiography appeared in 1872.

Bog Butter (*BUTYRITE* or *BUTYRELLITE* of mineralogists), a very peculiar mineral substance, which is found in some of the bogs of Ireland. It is evidently of vegetable origin, and has been formed by the decomposition of the peat amidst which it is found. In composition and qualities it exhibits a general agreement with bitumen, asphalt, amber, and the other mineral resins; all of which are not improbably supposed to resemble it also in their origin, although perhaps it is the most recent of them all. It contains about 74 per cent. of carbon; its remaining constituents being oxygen and hydrogen in nearly equal proportions. In colour and consistency it much resembles butter, and at 124° F. it becomes liquid. It is not soluble in water, but is readily soluble in alcohol or ether.

Bogdanovich, IPOLYT FEDOROVICH, a Russian poet, born in 1743, became president of the

imperial archives in 1788, and died near Kursk in 1803. The mock-heroic *Dushenka* (1778), the best of his poems, is based on the story of Psyche, and is characterised by a refined and graceful style, and vivacious playfulness of language. His works were collected in 6 vols. (1810).

Bogermann, JOHANN, the president of the famous Synod of Dort, was born in 1576, at the Frisian village of Oplewert. After studying at Heidelberg and Geneva, he became pastor at Leenwarden, and soon distinguished himself by the active part he took in the hot religious controversies of his time, especially that against Arminius. In 1618 he was elected president of the Synod of Dort; but his name is now remembered only for the translation of the Bible into the vernacular, mainly by him, which soon became the standard Dutch version. He died in 1633, at Franeker, where he was primarius professor of Divinity.

Boghaz-Keni (ancient *Pteria*), a village of Asia Minor, in the province of Angora, 150 miles S. of Sinope. In its vicinity are remains of a vast temple, described in Van Lennep's *Travels in Asia Minor* (1870). The remarkable bas-reliefs here have been recognised by Professor Sayce as of Hittite origin.

Boghead Coal (TORBANITE or BITUMENITE), a seam met with in the Carboniferous system in the lands of Torbanehill, Bathgate, Scotland. It occurs in a regularly stratified manner, and is closely related to cannel coal. Very rich in volatile hydrocarbons, it was largely used in making Paraffin (q.v.) and Gas (q.v.), but is no longer worked in Britain. It is not properly a coal, but rather a *bituminous clay* or *shale*, and similar shales are found in various parts of the world.

Bog Iron-ore, a mineral of very variable composition, but regarded as consisting essentially of peroxide of iron and water; the peroxide of iron often amounts to about 60 per cent., the water to about 20. Phosphoric acid is usually present in quantities varying from 2 to 11 per cent. Silicic acid, alumina, oxide of manganese, and other substances, which seem accidentally present, make up the rest. Bog iron-ore occurs chiefly in alluvial soils, in bogs, meadows, lakes, &c. It is of a brown, yellowish-brown, or blackish-brown colour. Some of its varieties are earthy and friable, formed of dull dusty particles; some are in masses of an earthy fracture, often vesicular; and some more compact, with conchoidal fracture. It is abundant in some of the northern and western islands of Scotland, and in the northern countries of Europe generally; also in North America. When smelted it yields good iron (see IRON, ORES OF). Bog iron-ore owes its origin to the chemical action of organic acids arising from the decomposition of plants. These acids attack and dissolve the salts of iron which they meet with in the rocks and soils. The solutions thus formed, when they are exposed to the air, become oxidised, and iron is thus precipitated in the form of hydrous ferric oxide, which, along with the various impurities mentioned above, forms bog iron-ore. This mineral occurs frequently in boggy or badly-drained land, forming the hard ferruginous crust known in Scotland as 'moorland-pan.' Considerable accumulations of bog iron-ore or lake-ore occur in the bottoms of lakes in Sweden and Norway, forming with comparative rapidity on the shallower slopes where reeds grow more or less abundantly. According to Ehrenberg, the bog iron-ore in the marshes about Berlin owes its origin largely to diatoms, which separate iron from the water and deposit it as hydrous ferric oxide within their siliceous frustules.

Bog Moss. See SPHAGNUM.

Bog Myrtle, GALE, or SWEET GALE (*Myrica Gale*), an aromatic and resinous shrub, with small lanceolate and

serrate gland-dotted leaves, the only genus of the amnataceous sub-order Myricaceae. It covers large areas of bog and of wet moorland in northern regions, and was formerly put to many domestic uses. Its twigs were used to make beds, and to keep away moths and other insects, while its shoots and leaves served as a substitute for hops, its leaves were mixed

with tobacco, and wax was obtained from its berries. See CANDLEBERRY.

Bognor, a Sussex watering-place, 9½ miles SE. of Chichester by rail. Founded in 1786 by a London hatter, Sir R. Hotham, it has an iron pier (1865) 1000 feet long, and a good esplanade, restored since the great storm of 1876. Pop. (1861) 2523; (1891) 4096. For the geological strata called Bognor beds, see EOCENE SYSTEM.

Bog-oak Ornaments. In the peat bogs of Great Britain, Ireland, and other northern countries, trunks of oak, yew, fir, and other woods, which have been long buried, are often found of a dark colour and well preserved, owing to the antiseptic properties of the peaty water. Black oak so found is very suitable for turning and carving. In Dublin a considerable trade is carried on in bog-oak jewelry and other ornaments. The articles made are small models of Irish buildings, Paddy and his pig, brooches, necklaces, fans, crosses, and other trinkets. Upon some of these the harp and the shamrock are frequent adornments. Some patterns of the kind that used to be carved are now stamped by a heated die placed in a screw-press. Recent oak and other woods, stained black artificially, are much substituted for true bog-oak in these articles. The trade originated on the occasion of George IV.'s visit to Ireland in 1821. The annual value of the goods sold in Dublin has been estimated at fully £20,000, but the manufacture is capable of considerable development, if more attention were paid to the designs, which at present are often very inartistic.

Bogodukhof, a town of Russia, on the Merla, 43 miles NW. of Kharkoff. It has a cathedral, an important leather industry, and much trade in cattle. Pop. 11,525.

Bogomil'i (Slav., 'lovers of God'), a religious sect which arose in the 12th century within the Greek Church in Thrace and Bulgaria. Their theology was dualistic, and resembled that of the Paulicians and Cathari. Out of the eternal Divine Essence or Being sprang two principles—Sataael and Logos; the former, at first good, afterwards rebelled, and created in opposition to the original spiritual universe a world of matter and human beings. These human beings, however, received from the Supreme Father a life-spirit; but this was kept in slavery by Sataael until the Logos or

Bog Myrtle:

a, male catkin; b, female catkin.

Christ came down from heaven, and assuming a phantom body, broke the power of the evil spirit, who was henceforth called only Satan. The Bogomili practised a severe asceticism, despised images, and rejected the sacraments. They accepted the whole of the New Testament, but of the Old Testament only the Psalms and Prophets, which they interpreted allegorically. In 1118, that vehement hater of heretics, Alexius Comnenus, burned their leader Basilus. Persecution, however, did not put an end to the Bogomili, and to the time of the Mohammedan conquest of Bosnia (16th century), we find that the greatest number of the renegade Christians who embraced the religion of the conquerors belonged to this sect. See Gaster's *Greeko-Slavonic Literature* (1887); Heard's *The Russian Church and Russian Dissent* (1887).

Bogotá. under Spanish rule SANTA FÉ DE BOGOTÁ, in South America, the federal capital of the Republic of Colombia. It is situated within the limits of the province of Cundinamarca, on a tableland which, at an elevation of 8694 feet above the sea, separates the basin of the Magdalena from that of the Orinoco. The tableland has an area of about 400 sq. m., and is bounded on all sides by mountains which, though lofty enough to give shelter, are yet below the line of perpetual snow. This extensive plain—a temperate zone on the verge of the equator, with a salubrious climate and an average temperature of 60° F.—is exceedingly fertile, being as rich in pasture as in grain. The greater number of its people, however, are sunk in poverty. This is largely due to the heavy cost and difficulty of transport, which hamper all industries. Bogotá is 65 miles from its port, Honda, the head of navigation on the Magdalena; and from this point, although a railway has been projected, at present goods must be conveyed over the mountains in packages of not more than 125 lb. The transport of heavy machinery is thus impossible. The few manufactures of the place include soap, leather, cloth, and articles made from the precious metals. Bogotá was founded in 1538, and in 1598 became the capital of the Spanish viceroyalty of New Granada; since 1554 it has been the seat of an archbishop. In 1800 it contained 21,464 inhabitants, and in 1821, 30,000; in 1884, 95,813; and now, by estimate, about 100,000. Prospectively, the surrounding mountains promise one day to give to industry many valuable minerals, such as iron, coal, and salt. The last two, in fact, have already been obtained to some extent. Mines of emeralds, gold, silver, and copper are also said to exist within the same district. The town is regularly and handsomely built, although most of the houses have but one story, and little glass, owing to the prevalence of earthquakes. The streets are at right angles, and paved and lit, but not over clean. Bogotá teems with churches, its cathedral being famous for a statue of the Virgin, which is covered with costly jewels; its convents were suppressed in 1861. It likewise possesses, in addition to the capitol, a palace for the national chambers, and other official buildings, a mint, a university with six faculties, a number of schools, a free library, observatory, two theatres, and museums; and, supporting about forty journals, the city has been proudly named by its inhabitants the 'Athens of South America.'—The river Bogotá, otherwise called the Funcha, is in itself an object of physical interest. It is the single outlet of the waters of the tableland, which, both from geological features and from aboriginal traditions, appears to have once been a land-locked basin, somewhat like the still loftier and larger plateau of Titicaca. Be this as it may, the river has found, if it has not forced, a passage for itself towards the Magdalena. At the cataract of Tequendama the waters plunge

over a precipice 625 feet high, their force having hollowed out a well 130 feet deep in the rock below; and the clouds of spray clothe the adjacent ground in the most luxuriant vegetation. Some miles from the fall stands the natural bridge of Jeononzo, formed as if by the fortuitous jamming of rocks from the opposite sides of the cleft; and the plateau also contains a lake, Guatavita, into which the natives are said to have thrown their treasures when conquered by the Spaniards.

Bog-plants. The extensive areas, especially in the colder regions of the northern hemisphere, which are covered by bogs and marshes, have a highly characteristic flora which is distinct from the fully Aquatic Plants (q.v.) on the one hand, and from the ordinary terrestrial flora on the other. The most important and widely distributed of bog-plants are the bog-mosses (*Sphagnum*), of which the steady upward growth has formed the bulk of our peat-mosses; but higher cryptogamic plants also occur, notably the horsetails (*Equisetum*), and occasionally also rarer forms like *Pilularia* and *Marsilea*. Many sedges and rushes, reeds and grasses, are also highly characteristic, most of all perhaps the curious cotton-grass (*Eriophorum*), while heaths constantly struggle for possession of the drier and denser spots. The Bog-myrtle, q.v. (*Myrica Gale*) often overspreads vast areas with its low, scanty brushwood, above which rise only occasional tufts of willow, or at most here and there an alder. The insectivorous plants are perhaps the most characteristic minor denizens, sundews (*Drosera*) and butterworts (*Pinguicula*) being thickly strewn, while the rarer blossoms of the bladderwort (*Utricularia*) rise golden from their stagnant pools. The margins of these are fringed by the beautiful bog-bean (*Menyanthes*) and the smaller and less spreading forget-me-nots (*Myosotis*), or in spring are gay with marsh-marigolds (*Caltha*) and ranunculuses; while the brown blossoms of the marsh-potentilla (*P. Comarum*), the purplish-pink louseworts (*Pedicularis*), and the curious yellow-rattle (*Rhinanthus*) make their appearance later in summer.

The progress of agriculture completely destroys this flora, hardly a single bog-plant, save the versatile *Polygonum amphibium*, being able to survive thorough drainage. Many beautiful bog-plants can, however, be easily cultivated where a supply of standing water renders possible an artificial re-establishment of their natural conditions, or at anyrate, the continual soaking of their garden border, which should, of course, contain a large proportion of peat. For the geological agency of bog-plants, see PEAT.

Bog Spavin. This singular name has been applied to a lesion of the hock-joint of the horse, consisting in distension of the capsule inclosing the joint. Usually arising suddenly from a sprain in action, it most commonly affects young horses with defective hocks, and is associated with other indications of weakness in the injured joint. As the immediate result of a violent sprain, the hock becomes swollen, hot, and tender, and there is considerable lameness. The acute symptoms subside readily, but a circumscribed swelling remains towards the front, inner, and lower part of the joint. The swelling is firm and tense, and partly disappears during exercise, to again reappear after rest. At every recurring strain, lameness supervenes, but commonly passes off within a short time. If the bog spavin has accidentally occurred in a young horse with good hocks, it may after disappearance of the acute symptoms never again be attended with inconvenience. The treatment of bog spavin consists in the application of a high-heeled shoe, without a toe-piece, to the foot;

the administration of a purge, soft diet, and rest, and the application of fomentations and mild stimulations to the part, succeeded after a few days by blisters, and perhaps, in cases of persistent lameness, both firing and blistering. We can, however, only obtain a reduction in the inflammatory symptoms and disappearance of the lameness, but hardly ever a disappearance of the swelling. See SPAVIN.

Bogue, DAVID, one of the founders of the London Missionary Society, was in 1750 born in Coldingham parish, Berwickshire. He studied at Edinburgh, and was licensed to preach by the Church of Scotland, but went to London to teach in 1771. He afterwards became minister of an Independent chapel at Gosport, and here he also took a tutorship in a seminary for Independent students of theology. This became a great school of missionaries, and out of it grew the scheme for foreign missions realised in the London Missionary Society. Bogue also took an active part in the establishment of the British and Foreign Bible Society and the Religious Tract Society. He was on the point of going as a missionary to India in 1796, when the East India Company refused to sanction the scheme. Bogue died at Brighton, October 25, 1825. He published numerous books, including an *Essay on the Divine Authority of the New Testament*. In conjunction with Dr James Bennet, he wrote a *History of Dissenters* (3 vols. 1809), of great value, though somewhat impaired by partisan prejudices.

Boguslav, a town of Russia, 70 miles SSE. of Kieff. Pop. 9030.

Bohemia (Ger. *Böhmen*), formerly one of the kingdoms of Europe, now forms the most northern province of the Austro-Hungarian monarchy, touching Saxony and Prussian Silesia, Moravia, Upper and Lower Austria, and Bavaria. It has an area of 19,980 sq. m., or about two-thirds that of Scotland; pop. (1869) 5,140,544; (1880) 5,560,819; (1890) 5,843,094. It contains nearly 400 cities, of which the most important are Prague, the capital of the kingdom, and third city of the empire, with 184,109 inhabitants; Pilsen has over 50,000; Reichenberg has over, and Budweis just under, 30,000. The country is surrounded on all sides by lofty mountain-ranges, the principal of which are the Riesengebirge (part of the Sudetic chain) on the north-east, dividing Bohemia from Silesia, and attaining, in the peak of the Schneekoppe, a height of 5330 feet; on the north-west, the Erzgebirge, attaining a height of more than 4000 feet; on the south-west, the Böhmerwald, reaching 4783 feet. Offsets from these traverse the interior of the country, which has an undulating surface, sloping generally to the north. The country belongs to the upper basin of the Elbe, which rises in the Riesengebirge range; and it is well watered by the affluents of that river. The chief of these are the Moldau, the Eger, Iser, Aupa, Mettan, and Biela.

The climate of Bohemia is generally healthy, but varies greatly in different districts. In the valleys it is mild and pleasant, but raw and cold in the mountainous regions, where the higher peaks are covered with snow during a great portion of the year.

The mountain-chains which rise on all sides of Bohemia consist largely of primitive rocks, principally gneiss, mica-slate, and granite. Basalt, clinkstone, greenstone, and red sandstone are also common, and with the last, diluvial and alluvial deposits are met with, often to a considerable elevation. The extensive Silurian beds near Prague are rich in fossils. The plains belong chiefly to the Middle or Miocene period of the Tertiary formation, with sand, gravel, and marl.

A remnant of volcanic action, of which traces are common, still continues in the eruptions of carbonic acid gas which have established so many mineral springs of deserved repute, at Carlsbad, Eger, Marienbad, Teplitz, and throughout the country.

The mineral wealth is varied and extensive, consisting of silver, tin, copper, lead, iron, cobalt, bismuth, antimony, alum, sulphur, graphite, and porcelain clay, with several precious and ornamental stones. More coal is produced than in all the rest of the Austrian empire. The swampy plains yield an enormous amount of peat, and a large quantity of asphaltum is also obtained. On the other hand, no salt at all is found.

The soil is generally fertile. More than one-half of the area consists of arable land; nearly one-eighth is laid out in meadows and gardens; pastures form about a twelfth; and forests cover nearly a third. The wheat, rye, barley, and oats raised in Bohemia amount to more than a sixth of the produce of the whole Austrian empire. Flax and hops are plentiful, and a great variety of fruit is exported in large quantities. The culture of the vine is confined to the vicinity of the Moldau and the Elbe. Horned cattle, sheep, goats, and swine are reared extensively in some districts; bees and geese form important items in the resources of the country.

In manufactures, Bohemia holds a very high place among continental countries. It is a great centre of dyeing and calico-printing. The linen manufacture is more extensive than that of all the other Austrian provinces together, and the flax-spinning employs more than 235,000 spindles. The chief seat of the woollen manufacture is Reichenberg and its neighbourhood. Other important branches of industry are the manufacture of paper, ribbons, lace, chemicals, porcelain-ware, and the Turkish fez. The glass-works of Bohemia are celebrated, and very numerous and extensive, affording employment to some 27,000 persons. Beet-root sugar is manufactured extensively, and there are hundreds of breweries and brandy distilleries throughout the country, mostly on a small scale, although Bohemian beer is sold throughout Europe. The manufacture of iron is considerable. Its position secures Bohemia a large transit-trade. Steamboats ply on the Elbe and Moldau, and a canal crossing into Upper Austria conveys the timber of the Böhmerwald from the latter into the Danube. There are good roads and an excellent system of railways centring in the capital, Prague. There are nearly 3000 miles of railway, besides the branch lines for mining purposes.

Population, Religion, &c.—The Czechs, a Slavonic race, form the bulk of the people, and in 1890 constituted 62·8 per cent. of the total population, the other 37·2 per cent. being German. They dwell chiefly in the centre and east of the country. The German population reside mainly in the north-east and in the cities; their influence on industry, trade, and commerce is great in proportion to their numbers. The distinction between Czech and German is very sharply drawn. There are about 100,000 Jews. The vast majority of the population belong to the Roman Catholic Church, but other religions are tolerated; the Protestants only amount to 120,000, the majority belonging to the Calvinistic confession, and cherishing relations with the churches of Scotland. The Roman Catholics are under the supervision of the Archbishop of Prague and the three bishops of Leitmeritz, Königgrätz, and Budweis. The monasteries and convents number between 120 and 130. Education is much more widely diffused than in any of the other provinces of Austria. At the head of the educational establishments is the university of Prague, where since 1882 all subjects are taught in the German and

the Czech languages. Above 150 German professors have 1600 hearers, and 130 Czech professors, in what is practically a distinct university, have 2500 hearers. There are some 2200 German and 2500 Czech public schools, and numerous seminaries and technical institutes. Bohemia sends 54—about a fourth of the 203—members to the Lower House of the Austrian Reichsrath, or parliament of the western part of the empire.

History.—The country derives its name from the Celtic *Boii*, who were expelled by the Germanic Marcomanni about the beginning of the Christian era. The victors themselves soon gave place to others, and as early as the 5th century A.D. we find Bohemia peopled by the Czechs, a Slavic race. In the latter part of the 9th century, Swatopluk, the king of Moravia, subjugated Bohemia, and introduced Christianity. After his death, the dukes of Prague, who in 1086 had the title of king conferred on them by the Emperor Henry IV., ruled the country as a state in the German empire until 1306, when the last of the dynasty was assassinated.

From 1310 to 1437 the country was ruled by kings of the House of Luxemburg. In the time of Wenzel IV. (Wenceslas), a reformation of religion took place under John Huss (q.v.) and Jerome of Prague (q.v.). After the death of Wenzel IV., the imprudent measures adopted by the Emperor Sigismund excited a war of sixteen years' duration, which ended in making Bohemia an elective kingdom, and, in 1458, the shrewd and able Protestant noble, George of Podiebrad, ascended the throne. His successor, the Polish prince Ladislaus (1471–1516), was elected (1490) to the throne of Hungary, and removed the royal residence to Ofen, where also his son and successor, Louis (1516–1526), resided. After his death in battle against the Turks at Mohacz, Bohemia and Hungary passed into the hands of Ferdinand I. of Austria, who had married Louis's sister. From that time the history of Bohemia merges in the history of Austria (q.v.). The Reformation was tolerated under Maximilian, and religious liberty formally granted by Rudolf II. (1609). The withdrawal of this freedom a few years later under Matthias, and especially Ferdinand II., led to the troubles that broke out in 1618 and the election of Frederick V. of the Palatinate (q.v.) to be Bohemian king (see THIRTY YEARS' WAR). The battle at the Weissenberg (1620) restored the Hapsburgs, and was followed by the merciless extirpation of Protestantism, the suppression of all national privileges, and the ruin of the country. The reforms of Josef II. stirred up in Bohemia a revival of Czech feeling; and from 1848—when a rising was swiftly suppressed—onwards, there has been a continuous struggle between Germans and Czechs for the supremacy. A Bohemian diet elected under the new constitution of 1861 made the Czech language a compulsory subject even in German secondary schools. In 1867 the Czechs refused to send their complement of members to the Austrian Reichsrath, and showed their growing sympathies with Pan Slavism (q.v.). In 1879 they resumed attendance at the Reichsrath, and as a section of the Right secured further concessions in favour of the Czech tongue. The aim alike of the feudal and clerical old Czechs, and of the Liberal new Czechs, is the restoration of the full crown-rights of Bohemia, and the predominance of Czech ideas and the Czech language. See works cited at AUSTRIA; and those of Palacký (1836–60), Schlesinger (1870), and Tomek (1882), and, in English, of Count Lützow (1896), and E. C. Maurice (1896).

Language.—The Czech language, spoken in Bohemia, Moravia, and, with variations, among the Slovaks in the north of Hungary, is one of the most cultivated dialects of the Slavonic.

Its complicated and difficult forms remind one of the Latin and Greek accidence. Its peculiarities are the sibilated *r*, which is harsher than the *rz* of the Poles, and the distinct possession of both quantity and accent, so that the Latin and Greek metres can be exactly reproduced in it, though such imitations are purely artificial, the native poetry being accentual. Its syntax resembles Latin. It has one guttural, *ch*. It has a passive participle, but no formal passive voice, and makes a very free use of reflexive verbs.

Literature.—Bohemian literature divides itself naturally into three periods—(1) From the earliest time to the burning of Huss in 1415; (2) from 1415 to Josef II.'s Edict of Toleration in 1781; and (3) thence to the present time.

Period I.—The Greek Church is represented by a Glagolitic (q.v.) fragment (circa 900), the Latin by a fragment of St John's Gospel, with an interlinear Bohemian translation of somewhat later date. The greater part of the Bible was translated by the end of the 13th century, and in the 14th the whole was complete. A manuscript containing an unrhymed poem, the 'Judgment of Libussa,' was found in 1817, and another was found by V. Hanka, containing epic and lyric poems, all ascribed to the end of the 13th century. These manuscripts have both been attacked as forgeries, but it is difficult to conceive a forger in 1817 possessed of sufficient knowledge for the purpose, and microscopic examination has shown that Hanka both misread and misunderstood his manuscript in various places. The Latin *Alexandreis* was freely translated into Bohemian rhyme between 1240 and 1250, and legends of Christ and of several saints were current towards the close of the century.

The first half of the 14th century, the great event of which was the foundation of the university of Prague by Charles IV. in 1348, presents a rhymed chronicle, called that of Dalimil, the earliest complete manuscript of which (circa 1350) lay for one hundred and forty years unrecognised in the library of Trinity College, Cambridge, and was unearthed only in 1876. In this century didactic and satirical poetry were well represented. The rhymed legend of St Catherine (discovered at Stockholm in 1850) is of considerable beauty, and that of St Prokop is amusing. The travels of Marco Polo were translated early, and those of Sir John Mandeville late in the same century. A cycle of chivalry was also current. A complete Life of Christ was written. Romances of Alexander the Great and of Troy were translated. Tkadlec's dialogues between 'The Complainer' and 'Misfortune' are a model of terse and elegant Bohemian. Thomas of Stitný (1373–1400) wrote, in order that higher matters might become generally accessible in the Bohemian as well as in the Latin tongue, first for the instruction of his children, and then for a wider circle, considering that 'the soul of a Bohemian was as precious to God as that of a Latinist.' Theologian, homilist, and philosopher, his equal cannot be found in English literature before the time of Elizabeth. As a writer it is impossible to separate John Huss (Jan Hus) from Stitný. Huss's activity lay between 1402 and 1415, first as a preacher, and then as a writer. His Latin works, except those written without books in prison, are little more than centos and adaptations of Wyclif; but his Bohemian writings are very different, though he apparently still used Wyclif as an encyclopedia. He wrote a long work on the Creed, the Lord's Prayer, and the Ten Commandments, sermons on the Gospels for every Sunday in the year, and many smaller treatises, the most beautiful of which is the *Daughter*, a manual of advice to the human soul. His Bohemian style is inferior to that of Stitný.

Period II., from 1415 to 1781.—The Hussite wars were not favourable to any but controversial literature. After the suppression of the military Taborites (1452), the teaching of Peter Chelczický, a great religious writer and thinker (1430–56), was adopted by the peaceful Bohemian brotherhood. But for many years the brethren disregarded human learning, until, under the influence of Jan Blahoslav, the translator of the New Testament, who first noticed the capacity of Bohemian for representing the classical metres, they proceeded in earnest to their new translation of the Bible, which was printed in 6 vols. at Kralitz, in Moravia (1579–93). In poetry the Hussite times produced a few songs, satirical and didactic poems and ballads, among which are a spirited ballad on the battle of Aussig, and the war song of Ziska's soldiers on the march. Jan Ziska's military arrangements, which still exist in writing, are very remarkable. The *Diary of an Embassy from King George to King Louis XI. of France* (1464) is of historical rather than literary interest. During the Polish dynasty (1476–1524) John Hasensteinský wrote *Travels in Palestine* (1492) and *Advice to his Son* in excellent Bohemian, and Nicholas Konacz a grand book on the *Plaint of Justice, the Queen and Lady of all the Virtues*. Under Ferdinand I. and Maximilian II. (1526–75) the study of the classics was much advanced by the Jesuit academy established at Prague in 1555. Many of the Jesuits wrote in Bohemian with great success. Sixtus of Ottersdorf's *Memoirs of the Years 1546–47*, so fatal to Bohemian freedom, are very valuable. But the literary glory of this era is the *Kronyka Ceská* of V. Hajek of Liboczan (1541), which in style rivals Herodotus, though its historical statements are so untrustworthy, that Palacký terms him 'the corrupter of Bohemian history.'

The time of the emperors Rudolf II. and Matthias (1576–1619), or rather of the former, has been termed the 'golden age' of Bohemian literature, although little rises much above mediocrity. But educational arrangements were excellent, and probably superior to those of any other country in Europe. The centre of literature in Rudolf's time was the printer Adam of Veleslavin. Translations were more abundant than original works. Matyas Gryll (1592) wrote the only good original poem, 'On the Providence and Government of God,' of this era. The travels of Harant of Polzie in Palestine, Egypt, and Sinai have been translated into German, and the adventures of Wratislav of Mitrovitz in Turkey, into German, English, and Russian. Of Jirzik Zaveta's *Schola Aulica*, Balbinus said that, 'if translated into Latin, it need fear no criticism.' The greatest literary man among the Brethren was J. Amos Komenský (Comenius), the author of the *World in Pictures* and the *Labyrinth of the World*. From Ferdinand II. (1619) to Josef II. (1781) is a period of literary decline, succeeded by slumber. The Jesuits from the school of Ferdinand I. gradually died out, and their successors did not study Bohemian, but simply carried on an indiscriminate crusade (till 1760) against the native literature, one Jesuit boasting of having himself destroyed 60,000 volumes.

Period III., from Josef II. (1781) to the present time.—We now come to the unexampled resuscitation of a dead and buried language and literature. The Abbé Josef Dobrowský, the father of Slavonic comparative philology, devoted his life to grammatical, philological, and historical research, but wrote principally in Latin and German. In 1795 Fr. V. M. Kramerius established a Bohemian printing-press which, till his death in 1808, was the centre of Czech literary activity. In 1806 Jan Nejedly issued the first periodical, the *Hlasatel*

(Herald), in the Bohemian language. Dobrowský unfortunately constructed a prosody intended to reproduce the classical metres by accent irrespective of quantity, which was very embarrassing to poetry till overthrown (1818) by Palacký and Szafarzik (Schafarik). Still A. J. Puchmajer (1795–1814) is justly considered the reawakener of the Czech muse. The stores obtained by the researches of Dobrowský were edited in the *Starobylá Skladanie*, 'Ancient Collections' (1817–24), by V. Hanka, who also first successfully imitated the popular songs and ballads of the peasantry (1815–16). But the greatest impulse to Bohemian poetry was given by the 13th-century manuscripts above mentioned.

In 1818 Count Kaspar Sternberg and others succeeded in fully establishing and endowing the Bohemian Museum, which became the centre of research and progress. In 1819 appeared the first great poem of the revival, Polák's *Sublimity of Nature*. Next came J. Kollár, Fr. L. Czelskowský, and the Slovák Jan Holý. In 1821 J. S. Presl established the scientific magazine *Krok*, and ere long created a Bohemian terminology for chemistry and other sciences. In 1825 Jungmann published his *History of Bohemian Literature*. In 1827 the magazine (*Časopis*) of the Bohemian Museum appeared under the editorship of Fr. Palacký in Bohemian and German. Contrary to expectation, the circulation of the German monthly dwindled to nothing, while that of the Bohemian quarterly rapidly increased. In 1831 the Matice Česká, a bye-committee of the museum, was instituted for the republication of old and the publication of new works of value in the Bohemian language. By its aid J. Jungmann's gigantic Bohemian dictionary, the work of thirty years, appeared in five large volumes (1835–39), and in 1837 Szafarzik's *Slavonic Antiquities*, the first Bohemian work that obtained a European reputation. In 1831 Fr. Palacký was elected historian to the Estates of Bohemia. After searching the principal archives of Germany and Italy, especially the Vatican Library, he brought out the first volume of his history in German in 1836, in Bohemian not till 1848, the year of the abolition of the Austrian censorship of the press. In 1849 J. A. Purkyně, a physiologist of European reputation, effected the establishment of the periodical *Zira* for natural science. Other periodicals became numerous. Palacký's *History* (to 1526) was completed in German in 1867, in Bohemian not till 1876, the excisions and interpolations of the censorship being rectified. It was continued by Gindeley (1829–92). The translation of Shakespeare's dramatic works was completed (1854–72). K. J. Erben deserves especial notice as poet, archaeologist, translator, and editor of Huss's Bohemian works (3 vols. 1865–68), of Stitný, &c. V. V. Tomek, besides his history of the university of Prague (1849), is author of an exhaustive history of the city of Prague (vols. i.–vii. 1855–85). He was justly appointed the first rector of the re-established Bohemian University of Prague (1882).

Bohemian Brethren, a religious society, instituted in Prague about the middle of the 15th century, originally composed of remnants of the Hussites. In 1453 they settled on the borders of Silesia and Moravia. The Thirty Years' War entirely broke up the societies of the Brethren; but afterwards they united again, though persecuted. Their exodus and settlement in 1722 on the estates of Count Zinzendorf (q.v.) in Saxony, occasioned the formation of the Herrnhuters. See MORAVIANS.

Bohemond I., eldest son of Robert Guiscard (q.v.), was born about 1056, and during his youth distinguished himself in his father's war against the

Byzantine emperor, Alexius Comnenus (1081-85). After his father's death he was excluded from the throne of Apulia by his brother Roger, and only gained the principality of Tarentum after a long contest. He joined the crusade of 1092 with a large army—most of which he had won over from his brother's service—and took a prominent part in the capture of Antioch (1098). While the other crusaders advanced to storm Jerusalem, Bohemond remained in Antioch, where he established himself as prince, and routed the besieging forces of the sultan. He was afterwards made prisoner by a Turkish emir, and remained two years in captivity. Tancred, meanwhile, looked after his interests in Antioch. Bohemond returned to Europe to collect troops, and after defeating Alexius in several engagements, was acknowledged by that emperor as Prince of Antioch. He died in Apulia (1111). His son assumed the government of Antioch in 1126, and was killed in battle (1130).

Böhme. See BOEHME.

Böhmisch-Brod, a town of 4000 inhabitants, 20 miles E. of Prague by rail, near which the Hussites (q.v.) were defeated in 1434. See PROKOP.

Bohn, HENRY GEORGE, publisher, was born in London, January 4, 1796. His father, a German, was a bookbinder, and latterly a second-hand bookseller, and young Bohn, adopting the latter business, in 1831 started on his own account, amassed many valuable old books, and in 1841 issued his famous 'guinea catalogue,' containing 23,208 articles. Next he tried the 'remainder trade, and in 1846 he began the issue of the series of works with which his name is identified. It is impossible to estimate too highly the services he has rendered to the community by republishing, at a cheap rate, a vast number of the most valuable works in literature, science, philosophy, theology, &c. The whole eventually numbered over 600 volumes. He also edited the *Bibliotheca Patristica*, Lowndes's *Bibliographer's Manual*, &c., and issued translations of Schiller, Goethe, and Humboldt, besides a *Handbook of Proverbs*, and a *Dictionary of English Poetical Quotations*. After retiring from business in 1864, his chief stock, copyrights, and second-hand books, realised about £100,000. The china and art collections, sold both before and after his death, realised £45,000. He died August 22, 1884.

Böhtlingk, OTTO, Sanskrit scholar, was born in 1815 of German ancestry at St Petersburg; from 1835 to 1842 studied oriental languages, especially Sanskrit, at Berlin and Bonn; and, after twenty-six years in his native city, settled in 1868 at Jena. Among his invaluable works are the first European edition of the Indian grammarian Panini (1839), a Sanskrit Chrestomathy (1845; 2d ed. 1877), and a great Sanskrit dictionary (7 vols. 1855-75). In 1888 he celebrated his jubilee.

Bohun, THE FAMILY OF, was founded by the Norman Humphrey de Bohun, and in 1199 the head of the house became Earl of Hereford. The then Earl of Hereford was taken prisoner at Bannockburn, and a kinsman was slain in single combat by Bruce. In 1380 the heiress of the earldoms of Hereford, Essex, and Northampton, married Henry Bolingbroke (Henry IV.).

Boiardo, MATTEO MARIA, Count of Scandiano, one of the greater Italian poets, was born in 1434 at Scandiano, a village situated at the foot of the Lombard Apennines. He studied at the university of Ferrara, and in 1462 married the daughter of the Count of Norellara. He lived principally at the court of Ferrara on terms of intimate friendship with Duke Borso and Duke Ercole, by the latter of whom he was employed on important

diplomatic missions, and appointed in 1481 governor of Modena, and in 1487 governor of Reggio. As an administrator he was distinguished for his clemency, and is said to have held that no crime should be visited with capital punishment. He died at Reggio in 1494. Boiardo has been called the 'Flower of Chivalry.' His fame rests on the *Orlando Innamorato* (1486), a long narrative poem in which the romances of the Carolingian cycle are recast into *Ottava rima*. Full of rich and graceful fancy, this is the only work in which the spirit of chivalry is found in union with the spirit of the Renaissance. The chief characters, the Paladins of Charlemagne, are led in a maze of adventure from Paris to Spain, Hungary, Africa, and the far East; Orlando, whose love for the eastern princess Angelica is the central subject, being none other than the hero of the old *Chanson de Roland*. Ariosto adopted Boiardo's characters and magic machinery, and brought his narrative to a close in the *Orlando Furioso*, by which the fame of the earlier poem has been unfairly obscured. After going through sixteen editions before 1545, Boiardo's work became almost forgotten, its vigorous but rough and provincial style being uncongenial to the Florentine taste. Boiardo's other works comprise various Latin eclogues, a versification of Lucian's *Timon*, translations of Herodotus, the *Ass* of Lucian, and the *Golden Ass* of Apuleius, and a series of sonnets and *Canzoni* (Reggio, 1499). The best edition of Boiardo is by Panizzi (9 vols. Lond. 1830). See also Symonds's *Renaissance in Italy*.

Boieldieu, ADRIEN FRANÇOIS, an eminent French composer, was born at Rouen in 1775. His talent for music was early developed. At the age of eighteen he brought out a one-act opera in his native town, and two years afterwards he repaired to Paris, where he produced many successful compositions. When the Conservatoire de Musique was established, Boieldieu was elected a professor. The *Culiphe de Bagdad* (1799) was his first brilliant success. His unhappy marriage with the celebrated dancer, Clotilde Mollenroy, induced him to accept an invitation to St Petersburg, where from 1803 to 1810 he filled the post of imperial *maître de chapelle*, wrote the music to Racine's *Athalie*, and produced several operas. Returning to Paris, he brought out *Jean de Paris* (1812), *La Dame Blanche* (1825), his masterpiece, and other popular works. His strength lies in bright and graceful melody, light but tasteful instrumentation, and pure harmony. He has been called 'the French Mozart.' He was elected an academicien in 1817, and on his death, 8th October 1834, the nation honoured him with a public funeral. His native city claimed his heart, and in 1875 erected a monument to him. The government further marked its sense of his merit by granting a pension to his son Adrien (1816-83), who himself composed several operas. See Pongin, *Boieldieu, sa Vie, ses Œuvres* (1875).

Boii, a powerful Celtic people who dwelt originally in Transalpine Gaul, part of whom settled in the modern Bohemia, and bequeathed their name to that country.

Boil (Old Eng. *byl*, Middle Eng. *bile*; akin to prov. Eng. and Scotch *beal*, 'to suppurate'; its present spelling having arisen through confusion with the verb *boil*, which is from the French) is a hard painful swelling of the skin. It usually begins as a small hard point of a dusky red colour, which is hot, painful, and throbbing. This point extends, and these symptoms increase in severity till sooner or later, when the boil ceases to enlarge, it is of a conical form, with a broad firm base, and on the apex a whitish blister, which contains a little

matter; this opens, and after a few days more there is discharged the *core*, a little pellet of dead cellular tissue, and the small cavity left heals rapidly, leaving a white depressed scar. Sometimes boils subside without any breach in the skin, or any discharge. These are known as *blind* boils, and are generally less conical in shape, less painful, and slower in their progress than the common form. Boils rarely occur singly: very often the subjects of them suffer from successive crops during a period of some weeks or months. They may affect any part of the skin, except the palms of the hands and soles of the feet.

Boils are probably always caused by some abnormal condition of the blood or the nutrition of the body, though they often occur in people who appear to be in good health. They are most common in spring; are rare in young children, most frequent in older children and young adults. Any sudden change in diet and daily habits is very apt to cause them; thus persons undergoing a course of hydropathic treatment, or training for races, and country girls going into town as domestic servants, are very apt to suffer. They often occur also during recovery from exhausting diseases. 'In many cases they must be looked upon as salutary. After an outbreak of boils, the health often gradually improves' (Erichsen).

The best application to a boil in the early stages is collodion, frequently repeated, which often prevents its further development. Later, when the pain is severe, frequent bathing with hot water, or the application of small hot poultices, which may be made of poppy-heads, or of oatmeal or linseed-meal, will give relief and hasten the progress of the case. Incision is sometimes advisable if the patient's suffering is great. The constitutional condition must always be attended to, and any error in diet or habits corrected. Aperient medicines are generally useful, with, in enfeebled conditions, tonics; in plethoric conditions, alkalies. Sulphide of calcium, in doses of a tenth to a quarter of a grain, greatly hastens the ripening of boils, and prevents the formation of fresh ones.

Boileau. NICOLAS, was born at Paris, where his father was a registrar in one of the law-courts, on the 1st November 1636. He was educated at Beauvais, and received both a legal and a theological training. In his twenty-first year, however, he inherited a competence, and decided to follow a life of purely literary activity. In his youth he appears to have been most generally known by the surname Despréaux, which he had taken in accordance with a practice of the time. He published his satirical *Adieu d'un Poète à la Ville de Paris* in 1660, and in 1663 we find him united with Molière, La Fontaine, and Racine, in the famous 'society of four.' In 1666 he published a collection of satires from which the royal privilege was for a time withdrawn, through the influence of Chapelain, one of the writers whom he had gibbeted. Boileau, however, soon gained the favour of the king, who awarded him various pensions, and in 1677 appointed him, along with Racine, to the post of royal historiographer. *L'Art Poétique*, which contains the exposition of his literary creed, and which was imitated by Pope in the *Essay on Criticism*, was published in 1674, along with four cantos of the *Lutrin*, a clever serio-comic description of an ecclesiastical squabble over a reading-desk. Two cantos, concluding the poem, appeared in 1681. Between 1669 and 1677 Boileau published nine epistles, written, like his satires, on the Horatian model. To celebrate the capture of Namur in 1692, he composed an ode which remains a glaring example of servile flattery and bad verse. This deplorable production was admirably burlesqued by Prior. In his last years Boileau retired

to Auteuil, where he died on 13th March 1711. His works include several critical dissertations in prose, a collection of epigrams, a translation of Longinus *On the Sublime*, a *Dialogue des Héros de Roman*, and a series of letters, a number of which are addressed to Racine, extending from 1672 to 1710. He appears to have been of a jealous, arrogant nature, but not without generosity. Though he secretly preferred Corneille to Racine, he did his best to exalt the younger at the expense of the elder dramatist. Nevertheless, when Corneille's pension was stopped, he is said to have made a courageous protest to the king against 'so barbarous a spoliation.' His verse has wit and vigour, but he never rises to the level of the great satirists. His influence as a critic has been profound. The 16th century had flooded French literature with new words and new ideas. The riches which it had imported and developed required to be sifted, refined, and reduced to order. This task, which had been begun by Malherbe, was carried out with drastic energy by Boileau. He set up good sense, sobriety, elegance and dignity of style as the cardinal literary virtues. He discountenanced the conceits of the salon coteries, and the grossness and grotesqueness of the earlier writers. Through his influence more than any other man's, French prose became almost identical with clear, precise, and polished composition. But for more than a hundred years, while his authority was at its height, there was a distinct falling-off in poetry. Verse was robbed of fire and melody and the power of vague suggestion. The drama was divorced from real life, and restricted to certain prescribed situations and conventional characters. Boileau led Frenchmen to look with ignorant contempt on the nation's early literature. While he refined he impoverished the vocabulary. The language lost its old pith, colour, and flexibility, and became for a time incapable of reflecting vivid passion or complex character. Boileau's immense influence has thus been both beneficial and hurtful to French letters. For more than a hundred years he was accepted by his countrymen as the infallible 'lawgiver of Parnassus.' His authority has been reduced to a closer conformity with his deserts since the rise of the French Romantic school. See Fournier's edition of Boileau (Paris, 1873), and Laverdet's *Correspondance de Boileau* (Paris, 1858).

Boiler, the name given to a vessel in which steam, usually for a steam-engine, is generated. In its simplest form, it consists of a close vessel made of metal plate, having apertures for the admission of water and egress of steam, fitted with apparatus for showing the level of the water and the pressure of the steam, and in connection with a furnace, either internal or external. When water is boiled in an open pan, the temperature of the water and of the steam rising from it remains at or very near 212° F., and the tension or pressure of the steam is no more than sufficient to make its way into the atmosphere, being exactly equal to that exerted in all directions by the atmosphere itself—namely, 14·7 lb. per square inch. In a close vessel, on the other hand, the temperature and pressure to which we can raise the steam are only limited by the strength of the vessel or boiler against bursting.

The form of a boiler is determined by two considerations—namely, strength to withstand internal pressure, and efficiency in producing steam; and the object of the designer is to combine in one apparatus sufficient strength to work safely at the proposed pressure, with such a form and arrangement as shall abstract the maximum of heat from the gases of combustion, and at the same time be in all respects suitable to the special circumstances of the case. The globular form is that best adapted

for strength, and was the earliest to be used. It presents to the fire, however, the minimum area in proportion to its contents, and therefore has a minimum efficiency. After spherical boilers, cylindrical ones came into use, at first set on end, and afterwards laid on their sides, and later on, these were furnished with internal cylindrical tubes for furnaces. Watt's 'wagon boiler' (so called from its shape) was used for many years, but being quite unfit for any but the lowest pressures, it has long been discarded; and the 'egg-end' boiler, or plain cylinder with hemispherical ends, also much used at one time, has now almost disappeared on account of its small evaporative efficiency. At present, it is quite common to use a working steam-pressure of 60 to 80 lb. per square inch in ordinary factory boilers, and in some cases this is already greatly exceeded, while the tendency to use higher pressures seems to grow yearly. Already in marine work and elsewhere pressures of 120 to 150 lb. per square inch are as common as half those pressures were fifteen years since. Under these pressures, the only forms of boiler which can be used without heavy and expensive internal stays to prevent the danger of bursting, are the globular and the cylindrical. The former shape is rejected for the reason already given, and the latter form is used almost invariably in the construction of modern boilers, as will be seen from the examples given below. The ends of the cylinders, when it is necessary to make them flat, must, of course, be strengthened by stays.

Boilers may be classified in several ways—as (1) Horizontal and Vertical; (2) Internally and externally fired; and (3) Plain, Multitubular, and Tubulous. Large boilers are almost invariably horizontal, but small vertical boilers are often used. They are employed in Steam-cranes (q.v.) and other situations where great length would be an inconvenience, and otherwise very frequently when small powers are required, especially for temporary purposes. In Great Britain, where moderately good fuel is used, boilers with an internal furnace are generally preferred; but on the Continent the common brown coal is much inferior to our fuel, and a correspondingly larger quantity of it must be used to generate a given volume of steam. As the size of a furnace limits the fuel which it can burn, this frequently involves having a much larger grate than could be conveniently arranged inside the boiler, and on this and other accounts boilers are, on the Continent, more frequently externally fired than in this country. Under the head of 'plain' boilers come all ordinary cylindrical boilers, with or without internal furnaces, horizontal or vertical. They are the cheapest and simplest which can be made, and, if properly proportioned, possess a considerable evaporative efficiency. When it is necessary, however, to economise fuel, or space, or both, 'multitubular' boilers are frequently used. These derive their name from the fact that in them the flame and gases of combustion are made to pass through a great number of small tubes (surrounded by the water) on their way to the chimney. The steam-generating power of a boiler depends greatly on the extent of surface which it presents to the flame, and it is obvious that a great number of small tubes present a much larger surface than one large tube occupying the space of them all. Thus, with the same heating surface, a multitubular boiler will occupy much less space than a plain one, and at the same time the efficiency of its surface is found to be greater. It is, however, necessarily more expensive and more liable to get out of order. Tubulous boilers differ from multitubular boilers in not only containing tubes, but consisting of them, and having no large cylinders whatever. Their chief advantages are (a) their great strength, for it is easy to

make a metal tube strong enough to withstand pressures far higher than any at present in use; and (b) the peculiarity, that if any accident happens or explosion occurs, it will only be to one tube at a time, and not to an immense boiler shell (as with the common boiler), and its evil consequences will thus be greatly reduced. For this reason tubulous boilers are often called 'safety' boilers. It will be readily understood that there is no distinct line of demarcation between the three classes of which we have been speaking, but that, on account of the immense variety of boilers which have been designed and constructed, those of one class pass through gentle gradations into those of the next.

The commonest form of boiler for factories, &c. is that known as the 'Cornish,' and shown in fig. 1. It consists simply of a cylindrical shell, *a, a*, inclosing a much smaller cylinder, *f, f*, called a *flue*. The ends of the flue are open, but the space between it and the shell, which contains the water, is of course closed up and made steam-tight. The fire-grate, *d*, is in the interior of the flue, and at the end of it is a brick bridge, *c*, made so as to cause the flame to impinge on the upper side of the flue.

Fig. 1.

The boiler is set in brickwork; and the flame, passing out at the back end of the flue, is made to traverse the whole length of the boiler twice through brick flues before passing away to the chimney.

The Cornish boiler has often two internal flues or tubes, which is a much more advantageous construction than that shown in fig. 1. A Cornish boiler with two flues is known as a 'Lancashire' boiler. In the 'Galloway' boiler, a very excellent modification of the Cornish, which in outward appearance it exactly resembles, there are two furnaces, but these join together in one chamber just behind the bridges, and the gases are made to pass through a space considerably narrowed by side *pockets* projecting inwards in order that they may be well mixed. From this point to the back of the boiler there is just one flue, made oval in section, and crossed by a considerable number of vertical taper tubes, which form a direct communication between the water beneath and that above the flue. These tubes (called 'Galloway tubes') both promote circulation and strengthen the flue. Multitubular boilers of many kinds are used, both for stationary engines and other purposes, but the largest number of those constructed are certainly for steamers, and a common type of marine boiler is shown in fig. 2. The shell, *a, a*, is cylindrical, and contains one or more cylindrical furnaces; *c* is the fire-grate; *d*, a brick bridge; *e*, a combustion chamber or flame-box; *f*, the tubes through which the flame passes back to the front of the boiler; and *g*, the smoke-box at the base of the funnel, *h*. The line *k, k*, shows the ordinary level of the water in the boiler. On board ship it is of course an object to take up as little space as possible with the boiler and machinery, and at the same time to have boilers which shall use as little coal as possible, both because of the saving in cost, and because of the saving in the room taken up by coal. For all these reasons, marine boilers are invariably multitubular.

The varieties of vertical boilers are as numerous as those of horizontal. When dirty water, or water containing much insoluble sediment, has to be used (as e.g. in steam-cranes frequently), they are of the simplest construction, with nothing but an inner fire-box and an outer shell (both cylindrical), the space between them being filled with water all round and over the top of the fire-box. If clean water can be had, however, and it is desired to be at all economical of fuel, some kind of multitubular vertical boiler must be used, and of these probably the best is that known as the 'Field' boiler, and shown in fig. 3. The peculiarity of it consists in

Fig. 2.

Fig. 3.

the tubes, which are closed at the bottom and hang down from the top of the fire-box over the grate bars, containing inner tubes of much smaller diameter. The latter are intended to aid the circulation of the water, which passes down the inner tube and up again through the annular space around it, where, being most exposed to the action of the flame, it is hottest. Of the different varieties of tubulous boilers, those best known are perhaps the Babcock and Wilcox, the Root, and the Howard boilers. The great difficulty about all of them is the obtaining sufficiently free circulation for the water and the steam formed below its surface. But this difficulty seems to have been overcome in those first mentioned. Locomotive boilers are always multitubular, for much the same reasons as marine boilers. The boiler of a single locomotive often contains 1500 or 1800 square feet of heating surface, and occasionally as much as 2000 square feet.

The principal test of the efficiency of a boiler is the quantity of water (generally expressed either in pounds or gallons), which it will evaporate from and at a temperature of 212° F., with the consumption of one pound of coal. Of course, this varies very much with the quality of the fuel, but with good pit coal (not dross), a Cornish boiler often evaporates 6 to 8 lb. of water per lb. coal, and a multitubular boiler, such as fig. 2, about 10 or 11 lb. per lb. coal. Good Cornish or Lancashire boilers, however, often attain as great economy as those of any other type. The best rate of combustion on the grate varies with the construction of the boiler, from 10 to 18 or 20 lb. per square foot of grate surface per hour, and much more with forced draught, as in a locomotive.

Until very recently boilers were almost invariably made of wrought-iron plates riveted together. The parts most exposed to the action of the flame were made of the best quality of iron, and the other parts of inferior qualities, according to their position in reference to the flame. Now, however, for all first-class work, and work where high pressures are to be used, the common material for boiler construction is 'mild' steel made by the

open hearth process, and having a tenacity of about 28 tons per square inch. Copper is often used in the fire-boxes of locomotives, but seldom in any other description of boiler. Brass boiler tubes are sometimes seen, and on account of its better conducting qualities, brass is to be preferred to iron, but its dearthness prevents it superseding iron in the great majority of cases, and there are other drawbacks to its use.

Every boiler has, to render it complete and workable, a number of *fittings* or *mountings*, of which the following are the principal: A glass gauge to show the level of the water inside the boiler, and gauge-cocks for the same purpose; a gauge to show the pressure of the steam; a valve for admitting water; a cock at the bottom for emptying or 'blowing off'; a valve for the discharge of the steam; one or two safety-valves, weighted so that when the pressure of steam in the boiler reaches a certain height, they open and allow the steam to rush into the air; a door by which a man can get in to clean the boiler, &c.

In order to induce a current of air through the furnace so that a proper combustion may be maintained, stationary boilers are generally provided with a chimney of considerable height, and made of brick or sheet-iron, to which the products of combustion are conducted after they have left the boiler. In locomotive boilers, and in some other cases where a sufficiently tall chimney cannot be made use of, a very powerful current is made by the ejection of the waste steam through a blast-pipe with a contracted nozzle at the base of the chimney. To prevent loss of heat by radiation, and the consequent waste of fuel, boilers should always be covered, in all parts exposed to the atmosphere, with felt or some non-conducting composition.

For further details see also BOILING, GAS AND GASES, INJECTOR, SAFETY-VALVE, STEAM, and STEAM-ENGINE.

Boiling, Boiling-point. When heat is applied to a vessel containing a liquid (say water) at ordinary temperatures, the temperature of the liquid gradually rises. Vapour may be seen rising from its surface; and, after a time, bubbles of vapour form in the interior and move upwards, but disappear before they reach the surface. The disappearance of the bubbles is caused by the condensation of the contained vapour, and is accompanied by the so-called *singing* of the water. This noise is produced by the falling in of the walls of the bubbles when the vapour is condensed, and increases in intensity as the number of the bubbles increases. If heat be still applied, the temperature rises to such an amount that the bubbles no longer condense, but pass freely to the surface of the liquid. The liquid is then said to *boil*. When this occurs the temperature remains constant on the whole until all the water is boiled off. This temperature is called the *boiling-point*. It may be defined as the temperature at which vapour comes off *freely* from the surface of the liquid. Different liquids boil at different temperatures; and, for each liquid, this temperature increases with increase of the atmospheric pressure. The following numbers, extracted from Regnault's tables, show how the boiling-point of water is affected by pressure:

Temperature Centigrade.										
0°	10°	20°	30°	40°	50°	60°	70°	80°	90°	100°
Pressure in Atmospheres.										
0.006	0.012	0.023	0.042	0.072	0.121	0.196	0.306	0.466	0.691	1.000

Thus, if the pressure be 0.023 atmospheres, water will boil at 20° C. or 68° F. And if water at a temperature much below its ordinary boiling-point be placed under the receiver of an air-pump and the pressure be reduced, it may be made to boil.

It will give off vapour under these conditions until the pressure rises to that corresponding (as in the table above) to the given temperature. When this condition of equilibrium is reached, the vapour is said to be *saturated*. Thus we obtain another definition—the boiling-point of a liquid is the temperature at which its saturated vapour has a pressure equal to that to which its surface is subjected.

Abnormal boiling-points may be obtained artificially. Thus, if water be carefully heated in a very smooth and clean glass vessel, its temperature may be raised considerably above the ordinary point before it boils. But in this case the boiling takes place explosively when it does begin.

Since the atmospheric pressure depends upon the height above the earth's surface, the boiling-point of water varies with the height. This furnishes the principle of the hypsometric thermometer (see BAROMETER, and HEIGHTS, MEASUREMENT OF). Under the surface of a liquid the pressure increases with the depth. Hence the boiling-point increases with the depth. This explains the phenomena of the Geysers (q.v.). See also PAPPIN'S DIGESTER, and SPHEROIDAL STATE OF LIQUIDS.

Boiling, in Cookery. One important preliminary rule in boiling rests on the fact explained in the preceding article, that water cannot be heated in an open vessel, or in one with the ordinary fitting lid of a cooking-utensil, to a higher point than 212°. When a vessel, then, has once begun to boil, a stronger fire than is just sufficient to keep it boiling will only evaporate, or waste, the water in steam, but will not cook the food any faster. To boil a joint of meat successfully, it is necessary to place it in water already heated to the boiling-point, in order that the albuminous matters of the skin, &c. may be coagulated as speedily as possible. The coagulated albumen forms an impenetrable coating or varnish, as it were, thus preventing the soaking out of the nutritious juices of the meat. After this has been accomplished, the pot should be withdrawn from the fire, so as to allow the water only to simmer. The cooking goes on through the agency of the natural moisture of the flesh. Converted into vapour by the heat, a kind of steaming takes place within the piece of meat; it is, when skilfully done, cooked by its own steam.

The meat should be trimmed, washed, and dried before it is placed in the water. As it simmers, the water should be kept well skimmed, but with due remembrance of the fact that raising the lid of the vessel lowers the temperature of the water; and the preservation of an equal degree of heat throughout the operation is of the greatest importance. For fresh meat, 20 minutes is the allowance for each pound. The weather must also be considered: in frosty weather, or with very thick joints, extra 20 minutes should be given. Mutton loses in boiling, in 1 lb., 3½ oz.; beef, in 1 lb., 4 oz. Meat that has been salted and dried has its outer coat already sealed up; it requires, therefore, to be thoroughly washed, soaked for 2 hours in cold water, dried, and put to boil in cold water, gradually brought to the boiling-point, and kept simmering for a time proportioned to the size of the piece. Hams and tongues to be eaten cold, should be allowed to cool in the water in which they have been boiled. The following is a time-table for the cooking of these meats, reckoning from the time the water boils: A ham of 16 lb. takes 5 hours; a tongue of 16 lb., 2 to 4 hours; a pig's face of 16 lb., 2 hours; a piece of bacon of 4 lb., 2 hours.

Before boiling poultry or fish, it is advisable to rub the outside skin with a cut lemon. This insures a snowy-white appearance in the cooked food. Fish should be placed in cold water, in which a tablespoonful of salt and one of vinegar is mixed;

should be gradually brought to the boiling-point, and simmered carefully, lest the outer part should crack before the thick part is done. If on drawing up the fish-plate, a thin knife will easily divide the flesh from the bone in the thick parts, and if the eyes contract, and become like balls, the fish is sufficiently cooked. Drain by laying the plate across the kettle covered with the lid, and dish perfectly dry on the strainer, which should be covered with a napkin.

Vegetables require generally to be well washed, and placed in boiling water, in which is mixed a large spoonful of salt. To preserve the green colour they are best boiled in a pan without a cover. When they sink they are done. Green vegetables should be well picked, soaked in salt and water, drained and boiled in plenty of water, in a vessel without a lid. Cabbage requires two waters; spinach, very little, as it is full of moisture. Pease and beans should not soak, but be merely rinsed in a colander. Winter potatoes should soak for an hour or more; whether they should be placed in cold or boiling water depends on the description. A piece of soda the size of a small marble assists the boiling of pease and cabbage, if the water is very hard.

Frying is practically boiling in fat or oil, and when properly carried out, with a pan full of oil, is the preferable way of cooking fish and some vegetables.

Bois d'Arc (sometimes corrupted into BOBOCK), also Bow-wood, or Osage-orange (*Machura aurantiaca*), a tree belonging to the Artocarpaceæ, sub-order Moraceæ, is a native of the Southern United States. Its large beautiful orange-like fruits are scarcely eatable, but its spines make it useful as a hedge plant. Its wood is strong, and hard, and elastic, and hence was used by the Indians in the manufacture of their bows.

Bois-de-Boulogne. See BOULOGNE.

Boisé City, capital of the state of Idaho, U.S., stands in a fertile valley, near the Boise River, 520 miles N.E. of San Francisco. The public buildings include a United States assay office, gold being the principal article of export. A branch railway, 20 miles long, now connects the city with the Oregon Short Line Railroad. Pop. (1890) 2311.

Boisgobey, FORTUNE DU, a French novelist, was born in 1824 at Granville in Normandy, and died 26th February 1891. After several campaigns in Algeria as army-paymaster, he made his first appeal to the public in 1868, with a story in the pages of the *Petit Journal*. It was followed in quick succession by a crowd of sensational stories which soon gained a certain popularity even in England, spite of the exceptionally poor quality of the current translations. A close follower of Gaboriau, he has all his master's vigour and ingenuity, but lacks that sense of dramatic fitness and respect for verisimilitude which saved the original from the impossible absurdities of the imitations. But lovers of 'police-novels' are not exacting in literary workmanship, and Du Boisgobey's stories are at least always readable. Among the best are *L'Homme sans Nom* (1872), *Le Forçat Colonel* (1872), *L'As de Cœur* (1875), *Les Mystères de Nouveau Paris* (1876), *Le Crime de l'Opéra* (1880), and *Le Secret de Berthe* (1884). Some twenty of them have been translated.

Bois-le-Duc (Dutch, *'s Hertogenbosch*, 'Duke's Forest'), a city of the Netherlands, capital of North Brabant, is 28 miles SSE. of Utrecht by rail. It is a clean, well-built town, about 5 miles in circumference, intersected by canals, and was strongly fortified till 1876. Bois-le-Duc is the seat of a Catholic archbishop, and has a very fine cathedral (1312-1498), a town-hall, college, arsenal,

an academy of arts, a grammar-school, several hospitals, &c. Iron-founding, book-printing, the making of beer, spirits, woollens, cigars, jewelry, linen-thread, ribbons, and cutlery, are the principal industries. Bois-le-Duc was founded in 1184 by Godfrey III., Duke of Brabant, in a wood, hence its name. His son Henry strengthened the town with walls. The town was ineffectually besieged in 1601 and 1603, but surrendered to the Dutch in 1629. In 1794 it was taken by the French; and in 1814 retaken by the Prussians. Pop. (1869) 24,395; (1891) 27,594.

Boisserée, SULPIZ, was born at Cologne in 1783. Inspired with the idea of collecting the scattered specimens of early German art, he and his brother Melchior gathered together two hundred pictures in a gallery in Stuttgart. In 1827 the collection was sold to the king of Bavaria, and in 1836 transferred to the Munich *Pinakothek*. Sulpiz, who died in 1854, was author of *Geschichte des Doms von Köln* (1823-32) and other important works. See his Life by his widow (1862).

Boissonade, JEAN FRANÇOIS, Hellenist, born at Paris in 1774, became in 1809 titular, and three years later actual professor of Greek in the university of Paris; in 1813 member of the Academy of Inscriptions; and in 1828 professor of Greek Literature in the College of France. His more important works are *Philostrati Heroica* (1806); *Marini Vita Procli* (1814), *Tiberius Rhetor de Figuris* (1815), *Sylloge Poetarum Græcorum* (1823-26), *Babrii Fabule* (1844). He died at Passy, 8th September 1859.

Boissy d'Anglas, FRANÇOIS ANTOINE, COUNT, French statesman, born at St Jean Chambre, in Ardèche, in 1756, was for some time major-domo to the Count of Provence (Louis XVIII.), and a member of the States-general. During the Reign of Terror, fear of the 'Mountain' kept him quiet; but, yielding to the solicitations of Tallien and Barère, he joined the conspiracy against Robespierre. Two months after the execution of the tyrant, he was elected secretary of the Convention; and shortly after, a member of the Committee of Public Safety, in which capacity he displayed remarkable talent and discretion. As director of the supply of provisions for Paris, he was exposed more than once to popular hatred, but firmness and presence of mind preserved him. He was afterwards president of the Council of Five Hundred; was called into the Senate by Napoleon; and made a peer by Louis XVIII. Through all the changes of the times he maintained the principles with which he had commenced his career. He died in Paris, October 20, 1826. His chief writings are: *Recherches sur la Vie, les Écrits, et les Opinions de Malesherbes* (1819), and *Études Littéraires et Poétiques d'un Vieillard* (1826).

Boito, ARRIGO, Italian composer and poet, was born 24th February 1842, at Padua, and studied at the Milan Conservatorium. His first important work is the opera *Mcstofele*, produced without success in 1868, but which has steadily grown in popularity. It betrays the influence of Wagner. Other operas are *Ero e Leandro*, *Nerone*, *Odù all'Arte*. He wrote his own librettos, and has published several songs, lyrical dramas, and novels.

Boivin, MARIE, a French midwife, born in 1773, became a nun; but after the destruction of the nunnery at the Revolution, she devoted herself to midwifery. So distinguished was she as superintendent of the Maternité at Paris, that the king of Prussia conferred an order on her, and Marburg University the degree of M.D. She died in 1841.

Bojador, CAPE, a headland on the west coast of Africa, in 26° 7' N. lat., 14° 29' W. long. The Portuguese doubled this cape in 1432.

Bojano, an ancient Italian town with a cathedral, on the Biferno, 13 miles SW. of Campobasso. Pop. 3506.

Bokhara is the name given to the countries of Independent Tartary under the rule of the khan (or emir) of Bokhara. The most important part of it formed the ancient Sogdiana. The extent of the khanate of Bokhara has been constantly undergoing changes. Until recently it included the whole basin of the Zarafshan; but the Russians have now annexed Samarkand, and the lower basin of the river forms the essential part of the territory. The population of the present khanate has been estimated at from 1,000,000 to 2,500,000; its area is about 90,000 sq. m.

Only in the neighbourhood of the rivers is cultivation possible. The rest of the soil is composed of a stiff arid clay, interspersed with low sandhills. Bokhara has only three rivers of any importance—the Amu-Daria or Oxus, the Zarafshan, and the Karshi. Entering Bokhara at Koshtupa, the Amu flows through the country in a north-west direction to the Sea of Aral. Its banks in some parts are very fertile, especially in the neighbourhood of Balkh. The Zarafshan, which rises among the glaciers of the Alai range, issues out into the plain near Samarkand, and fertilises the district thence to the city of Bokhara. Before reaching the city, it sends out a northern branch, which, after a fertilising course of several miles, is absorbed in the sand. The southern branch, which passes Bokhara to the north, formerly extended to the Lake of Kara-köl, a salt-water sheet about 25 miles in circumference, which is connected with the Amu by irrigating canals; but of recent years its volume has been seriously lessened for purposes of irrigation, and now it, too, is lost among the ever-encroaching sands. Its upper banks, however, have been benefited by the process, and its valley is the richest as well as the most populous in Bokhara. The Karshi has a course of about 60 miles before it is also lost in the desert. Outlying provinces of Bokhara, separated by mountains, are Darwaz, Karategin, Hissar, and Kulab.

The climate is healthy, but subject to great extremes of heat and cold. The rains usually commence and end with February. Violent sandstorms are frequent, and occasion ophthalmia among the inhabitants. Minerals are scarce. The sands of the Oxus yield gold. Salt deposits are numerous. Alum and sulphur are found in the vicinity of Samarkand, and sal-ammoniac in the mountainous districts. The other products include rice and cotton, wheat, barley, beet-root, vegetables, hemp—only used in the preparation of *bhung*—silk, fruits in immense abundance, and tobacco. The camel's thorn, a plant that grows luxuriantly in Samarkand and Karshi, exudes a saccharine gum or manna, extensively used as sugar.

Sheep and goats form a great source of wealth. Camels are numerous and valuable; the horses are celebrated for their strength and endurance; and the breed of asses is excellent. Myriads of silk-worms are fed on the mulberry-trees that clothe the banks of every stream. The industry includes the manufacture of silk-stuffs, cotton-thread, shagreen, jewelry, cutlery, and firearms. Its geographical position secures Bokhara the transit-trade between Russia and the south of Asia; and the Transcaspiian Railway has probably increased the commercial prosperity of the country in proportion as it has lessened its prospect of maintaining its independence. The population, like that of the other khanates of Turkestan, consists chiefly of the aboriginal Tajiks of Persian, and of the dominant Uzbegs and

Turkomans of Turkish origin. Nomadic Arabs and Persian slaves are also numerous. The army numbers about 30,000, formerly badly armed, but since 1885 vigorously drilled by Russian officers, and armed with Berdan rifles.

Bokhara was conquered in the beginning of the 8th century by the Arabs, who were dispossessed of it in 1232 by Genghis Khan. It fell into the hands of Timur in 1403, and in 1505 was taken by the Uzbeks, its present masters. During the 18th century the khans were characterised by the worst abominations of eastern vice and fanaticism; and Bokhara lost its political pre-eminence among the khanates of Turkestan. The canals, which alone gave fertility to the country, were neglected; large areas were again overspread by the desert; and the population diminished. With the accession of the Khan Nasrullah (1826), a barbarous and incapable tyrant, the country became an object of rivalry to England and Russia, who sent envoys to cultivate his friendship (see BURNES); but he and his successor, Mozaffar-ed-din, treated both with equal insolence and contempt. After the capture of Tashkend by the Russians in 1865 (see TURKESTAN), a religious war was preached against the Russians, and the khan was compelled to oppose them. He was defeated at the battle of Irdjar, May 20, 1866; and in May 1868 Samarkand (q.v.), one of the most important cities of Bokhara, was taken. The command of the upper course of the Zarafshan, which fertilises the central part of the country, placed the khan entirely under the power of Russia. In July 1868 a peace was concluded by which Samarkand was ceded to the czar, and stipulations were entered into favourable to Russian trade. The treaty caused great dissatisfaction to the fanatic Mussulmans of Bokhara. They rose in rebellion, placing at their head Abd-ul-Melik Töre, the son and heir of the khan. The Russians aided the khan at his request; and in October the rebels were defeated near Karshi. The rebel prince sought refuge in Afghanistan. Shere Ali, the Afghan ruler, gave him a warm welcome, and would have invaded Bokhara had he not been restrained by Lord Mayo, the Indian viceroy, who told him that England could not encourage him in any attack on his neighbours. While Shere Ali was meditating this invasion, Abdurrahman, his nephew, who had married a daughter of the khan of Bokhara, endeavoured to obtain Russian aid in invading Afghan Turkestan with a Bokharian army. But, in this case, Russia opposed the enterprise (see AFGHANISTAN). During the invasion of Khiva in 1873 the khan efficiently assisted the Russians, and was rewarded by a large addition to his territory from the Khivan possessions on the right bank of the Oxus, under the treaty entered into between Russia and Khiva in July 1873. On the death of Mozaffar-ed-din in 1882 he was succeeded by Abd-ul-Ahad, his younger son, whose mental and physical weakness has rendered him anxious to secure the protection of Russia, and her assistance in governing his country. Since his accession, a Russian political agent has been appointed, and a Russian bank established in Bokhara, and everything points to the early absorption of the country into Russian Turkestan, in which the annexation of Merv in 1884 has practically inclosed it. See Vambéry's *History of Bokhara* (1873), and Lansdell's *Russian Central Asia* (1885).

Bokhara, capital of the above khanate, is situated on a plain a few miles from the Zarafshan, in 39° 48' N. lat., 64° 26' E. long., in the midst of trees and gardens. It is between 8 and 9 miles in circumference, and surrounded by embattled mud walls about 24 feet high, and pierced by eleven gates. The houses, which are small and ill lighted,

are built of sun-burned bricks on a wooden framework; and the roofs of all are flat. The streets are ill paved and very narrow, the widest barely sufficing for the passage of a loaded camel. The palace of the khan occupies an eminence of between 200 and 300 feet in height in the centre of the city. It is surrounded by a brick wall 60 or 70 feet high. The mosques, which are said (fabulously) to be 365 in number, necessarily form one of the greatest features of Bokhara, which is the centre of religious life in Central Asia. The most imposing one occupies a square of 300 feet, and has a cupola 100 feet high, ornamented with blue tiles. Attached to it is a tower of about twice the height, built by Timur, from which criminals are hurled. The city has long been celebrated as a seat of learning, and contains, in addition to a vast number of schools, about 80 colleges, which are attended, it is stated, by some 5000 students; among these, in past times, have been pupils from India, Cashmere, and Chinese Turkestan. A canal intersects the city, but the water, which becomes very scarce in summer, is at all times a source of disease from the filthy state in which it is kept. Bokhara is still the most important commercial town in Central Asia, although the gradual drying up of the Zarafshan, through the Russian irrigation-works at Samarkand, has lessened the population by about a half. Silks, woollens, and swords are manufactured, and large slave-markets are held; but the most striking feature of the town is its numerous bazaars, gorged with the richest wares of Europe and of Asia. Bokhara was in 1888 connected by the Transcaspiian Railway with Merv, and so with the Caspian ports. The pop. is estimated at 70,000. See TURKESTAN.

Bokhara Clover. See MELILOT.

Bolan' Pass, a narrow, precipitous gorge, ascending in a generally north-west direction from a point 5 miles NW. of Dohur to the broad plateau of Dasht-i-Bidaulat, in Beluchistan, and lying pretty directly between Sind and Kandahar. Its entrance and its outlet are respectively 800 and 5800 feet above the level of the sea. The total ascent, therefore, is about 5000 feet, which, on a length of barely 55 miles, gives an average of fully 90 feet to the mile. Along the bottom of the pass descends a torrent, now repeatedly bridged by a good military road; and in 1885-86 a railway, 56 miles in length, was laid for military purposes. Over part of it there are three rails, the central one being toothed to catch a cog-wheel on the engine. The route, without being impracticable, is highly defensible in a military point of view, and is commanded by the fortress at Quetta, now British. It is bounded throughout by eminences which sometimes attain a height of 800 feet; and yet, in 1839, a British column of artillery accomplished the whole distance in six days. From the northern outlet there is no fall, and a good road runs to Quetta, 25 miles away.

Bolas (Span., 'balls'), missiles used by the natives and *gauchos* of southern South America, consisting of two heavy balls, generally of stone covered with leather, connected by a plaited thong 6 to 8 feet long. One bola is held in the right hand, while the other is swung rapidly round the head, at the full extent of the thong, and both are discharged at the animal to be captured, so as to wind round its feet, and bring it to the ground. In another form of bolas, there are three balls, not of the same size, connected at the common centre by three short thongs or ropes.

Bolbec, a busy town in the French department of Seine-Inferieure, 19 miles ENE. of Havre by rail. A stream of the same name supplies water-power for several mills, where woollens,

linen, cotton, and chemicals are manufactured. Pop. (1872) 10,009; (1891) 11,125.

Boldrewood. ROLF, is the pseudonym of Thomas Alexander Browne, author of *Robbery Under Arms* (1888), *A Modern Buccaneer* (1894), and other tales of adventure in Australia. Born in England in 1827, he was taken to Australia in 1830 by his father, Captain Sylvester John Browne, one of the founders of Melbourne; and there, after a good education and a varied experience in stock-farming and other vocations, he became a police magistrate and goldfields commissioner. He contributed to the *Cornhill Magazine* in 1865, and has written in other serials.

Bole is an earthy mineral resembling clay in structure, and consisting essentially of silica, alumina, red oxide of iron, and water, which occurs in nests and veins in basalt and other trap rocks. It feels more or less greasy when placed between the fingers; is of different colours—yellow, red, brown, and black; has a dull, resinous lustre, but a shining streak; and is readily friable and not plastic. Armenian bole has a red tint, and is used for colouring tooth-powders and false anachovies. Lemnian Earth (containing a large percentage of silica) is the bole from the island of Lemnos; it is red in colour, and was at one time prescribed as a tonic and astringent medicine—no doubt from the large percentage of oxide of iron present. The boles which are employed in veterinary practice in Europe are generally made from Armenian bole. The savage tribes in South America eat bole to allay the pangs of hunger. When bole is calcined, it becomes hard; and when afterwards levigated, a coarse red kind is used as a pigment. French bole is pale red; Bohemian bole, reddish yellow; Silesian bole, pale yellow; and Blois bole is yellow.

Bole'ro, a Spanish national dance, invented in 1780 by the dancer Sebastian Zerezo. It is danced in moderately quick three-quarter time by two persons to the accompaniment of the castanets and the guitar. The name is also applied to the air to which it is danced. Like the *fandango* it is said to be originally a refinement of an African dance still performed by the Congos under the name of *chika*.

Boletus, a genus of Hymenomycete Fungi (q.v.). The older botanists included in it the numerous species now forming the genus *Polyporus* (see AMADOU, DRY ROT, and POLYPORUS) and other genera; but even as now restricted, it includes about one hundred European species. Most of the species resemble the common mushroom and other species of *Agaricus* in general form, but are distinguishable at a glance by the pore-like surface occupying the place of gills. Unlike *Polyporus*, the whole spore-bearing tissue (hymenium) is easily detached. Some of the species

Boletus edulis.

are edible. *B. edulis* is much used in France, also in Germany, Hungary, Russia, &c. It is the *ceps ordinaire* of the French markets. It grows on the ground in thin woods of oak, chestnut, or beech, and sometimes in mountainous districts, in places covered with moss, heath, or grass. In moist warm summers it sometimes appears in prodigious quantities. It has also been partially cultivated by inclosing a portion of a wood, and watering the ground with water in which the plant has been steeped, thus, in fact, sowing its minute

spores. In Britain it is comparatively rare. The cap is smooth, 6 or 7 inches across, with a thick margin, varying in colour from light brown to brownish black; the tubes at first white, then yellow, and finally yellowish green; the stem thick and solid, beautifully reticulated. The tubes are removed along with the skin and stem, and only the flesh of the cap is eaten, which is firm, white, delicate, of agreeable smell, and is prepared like the common mushroom, dried to flavour sauces, ragouts, &c., or eaten raw with salt and pepper. It is wholesome and nutritious, and is certainly to be reckoned one of the very best of the edible fungi. —*B. scaber* is another edible British species, but much inferior. —*B. aeneus* is the *ceps noir* of the French markets, and *B. aurantiacus* is the *girolle rouge* or *roussille*. They are used like *B. edulis*. Forms of which the flesh turns blue when broken and exposed to the air, should be avoided as probably poisonous.

Boleyn. ANNE, second wife of Henry VIII., was born in 1507, and was the daughter of Sir Thomas Boleyn, afterwards Viscount Rochford and Earl of Wiltshire, by Elizabeth Howard, daughter of the Duke of Norfolk. She spent some three years (1519–21) at the court of France, and soon after her return to England was wooed by Lord Henry Percy, the heir to the earldom of Northumberland, and by King Henry himself, who in the April of 1522 began to shower wealth and honours on her father, and who ere this had dishonoured her sister Mary. Not till the king's divorce from Catharine of Aragon was set afoot (in May 1527) does Anne seem to have favoured his addresses; but long before Cranmer pronounced the divorce (23d May 1533) she was Henry's mistress, and in the preceding January they had been secretly married. She was crowned with great splendour in Westminster Hall on Whitsunday; but within three months Henry bade her 'shut her eyes to his unfaithfulness, as her betters had done, for he could abase yet more than he had raised her.' His cooling passion was not revived by the birth, in September 1533, of a princess, the famous Elizabeth, still less by that of a still-born son, on 29th January 1536, barely three weeks after the death of Queen Catharine. On next May-day the king rode off abruptly from a tournament held at Greenwich, leaving the queen behind, and on the morrow she was arrested and brought to the Tower. The story runs that his jealousy was kindled by her dropping a handkerchief to one of her lovers in the lists below; anyhow, a week before, a special commission had been secretly engaged in examining into charges of Anne's adultery with her own brother, Lord Rochford, with Sir Francis Weston, Henry Norris, and William Brereton, gentlemen of the privy chamber, and with Mark Smeaton, a musician. Only Smeaton made any confession; but on the 12th the four commoners, on the 15th Anne and her brother, were tried and convicted of high treason. Her own father and her uncle, the Duke of Norfolk, were instrumental in her death, the latter presiding over her judges, the twenty-six peers, and pronouncing her doom. No vestige of the evidence remains. On the 17th Smeaton was hanged, and the other four beheaded; and two days later, upon Tower Green, Anne submitted her slim neck to the headsman's axe. Henry the next day married Jane Seymour. That Anne was guilty of adultery with Henry is certain; that she was guilty of incest with her brother, or even of adultery with her other alleged paramours, remains at least not proven. The character of this 'mother of the English Reformation' was not saintly; but she probably was not the Jezebel that Saunders, the Jesuit, would have us believe.

According to him, she was even in person ugly, misshapen, monstrous; whereas we know that she was a comely brunette, her only defect a supplemental nail. See Hepworth Dixon's *History of Two Queens* (1874); Paul Friedmann's *Anne Boleyn* (2 vols. Lond. 1885); and works cited under HENRY VIII.

Bolgary, a village in the Russian government of Kazan, near the Volga, with about 150 houses. It occupies the site of Bolgar, capital of the old Bulgarian kingdom, remains of which, in the form of ruined buildings, walls, and minarets, yet attest its former state.

Bolgrad, a town in the Russian province of Bessarabia, 28 miles NW. of Ismail, at the head of Lake Yapuch, a feeder of the Danube. It is well built, and has some trade and manufactures of soap, candles, pottery, &c. Pop. 8179, many of them Bulgarian immigrants.

Boli, an ancient town of Asia Minor, on the left bank of the river Boli, 136 miles E. by S. of Constantinople. Pop. 5000.

Bolide is a name given to a large meteor which explodes and falls in aerolites; a fire-ball. See METEORS.

Bolingbroke, HENRY ST JOHN, VISCOUNT, one of the most gifted of English statesmen and orators, was born at Battersea, on October 1, 1678. He belonged to a good family, and was educated at Eton. The statement which his various biographers have repeated of his having matriculated at Christ College, Oxford, has been disproved by recent research. After travelling on the Continent, he entered parliament in 1701 as member for Wootton Bassett. There were at the time three political parties, the Jacobites, the Tories, and the Whigs. Bolingbroke joined the Tories, and gained immediate distinction by his vigorous and polished eloquence. From 1704 to 1708 he was Secretary for War in the Godolphin ministry; in 1710 he became Foreign Secretary, and shared the leadership of the party with Harley. He was called to the House of Lords in 1712, and in 1713 he negotiated the Peace of Utrecht. This was the one act of his political career which was of benefit to his country. It did not, however, bring him popularity as a statesman, and he estranged his followers by his morbid love of secret scheming, his desire to do everything alone and in the dark. After plotting successfully for Harley's downfall, he set to work to form a Jacobite ministry in July 1714. A week afterwards his designs were shattered by the death of Queen Anne. George I. came to the throne, and Bolingbroke, who had intrigued on behalf of the Stuart cause, fled to France. He was attainted in 1715, and acted for some time as Secretary of State to the Pretender. While living abroad he wrote his *Reflections on Exile*, and addressed a letter to Sir William Wyndham, in vindication of his political career. His first wife, a daughter of Sir Henry Wincheomb, having died in 1718, he married in 1720 the rich widow of the Marquis de Vilette. By the shrewd use which he made of this lady's wealth, he obtained permission to return to England, where he was not allowed, however, to sit in the House of Lords. He then settled at Dawley, near Uxbridge, and became the associate of Pope, Swift, and other men of letters. It was his ambition to be ranked among philosophers, but the ethical studies in which he engaged could not wean his attention from politics. He intrigued in London for an office which he never obtained, and attacked Walpole with the utmost bitterness in a series of letters which appeared in the *Craftsman*, and were reprinted as *A Dissertation on Parties*. Disappointed in his hopes of readmission to political life, he returned to France, where he

remained from 1735 to 1742. During these years he produced *A Letter on the True Use of Retirement*, and his most important contribution to literature—the *Letters on the Study of History*. The precepts which he laid down for the historian's guidance were indorsed by Voltaire and carried into practice by Macaulay. Bolingbroke's last years were spent at Battersea, where he wrote his *Letters on the Spirit of Patriotism*, and his *Idea of a Patriot King*. He died, after a long illness, on the 12th December 1751. 'The Alcibiades of his time,' Bolingbroke is one of the most interesting and brilliant figures in English history. He was idolised by his contemporaries for the grace of his person, the charm of his manner, and the splendour of his talents. An admirable speaker and writer, he was not a great statesman—hardly a skilful party leader. He was the arch-intriguer of his time; as a politician he was thoroughly selfish and insincere. In his writings he preached a double morality; while he considered Christianity a fable, he held that a statesman ought to profess the doctrines of the Church of England. His philosophy is sensational; and as a cynical critic of revealed religion, he was accounted one of the notable English deists. His works, philosophical and political, are written in an oratorical strain. They are models of polished, pointed, declamatory prose. They deserve to be studied if only for the merit of the style; their matter is of less interest, but their wit retains its edge, and their eloquence its glow. Bolingbroke's collected works were published by David Mallet in 1753-54. See Brosch, *Lord Bolingbroke und die Whigs und Tories seiner Zeit* (1883), and *Bolingbroke, a Historical Study*, by John Churton Collins (1886).

Bolivar, the name of several states and territories of South America.—(1) A state of Colombia, lying W. of the Magdalena. Area, 21,345 sq. m.; pop. officially estimated at very nearly 350,000. The surface is mostly low and well watered, with many swamps; the climate in some parts is hot and unhealthy. Capital, Cartagena; chief port, Barranquilla.—(2) The largest of the United States of Venezuela, extending from Colombia to the Atlantic, and watered by the Orinoco and its tributaries. Area, 88,383 sq. m.; pop. 58,560, in which are included some sparsely settled districts around. The state is frequently called Guayana; for its capital, Ciudad Bolivar, see ANGOSTURA.—(3) A province of the republic of Ecuador; pop. 63,000.—(4) An agricultural settlement of Venezuela, 30 miles NE. of Caracas, founded in 1874 to receive immigrants.—(5) One of the new territories of Buenos Ayres, 170 miles SW. of the capital. Area, 2070 sq. m.; pop. 2055.

Bolivar, SIMON (named *El Libertador* for having rescued South America from the Spanish yoke), was born in Caracas, in what is now Venezuela, July 24, 1783, and was descended from a noble and wealthy family. He studied law at Madrid, and visited several other capitals, witnessing in Paris the closing scenes of the Revolution. In 1801 he returned to Caracas, but on the death of his young wife he came to Europe again in 1804, and in 1809 visited the United States, from which he returned with the determination to free his country from foreign despotism. Arriving in Venezuela, he at once associated himself with the patriots there; and after the insurrection at Caracas in 1810, he was sent to London with a view to interest the British cabinet in their aims. The British government, however, declaring its neutrality, Bolivar speedily returned. On the declaration of independence by Venezuela on July 5, 1811, war was commenced by the Spaniards, and

Bolívar fought under General Miranda in several successful engagements. The royalists having again obtained possession of Venezuela, Bolívar had to flee to Curaçao; but in September 1812 he joined the insurgents in New Granada, and driving the Spaniards back beyond the Magdalena, recrossed the frontier with a force of 500 men, and proclaimed a war to the death. His army increased with each victory; and on August 4, 1813, he entered Caracas as a conqueror, and proclaimed himself dictator of western Venezuela. Fortune soon deserted the patriots, however; in June 1814 they were routed at Cura, and 1500 slain. Bolívar was compelled to retire to Cartagena, and, after some further service in New Granada, to Kingston in Jamaica, where an assassin, hired by the Spaniards, tracked his steps, but by mistake murdered his secretary. Having visited Hayti, and assembled there the insurgent refugees (1816), Bolívar twice landed in Venezuela; he was finally compelled to flee to Barcelona, and there formed a provisional government. The following two years were marked by a series of conflicts in which the scattered parties of patriots were most frequently beaten. In 1819 a congress was opened at Angostura, and Bolívar was confirmed in the supreme power. Having conducted his army, of which the British legion formed a third, over the almost impassable Cordilleras to New Granada, he achieved the victories of Tinja and Boyaca, and soon afterwards declared New Granada united with Venezuela as a republic, under the name of Colombia. Nevertheless, although Bolívar had a force at least twice as large as Morillo, the dissensions of the patriots prevented any concerted action, and it was only in June 1821 that the victory of Carabobo virtually ended the war in Venezuela; while it was not till July 1824 that the royalist troops were finally driven out of the country. The constitution of Colombia was adopted on August 30, 1821, and Bolívar was chosen president.

In 1822 Bolívar added Ecuador to the republic, and was summoned to help the Peruvians. Bolívar was named dictator of Peru, from which possession also the Spaniards were driven, after more than two years' fighting. In 1825 Bolívar visited Upper Peru, the name of which was changed in his honour to Bolivia. A constitution prepared by him in 1826, at the request of the Bolivians, excited dissatisfaction and even alarm, chiefly on account of its proposal to intrust the executive power to a president for life, without responsibility, and with power to name his successor. In September he intrusted the government of Peru to a council appointed by himself, and returned to quell a disturbance in Venezuela. His personal influence prevailed, and he was re-elected president, in spite of his expressed unwillingness; but meantime, in Peru his famous code had been renounced, and the Colombian troops had been expelled from Bolivia. His assumption of supreme power in August 1828 roused the apprehension of the republicans; the dread of a second Napoleon led to a conspiracy against his life; and in November 1829 Venezuela separated itself from Colombia. In consequence, Bolívar laid down his authority in April 1830, when the congress of Bogotá, now largely made up of his enemies, voted him a pension of 3000 dollars, on condition of his residing abroad. He died at San Pedro, near Santa Marta, 17th December 1830. Bolívar has been described as the Washington of South America. The difficulties of the war of liberation compelled him to assume a dictator's power, but there is no proof that he was ever insincere in his devotion to liberty; and in the service of his country he not only gained no wealth, but freely spent his own large fortune. In

1842 his remains were removed with great pomp to Caracas, where a monument has been erected to his memory; statues have been raised to him at Bogotá, Lima, and New York; and the Liberator's centenary was celebrated at Caracas with great enthusiasm in 1883, when sixteen foreign states were represented at the various functions, which extended over forty days.

Bolivia, a republican state on the west side of South America, formed in 1825, and deriving its name from Bolívar. Formerly called Upper Peru, it was till 1825 part of the viceroyalty of Buenos Ayres. It extends between 8° and 23° S. lat., and 57° 30' and 73° W. long., and is inclosed by Peru, Brazil, Paraguay, the Argentine Republic, and Chili. A portion of the Argentine frontier has been for some time undetermined. Its coast provinces Bolivia lost to Chili in consequence of the war between Bolivia and Peru with Chili in 1879-83. The area of the republic—842,729 sq. m. in 1869—was reduced by the disastrous war on the side of Peru against Chili to 536,000 sq. m. (more than four times the size of the United Kingdom). The population is probably under 1,500,000, though some estimates give 2,300,000, of whom rather more than half are native Indians.

Surface and Hydrography.—Prior to the treaty of 1884, Bolivia contained the loftiest and most mountainous district of America; but as since then her western frontier has been bounded by the Andes, this claim would now be only partly true. The Peruvian frontier is, however, unchanged; and the lofty plateau of Oruro, with an average height of 13,000 feet, and about 150 miles broad, is inclosed between the Andes proper and the Cordillera Real, to the east. There are also intermediate ranges and isolated groups; and the volcanoes, confined to the western region, include Sahama, Illampu, and Ilimani, all over 21,000 feet high. The great plateau falls into two parts, of which the northern is the more inhabited, the Lake of Titicaca and the many well-watered valleys around making the district not so unproductive as its great elevation would otherwise render it. This lake, with an area of more than 3200 sq. m., and a depth of 120 fathoms, incloses several islands, the largest of which was the home of the founders of the empire of the Incas. The Rio Desaguadero, with a course of 160 miles, connects it with the salt lake and swamps of Aullagas or Paria, scarcely one-third the size of Titicaca; and somewhat to the west lies the Laguna de Coiposa, a basin covered, in the dry season, with a thick crust of salt. The southern and lower tableland is chiefly a desert, where the mountain streams either sink into the sand, or flood, in the rainy season, what are salt pampas throughout the rest of the year. The Cordillera Real system descends abruptly, on the north, to the plain of the Amazon; but its eastern edge is a series of terraces, sinking gently to the plains of eastern Bolivia, which in the north belong to the Amazon basin, and in the south to the pampas of the Plata. This eastern region is a cradle of both rivers, gathering for the latter the Pilcomayo, with its tributary streams, which flows through the Gran Chaco to feed the Paraguay, and for the former the Guapey or Rio Grande, which afterwards becomes the Mamoré, and unites with the Beni (q.v.) to form the Madeira. See AMERICA, ANDES.

Climate and Vegetation.—Although situated entirely within the tropics, Bolivia, from its varied elevation, possesses a wide range of climate and productions. The regions with an elevation of over 11,000 feet are called *punas*, while the *puna brava* is the region of snow and ice above 12,500 feet. This division includes the whole tableland of Oruro and the loftier mountain peaks. The

climate is cold and dry, but generally healthy, in spite of the cutting winds, the extreme rarity of the atmosphere, and the occasional days of great heat, followed by bitterly cold nights. Vegetation is scanty, and cultivation mainly confined to potatoes, barley, and coarse grasses, which maintain the animals of this zone. Here, and in the higher parts of the next region, the dry and rainy seasons are distinguished, the latter extending from November to March. The *cabezeras de valles* are the heads of valleys descending to the lowlands, in the eastern terraces, between 9500 and 11,000 feet; the deeper valleys, between 5000 and 9500 feet, are called *medio yungas*. The former have a temperate climate, and wheat and maize are produced in large quantities; in the latter, tropical fruits begin to flourish. East of the inner Cordillera lie the *yungas*, or plains under the 5000 feet limit. This district, with its numerous streams, its luxuriant tropical vegetation, its rich forests of valuable trees in the north, and its immense open savannahs in the south, surpasses most countries of South America in fertility and resources. Coffee, rice, cacao, coca, pine-apples, bananas, tobacco, cotton, and the valuable cinchona are cultivated; and among other important plants are the copal and caoutchouc trees. The rainfall here is uncertain. Intermittent fevers are confined to the northern plains, where the overflowing rivers and rank vegetation are added to a hot and moist atmosphere.

Animals.—In the *panas* are found the guanaco, llama, alpaca, and vicuña—animals almost as independent of water as the camel—and the chinchilla; in the east, jaguars, tapirs, and other wild animals common to Brazil. The first three are prized for their skins, and are also largely employed as beasts of burden; the vicuña yields a long, soft wool; and the chinchilla skins also form a valuable article of commerce. Large numbers of sheep are herded in the highlands, and of cattle in the plains.

Minerals.—While agriculture and stock-raising have never received proper attention in Bolivia, the development of its mineral resources has always been the most important industry of the country; for its great yields of gold, silver, copper, and tin ores have for centuries given a large profit, in spite of the excessive cost of transport. The mines of Potosi, which have been worked since 1545, are estimated to have produced, up to the present, over £600,000,000 sterling of silver. Since the war of independence (1809-25), the industry has been practically uninterrupted, and specially fostered by favourable fiscal regulations. The want of good roads or accessible seaports, and a lack of better fuel than llama-dung or moss, have seriously impeded the work; but the approach of railways, and the discovery of coal in several provinces, promise to remove these checks. Consequently, a great revival in mining enterprise has been noticeable since 1883, many abandoned mines having been reopened. Potosi still produces about 2,800,000 ounces; Oruro yields as much; and the richest mine, Huanchaca, to the south-west of Potosi, more than twice that amount. The product of all the silver-mines is estimated at over £3,000,000 annually. Lead and quicksilver are frequently found along with the silver. Gold-mining has been abandoned, except by the Indians, who carry it on in a primitive way; but the metal is still washed in grains from the rivers of the eastern slope and foot-hills of the Cordillera Real. The rich copper-mines have recently been less worked, chiefly owing to difficulties of transportation.

Commerce, Communication, &c.—From the landlocked position of the republic, its foreign trade labours under heavy disadvantages, which the nature of its great rivers, rendered unnavigable by

rapids, has increased. An uninterrupted route was reported to have been discovered in 1887, by the Acquiri, Purns, and Amazon; but as this would connect Brazil only with the extreme north of Bolivia, beyond the Madre de Dios, its practical value is doubtful. More is to be hoped for from the railways, which are now steadily approaching the country from the south. Prior to the Chilean war, its favourite marts were the Peruvian port of Arica and its own Cobija, in Atacama. But both Argentine and Brazil having granted gratuitous egress through their ports, a great part of Bolivia's productions have since been drained through these countries, chiefly the former. In order to restore the trade to the Pacific, a railway has been made from the now Chilean port of Antofagasta, which forks at Uyuni, in Bolivia, one branch going to Oruro, the other to the Huanchaca mines. The Paraguayan government has granted a concession for a line by the Pilcomayo to Bolivia and Peru; and concessions have been granted by the Argentine Republic for parallel routes through the Gran Chaco, and another road approached Jujuy. A railway to connect Potosi with the Argentine frontier is also projected; meanwhile, the bulk of the trade of La Paz is still by rail to Aygacha (50 miles), and by steamer across Lake Titicaca to Puno, in Peru, and thence by rail to Mollendo. A railway from La Paz to connect with the Mollendo-Puno one is proposed. Concessions granted in 1868, for opening up the Mamoré and Madeira to navigation, produced no result, although the Brazilian government was reported to be willing to render the Madeira navigable for 400 miles from its junction with the Amazon, and to levy no transit dues. There are about 400 miles of telegraph lines, mostly connecting with the Argentine system. Recent customs returns there are none, but a careful estimate would give the annual value of exports at slightly over £2,000,000, and of imports at about £1,400,000. Two-thirds of the exports consist of silver. In one year there have been shipped to various countries through Arica 550 tons of copper, 800 tons of copper ore, 500 tons of tin, and 600 tons of silver in bars and ore. The exports to Great Britain amount to about £200,000; the imports from thence amount to £50,000 or £60,000, being chiefly iron, cotton, woollen, and manufactured goods. A considerable trade is carried on also with Germany and France, but there is no direct commerce with the United States. Bolivian manufactures are very backward, firearms and brandy alone showing any recent advance; but the coca and cinchona plantations are attracting a great deal of attention and capital. In 1885 there were over 5,000,000 cinchona-trees, yielding 200,000 lb. of bark; and the coca-leaf is in large demand, both for home consumption and for export.

Population.—The population of Bolivia is a mixture of various races, half-caste Spaniards and Indians, with some descendants of negro slaves formerly brought from Africa. About a third of the people live in the towns, the remainder in hamlets or in the *Campaña*. All the Indians are divided into three classes—civilised, semi-civilised, and wild. To the first belong the Quichua and Aymará Indians, chiefly inhabiting the highlands of the west. The former are direct descendants of the Incas, whose language and manners they preserve, and form 50 per cent. of the pure native population; the Aymará are a kindred race, about half as numerous. They are devout Catholics, mild in character, apathetic, with more endurance than energy, and are mostly *arrieros*, or drivers of llama-trains, or engaged in llama and sheep raising and rude agriculture. The second division is filled by the Chiquito and Moxos Indians of the great north-eastern llanos, who retain part of the

civilisation introduced by the Jesuits in the 17th century; while the several tribes of nomadic Indians inhabiting the eastern plains belong to the third. These last are quite wild, but although more or less maliciously disposed towards the Spanish race, their dislike seldom finds expression in overt acts; and in consequence, travel in Bolivia is comparatively safe. The half-bred population is about a third as numerous as the pure Indian; the *cholos*, a Spanish and Indian mixture, form the most important element, and to them Bolivia largely owes her independence. The religion of the country is Roman Catholic, but others are tolerated; there are four dioceses, including an archbishopric of La Plata. Education is extremely backward. Of the four universities, three are for law students alone; and in 1884 only 5 per cent. of the children of school age attended the schools. Consequently, literature is at a low ebb in Bolivia, and its few newspapers have the least weight of any in South America.

Government, &c.—According to the constitution, the executive is vested in a president, with two vice-presidents, and a ministry divided into five departments; while the legislature consists of a congress of two chambers, the Senate and the House of Representatives, both elected by universal suffrage. In practice, the law requiring the election of the president every four years has seldom been observed; and since the presidency of General Santa Cruz (from May 1828 to January 1839), the history of Bolivia is a record of military insurrections, the supreme power having been almost invariably seized by successful commanders. There have been no returns of the actual revenue and expenditure for several years; in the budget for 1894-95 the receipts were stated at £600,000, the expenditure at over £700,000. The public debt is set down at about £6,000,000, including a 'forced war loan' to equip troops against Chili, and a foreign debt of £1,700,000, contracted in England in 1872 to open up the Madeira route. The best authorities, however, returned the total debt in 1894 at £2,500,000, of which the foreign debt amounted to £1,500,000; though a general uncertainty, in which the Bolivian government seems to share, apparently exists as to the precise amount. Some two-thirds of the annual revenue is expended on the standing army, which consists of about 1400 men, commanded by 8 generals and 1013 other officers. Bolivia is divided into fourteen provinces. The seat of the executive government, formerly La Paz, was transferred in 1869 to Oruro, and is now at Sucre. The chief towns are La Paz (26,000), Cochabamba (14,705), Chuquisaca or Sucre (12,000), and Potosi (11,000).

Bolivia declared its independence 6th August 1825, and took the name of Bolivia on the 11th of that month. The first congress met in the following year, and adopted a constitution prepared by Bolívar (q.v.), which has since, however, been greatly modified. The subsequent history of the state has been largely a series of restless and purposeless revolutions. Slavery was abolished in 1836. In 1879 a war broke out between Chili and Bolivia allied with Peru, of which the issue was disastrous to the allies. The terms of peace were severe, and stripped Bolivia of her seaboard district, with its stores of nitre and guano, besides demanding a heavy war indemnity.

Bolkhov, a cathedral city of Russia, on the river Nugra, 37 miles N. of Orel. It manufactures leather, gloves, hosiery, and soap, and has an active trade in tallow, hemp, oil, fruit, and vegetables. Pop. (1893) 26,395.

Boll, a measure of capacity for grain, &c., used in Scotland and the North of England. In Scot-

land it is usually equivalent to 6 imperial bushels, but in England it varies from that to 2 bushels—the 'new boll.' It is also a measure of weight, containing, for flour, 10 stone (= 140 lb.). The word is pronounced *bow* in modern Scotch; being entirely a northern word, it may be distinct from the English *bolc*, and be rather an old Norse word—the Scandinavian equivalent of the old English *bolle*, modern *bowl*. See a table of its local values in *Old Country and Farming Words* (English Dialect Society, 1880).

Bollandists, an association or succession of Jesuits by whom the *Acta Sanctorum* (q.v.), or Lives of the Saints of the Christian Church, were collected and published (1643–1794). They received their name from JOHN BOLLAND, born in the Netherlands 1596, died 1665, who edited the first 5 vols., containing the month of January in 2 vols. published in 1643, and the month of February in 3 vols. published in 1658. The vast undertaking had been projected by a Flemish Jesuit, Heribert Rosweyde, and on his death in 1629 his collections were intrusted to Bolland, who established himself in Antwerp, opened a correspondence all over Europe, and associated young men of his order with himself in the work. The suppression of the Jesuit order in 1773 caused the removal of the Bollandist Society to the monastery of Coudenberg, in Brussels, till the persecutions under Joseph II. brought about its dissolution. In 1789 the abbey of Tongerlo in Brabant took up the colossal task of carrying on the *Acta Sanctorum*; but scarcely had the 53d volume appeared in May 1794, bringing the calendar down to October 6, when the French occupation, and their destruction of the MS. collections, put an end to the work. In 1837 a new Bollandist association of Jesuits was formed under the patronage of the Belgian government, which set aside a yearly sum of 6000 francs for this object, and in 1845 the 54th volume appeared. Upwards of 60 volumes have now appeared (the part published in December 1887 carrying the work into November); and there is thus a prospect of the completion of this vast work, of which Gibbon has truly said, that 'through the medium of fable and superstition it communicates much historical and philosophical instruction.' A new edition, in 61 vols., was published in Paris (1863–67), and since 1882 supplements, with facsimiles of the more valuable MSS., have appeared at Paris and Brussels, under the title *Analeccta Bollandiana*. See SAINT.

Bologna, one of the most ancient cities of Italy, beautifully situated on a fertile plain at the foot of the lower slopes of the Apennines, 82 miles N. of Florence, and 135 SE. of Milan by rail. An irregular hexagon, it is inclosed by a high brick wall, 5 to 6 miles in extent, with twelve gates, and is intersected by the canal of Reno, while, on either side, the rivers Reno and Savena sweep past its walls. The streets in the newer parts of the city are spacious and well paved, with rich and varied colonnades, affording shelter alike from sun and rain; in the older portion, the streets are narrow and dirty, and the arcades correspondingly low and gloomy. The city is adorned with many fine palaces of the nobility, which are rich in fresco-paintings by the great masters. Pre-eminently worthy of notice are the Palazzo Pubblico, and the Palazzo del Podestà. The former contains some fine frescoed rooms and galleries; the latter is interesting as having been the prison and death-scene, in 1272, of Enzo, the son of the Emperor Frederick II., and also as containing the archives of the city. There are numerous and important charitable institutions. The great feature of Bologna, however, is its religious

edifices, which are remarkable both for the beauty of their architecture, and the abundance and splendour of the art-treasures they contain. It has more than 70 churches, the most remarkable of which are San Stefano, which is rich in relics, Madonnas, and Byzantine frescoes of the 11th and 12th centuries; San Petronio—which, though unfinished, is the largest church in the town—a noble specimen of Italian Gothic, with a meridian traced on the floor by the astronomer Cassini, and numerous masterpieces both in sculpture and in painting; San Domenico, where the founder of the order lived and died, and where his tomb has been richly ornamented by Michael Angelo and others; and the cathedral dedicated to St Peter, also rich in works of art. In the centre of the city are two remarkable leaning towers, constructed about the beginning of the 12th century: the Asinella, with a height of 274 feet, and an inclination of 3 feet 4 inches, and the Garisenda, with an elevation of 137 feet, and a lean of 8 feet 2 inches. The university of Bologna, the oldest in Europe, claims to have been founded in 425; it certainly dates as a law-school from the 11th century. Its reputation early became so great, chiefly on account of its school of jurisprudence, that students from all parts of Europe were attracted to it. In 1262 the number receiving instruction is stated to have been 10,000, and it was found necessary to appoint professors specially for the students from each country. Medicine has long been the principal study, and the discovery of Galvanism by one of its professors has shed a lustre on the university, which is also celebrated as the earliest school for the practice of dissection of the human body, as well as for the fact, that for centuries learned female professors have profected within its walls. Though the students now number less than 1500, the university still holds a first rank among Italian educational institutions; its eighth centenary was celebrated in 1888. Bologna also possesses an academy of music of some note (1805), at which Rossini studied. The university library contains 160,000 vols. and 6000 MSS., many of which are very rare and valuable, and there is besides a city library of 120,000 vols. The Accademia delle Belle Arti is particularly rich in the works of those native artists who founded the far-famed Bolognese school of painting, and it has also some fine specimens of other schools. Bologna has given 8 popes and more than 200 cardinals to the Church. There are some important manufactures, including silk goods, velvet, crape, wax candles, musical instruments, chemical products, paper, cards, and sausages almost as celebrated as its paintings. Pop. (1872) 115,957; (1881) 103,998; (1891) 147,000.

Bologna owes its origin, which is said to be much more remote than that of Rome, to the Etruscans, by whom it was called *Felsina*. It was afterwards, as *Bononia*, the chief town of the Boii, from whom it was taken by the Romans and made a colony (189 B.C.). After the fall of the Roman empire, it passed into the hands of the Longobards, from whom it was taken by the Franks. Charlemagne made it a free city, and the citizens were afterwards invested with the choice of their own judges, consuls, and magistrates. The feuds of the Guelph and Ghibelline factions led in 1506 to the downfall of the republic, and the supremacy of the papal see. In 1796 Bologna was taken by the French, and was constituted the chief town of the Cisalpine Republic; in 1815 it reverted to the pope. In 1848 the Austrians vainly attempted to obtain possession of the town; in the following year, however, they captured it after a ten days' siege. From the commencement of the Italian campaign of 1859, the Bolognese gave an active sympathy to

the national cause; intimated their intention of placing themselves under the rule of Victor Emmanuel; and when the question of annexation to Italy, or separate government, was submitted to the universal vote of the people, in March 1860, the votes for annexation were 1000 to 1.—The *Province of Bologna* forms part of the *compartimento* of Emilia. It is very fertile, and its numerous small streams and canals are largely utilised in the irrigation of rice-fields. Large numbers of silkworms are reared. Area, 1432 sq. m.; pop. (1892) 486,059. See Burton's *Etruscan Bologna* (1876). For the Bolognese School of Painting, see CARACCI, PAINTING.

Bologna Phial, or PHILOSOPHICAL PHIAL, is a short, thick, narrow glass vessel, close at one end, and open at the other, which the glass-blower prepares from each pot of metal before employing it in the fashioning of tumblers, glasses, bottles, &c. (see GLASS). It serves the purpose of enabling the glass-manufacturer to judge of the colour and other conditions of the fused glass or metal; and as the flask is not subjected to annealing, it is very friable, and a small angular fragment of any mineral allowed to drop into it, at once causes it to fly in pieces. It is curious to notice, however, that a Bologna phial will bear a very heavy blow on the outside without being fractured.

Bologna Stone, or BONONIAN STONE. In the end of the 16th or beginning of the 17th century, Vincent Casciorolo, a shoemaker of Bologna, made the very remarkable discovery that the mineral now known as heavy spar (barium sulphate), which is found near Bologna (as it is in a great many other places), when reduced to a fine powder mixed with gum, dried, and strongly heated in a covered crucible, is converted into a substance having the property of shining in the dark. Casciorolo mentioned his discovery (1602) to the alchemist Scipio Begatello and the mathematician Maginus, and the latter made the substance (first called by its discoverer 'capis solaris,' but soon from the place where it was prepared, 'the Bologna, or Bononian Stone') famous by the specimens which he sent about. Peter Potier (or Poteras), a French chemist resident in Bologna, first published (1622) a recipe for making it.

The substance is essentially sulphide of barium, but its phosphorescent character depends very much on the way in which it is prepared, and many processes have been described. It shines in the dark only if it has previously been shone on, seeming slowly to give out the light it has absorbed. The now well-known 'luminous paint' is made up of this or of other similar and similarly prepared sulphides. See PHOSPHORESCENCE.

Bolometer, an instrument invented (1881) by Professor Langley for the measurement of the intensity of radiant heat—essentially a Wheatstone's Bridge (see ELECTRICITY, Vol. IV. p. 268), arranged so that no current passes through the galvanometer. The arms of the bridge are made of a substance the resistance of which varies greatly with the temperature. Hence, if one arm be exposed to radiation from which the other is screened, the galvanometer needle will be at once deflected. The instrument may be made much more sensitive than a thermopile. A good one can measure variations of temperature of $\frac{1}{100000}$ th of a degree centigrade, and can detect a variation of $\frac{1}{1000000}$ th.

Bolor-Tagh is a lofty border-ridge of the Pamir plateau, ranging SW. to NE., which falls abruptly to Kashgaria (see ASIA, PAMIR, TURKESTAN). There was near this an ancient kingdom of Bolor; see *Proceedings of Geographical Society for 1881*.

Bolse'na (ancient *Volsinii*), a town in the province of Rome, on the north shore of the Lake of Bolsena (*Lacus Volsiniensis*), 20 miles NNW. of Viterbo. It now has only 2200 inhabitants; but prior to 280 B.C. it was a place of great importance, forming one of the twelve Etruscan cities. At Bolsena, in 1263, a doubting priest was said to have been convinced of the truth of the doctrine of transubstantiation, by witnessing the flow of blood from the Host he had just consecrated; and in commemoration of this miracle (the subject of a masterpiece), Urban IV. instituted, in 1264, the festival of Corpus Christi. Half a mile from Bolsena are a few traces of the Etruscan city, and many fragments of the later Roman one remain.—The Lake of Bolsena is a fine expanse of water about 10 miles long and 8 broad, but its shores are very unhealthy. It occupies a volcanic hollow. The Marta River carries its waters into the Mediterranean. It has two islands, Bisentina and Martana, which were favourite autumnal retreats of Pope Leo X. See ETRURIA.

Bolsward, an old town of Friesland, 15 miles SW. from Leeuwarden. It has a fine Gothic church. Pop. 5789.
